WARNING: Many of the compounds and chemical reactions described or pictured in this book are hazardous. Do not attempt any experiment pictured or implied in the text except with permission in an authorized laboratory setting and under adequate supervision.

Brief Table of Contents

1 Matter: Its Properties and Measurement **1**
2 Atoms and the Atomic Theory **34**
3 Chemical Compounds **68**
4 Chemical Reactions **111**
5 Introduction to Reactions in Aqueous Solutions **151**
6 Gases **192**
7 Thermochemistry **241**
8 Electrons in Atoms **294**
9 The Periodic Table and Some Atomic Properties **360**
10 Chemical Bonding I: Basic Concepts **395**
11 Chemical Bonding II: Additional Aspects **449**
12 Intermolecular Forces: Liquids and Solids **498**
13 Solutions and Their Physical Properties **557**
14 Chemical Kinetics **602**
15 Principles of Chemical Equilibrium **665**
16 Acids and Bases **697**
17 Additional Aspects of Acid–Base Equilibria **745**
18 Solubility and Complex-Ion Equilibria **784**
19 Spontaneous Change: Entropy and Gibbs Energy **819**
20 Electrochemistry **863**
21 Chemistry of the Main-Group Elements I: Groups 1, 2, 13, and 14 **917**
22 Chemistry of the Main-Group Elements II: Groups 18, 17, 16, 15, and Hydrogen **976**
23 The Transition Elements **1031**
24 Complex Ions and Coordination Compounds **1069**
25 Nuclear Chemistry **1111**
26 Structures of Organic Compounds **1147**
27 Reactions of Organic Compounds **1208**
28 Chemistry of the Living State **1266**

APPENDICES

A Mathematical Operations **A1**
B Some Basic Physical Concepts **A11**
C SI Units **A15**
D Data Tables **A17**
E Concept Maps **A37**
F Glossary **A39**
G Answers to Concept Assessment Questions **A55**

Contents

About the Authors xiv
Preface xv

1 Matter: Its Properties and Measurement 1

1-1 The Scientific Method 2
1-2 Properties of Matter 4
1-3 Classification of Matter 5
1-4 Measurement of Matter: SI (Metric) Units 8
1-5 Density and Percent Composition: Their Use in Problem Solving 13
1-6 Uncertainties in Scientific Measurements 18
1-7 Significant Figures 19
Summary 23
Integrative Example 24
Exercises 26
Integrative and Advanced Exercises 29
Feature Problems 31
Self-Assessment Exercises 32

2 Atoms and the Atomic Theory 34

2-1 Early Chemical Discoveries and the Atomic Theory 35
2-2 Electrons and Other Discoveries in Atomic Physics 38
2-3 The Nuclear Atom 42
2-4 Chemical Elements 44
2-5 Atomic Mass 48
2-6 Introduction to the Periodic Table 51
2-7 The Concept of the Mole and the Avogadro Constant 54
2-8 Using the Mole Concept in Calculations 56
Summary 59
Integrative Example 59
Exercises 60
Integrative and Advanced Exercises 64
Feature Problems 65
Self-Assessment Exercises 66

3 Chemical Compounds 68

3-1 Types of Chemical Compounds and Their Formulas 69
3-2 The Mole Concept and Chemical Compounds 73
3-3 Composition of Chemical Compounds 76
3-4 Oxidation States: A Useful Tool in Describing Chemical Compounds 84
3-5 Naming Compounds: Organic and Inorganic Compounds 86
3-6 Names and Formulas of Inorganic Compounds 87
3-7 Names and Formulas of Organic Compounds 94
Summary 100
Integrative Example 101
Exercises 103
Integrative and Advanced Exercises 107
Feature Problems 108
Self-Assessment Exercises 110

4 Chemical Reactions 111

4-1 Chemical Reactions and Chemical Equations 112
4-2 Chemical Equations and Stoichiometry 116
4-3 Chemical Reactions in Solution 123
4-4 Determining the Limiting Reactant 129
4-5 Other Practical Matters in Reaction Stoichiometry 132
Summary 138
Integrative Example 139
Exercises 140
Feature Problems 148
Self-Assessment Exercises 149

5 Introduction to Reactions in Aqueous Solutions 151

5-1 The Nature of Aqueous Solutions 152
5-2 Precipitation Reactions 156
5-3 Acid–Base Reactions 160
5-4 Oxidation–Reduction Reactions: Some General Principles 165
5-5 Balancing Oxidation–Reduction Equations 170
5-6 Oxidizing and Reducing Agents 175
5-7 Stoichiometry of Reactions in Aqueous Solutions: Titrations 177
Summary 181
Integrative Example 182
Exercises 183
Integrative and Advanced Exercises 187
Feature Problems 189
Self-Assessment Exercises 191

6 Gases 192

6-1 Properties of Gases: Gas Pressure 193
6-2 The Simple Gas Laws 198
6-3 Combining the Gas Laws: The Ideal Gas Equation and the General Gas Equation 204
6-4 Applications of the Ideal Gas Equation 207
6-5 Gases in Chemical Reactions 210
6-6 Mixtures of Gases 212
6-7 Kinetic-Molecular Theory of Gases 216
6-8 Gas Properties Relating to the Kinetic-Molecular Theory 223
6-9 Nonideal (Real) Gases 226
Summary 229
Integrative Example 230
Exercises 231
Integrative and Advanced Exercises 236
Feature Problems 238
Self-Assessment Exercises 240

7 Thermochemistry 241

7-1 Getting Started: Some Terminology 242
7-2 Heat 244
7-3 Heats of Reaction and Calorimetry 248
7-4 Work 252
7-5 The First Law of Thermodynamics 255
7-6 Heats of Reaction: ΔU and ΔH 259
7-7 Indirect Determination of ΔH: Hess's Law 266
7-8 Standard Enthalpies of Formation 268
7-9 Fuels as Sources of Energy 275
Summary 281
Integrative Example 282
Exercises 283
Integrative and Advanced Exercises 289
Feature Problems 291
Self-Assessment Exercises 292

8 Electrons in Atoms 294

8-1 Electromagnetic Radiation 295
8-2 Atomic Spectra 300
8-3 Quantum Theory 302
8-4 The Bohr Atom 307
8-5 Two Ideas Leading to a New Quantum Mechanics 313
8-6 Wave Mechanics 317
8-7 Quantum Numbers and Electron Orbitals 324
8-8 Interpreting and Representing the Orbitals of the Hydrogen Atom 327
8-9 Electron Spin: A Fourth Quantum Number 333
8-10 Multielectron Atoms 336

8-11 Electron Configurations 339
8-12 Electron Configurations and the Periodic Table 344
Summary 348
Integrative Example 349
Exercises 351
Integrative and Advanced Exercises 357
Feature Problems 358
Self-Assessment Exercises 359

9 The Periodic Table and Some Atomic Properties 360

9-1 Classifying the Elements: The Periodic Law and the Periodic Table 361
9-2 Metals and Nonmetals and Their Ions 364
9-3 Sizes of Atoms and Ions 367
9-4 Ionization Energy 374
9-5 Electron Affinity 378
9-6 Magnetic Properties 379
9-7 Periodic Properties of the Elements 381
Summary 386
Integrative Example 386
Exercises 389
Integrative and Advanced Exercises 391
Feature Problems 392
Self-Assessment Exercises 393

10 Chemical Bonding I: Basic Concepts 395

10-1 Lewis Theory: An Overview 396
10-2 Covalent Bonding: An Introduction 399
10-3 Polar Covalent Bonds and Electrostatic Potential Maps 402
10-4 Writing Lewis Structures 408
10-5 Resonance 416
10-6 Exceptions to the Octet Rule 418
10-7 Shapes of Molecules 421
10-8 Bond Order and Bond Lengths 433
10-9 Bond Energies 434
Summary 438
Integrative Example 439
Exercises 440
Integrative and Advanced Exercises 446
Feature Problems 447
Self-Assessment Exercises 448

11 Chemical Bonding II: Additional Aspects 449

11-1 What a Bonding Theory Should Do 450
11-2 Introduction to the Valence-Bond Method 451
11-3 Hybridization of Atomic Orbitals 453
11-4 Multiple Covalent Bonds 461
11-5 Molecular Orbital Theory 465
11-6 Delocalized Electrons: Bonding in the Benzene Molecule 474
11-7 Bonding in Metals 480
11-8 Some Unresolved Issues: Can Electron Charge-Density Plots Help? 484
Summary 489
Integrative Example 489
Exercises 491
Integrative and Advanced Exercises 494
Feature Problems 495
Self-Assessment Exercises 497

12 Intermolecular Forces: Liquids and Solids 498

12-1 Intermolecular Forces 499
12-2 Some Properties of Liquids 508
12-3 Some Properties of Solids 520
12-4 Phase Diagrams 522
12-5 Network Covalent Solids and Ionic Solids 526

12-6 Crystal Structures **530**
12-7 Energy Changes in the Formation of Ionic Crystals **542**
Summary **545** Integrative Example **546**
Exercises **547** Integrative and Advanced Exercises **552**
Feature Problems **554** Self-Assessment Exercises **556**

13 Solutions and Their Physical Properties 557

13-1 Types of Solutions: Some Terminology **558**
13-2 Solution Concentration **558**
13-3 Intermolecular Forces and the Solution Process **562**
13-4 Solution Formation and Equilibrium **567**
13-5 Solubilities of Gases **570**
13-6 Vapor Pressures of Solutions **573**
13-7 Osmotic Pressure **577**
13-8 Freezing-Point Depression and Boiling-Point Elevation of Nonelectrolyte Solutions **581**
13-9 Solutions of Electrolytes **584**
13-10 Colloidal Mixtures **587**
Summary **590** Integrative Example **591**
Exercises **592** Integrative and Advanced Exercises **597**
Feature Problems **599** Self-Assessment Exercises **600**

14 Chemical Kinetics 602

14-1 The Rate of a Chemical Reaction **603**
14-2 Measuring Reaction Rates **605**
14-3 Effect of Concentration on Reaction Rates: The Rate Law **608**
14-4 Zero-Order Reactions **611**
14-5 First-Order Reactions **612**
14-6 Second-Order Reactions **619**
14-7 Reaction Kinetics: A Summary **620**
14-8 Theoretical Models for Chemical Kinetics **622**
14-9 The Effect of Temperature on Reaction Rates **626**
14-10 Reaction Mechanisms **629**
14-11 Catalysis **637**
Summary **642** Integrative Example **643**
Exercises **645** Integrative and Advanced Exercises **650**
Feature Problems **652** Self-Assessment Exercises **654**

15 Principles of Chemical Equilibrium 665

15-1 Dynamic Equilibrium **656**
15-2 The Equilibrium Constant Expression **656**
15-3 Relationships Involving Equilibrium Constants **663**
15-4 The Magnitude of an Equilibrium Constant **669**
15-5 The Reaction Quotient, *Q*: Predicting the Direction of Net Change **670**
15-6 Altering Equilibrium Conditions: Le Châtelier's Principle **673**
15-7 Equilibrium Calculations: Some Illustrative Examples **679**
Summary **686** Integrative Example **686**
Exercises **688** Integrative and Advanced Excercises **693**
Feature Problems **694** Self-Assessment Exercises **695**

16 Acids and Bases 697

16-1 Arrhenius Theory: A Brief Review **698**
16-2 Brønsted–Lowry Theory of Acids and Bases **698**
16-3 Self-Ionization of Water and the pH Scale **703**
16-4 Strong Acids and Strong Bases **706**
16-5 Weak Acids and Weak Bases **708**
16-6 Polyprotic Acids **717**
16-7 Ions as Acids and Bases **723**
16-8 Molecular Structure and Acid–Base Behavior **727**
16-9 Lewis Acids and Bases **732**
Summary **736**
Integrative Example **736**
Exercises **738**
Integrative and Advanced Exercises **742**
Feature Problems **743**
Self-Assessment Exercises **744**

17 Additional Aspects of Acid–Base Equilibria 745

17-1 Common-Ion Effect in Acid–Base Equilibria **746**
17-2 Buffer Solutions **750**
17-3 Acid–Base Indicators **759**
17-4 Neutralization Reactions and Titration Curves **762**
17-5 Solutions of Salts of Polyprotic Acids **770**
17-6 Acid–Base Equilibrium Calculations: A Summary **771**
Summary **773**
Integrative Example **773**
Exercises **775**
Integrative and Advanced Exercises **779**
Feature Problems **782**
Self-Assessment Exercises **783**

18 Solubility and Complex-Ion Equilibria 784

18-1 Solubility Product Constant, K_{sp} **785**
18-2 Relationship Between Solubility and K_{sp} **786**
18-3 Common-Ion Effect in Solubility Equilibria **788**
18-4 Limitations of the K_{sp} Concept **790**
18-5 Criteria for Precipitation and Its Completeness **792**
18-6 Fractional Precipitation **795**
18-7 Solubility and pH **797**
18-8 Equilibria Involving Complex Ions **799**
18-9 Qualitative Cation Analysis **805**
Summary **810**
Integrative Example **810**
Exercises **812**
Integrative and Advanced Exercises **815**
Feature Problems **816**
Self-Assessment Exercises **817**

19 Spontaneous Change: Entropy and Gibbs Energy 819

19-1 Spontaneity: The Meaning of Spontaneous Change **820**
19-2 The Concept of Entropy **821**
19-3 Evaluating Entropy and Entropy Changes **827**
19-4 Criteria for Spontaneous Change: The Second Law of Thermodynamics **832**
19-5 Standard Gibbs Energy Change, ΔG° **836**
19-6 Gibbs Energy Change and Equilibrium **837**
19-7 ΔG° and K as Functions of Temperature **848**
19-8 Coupled Reactions **851**
Summary **852**
Integrative Example **853**
Exercises **854**
Integrative and Advanced Exercises **858**
Feature Problems **860**
Self-Assessment Exercises **861**

20 Electrochemistry 863

20-1 Electrode Potentials and Their Measurement **864**
20-2 Standard Electrode Potentials **869**
20-3 E_{cell}, ΔG, and K **874**
20-4 E_{cell} as a Function of Concentrations **880**
20-5 Batteries: Producing Electricity Through Chemical Reactions **888**
20-6 Corrosion: Unwanted Voltaic Cells **894**
20-7 Electrolysis: Causing Nonspontaneous Reactions to Occur **896**
20-8 Industrial Electrolysis Processes **900**
Summary **904** Integrative Example **905**
Exercises **907** Integrative and Advanced Exercises **912**
Feature Problems **914** Self-Assessment Exercises **915**

21 Chemistry of the Main-Group Elements I: Groups 1, 2, 13, and 14 917

21-1 Periodic Trends and Charge Density **918**
21-2 Group 1: The Alkali Metals **920**
21-3 Group 2: The Alkaline Earth Metals **933**
21-4 Group 13: The Boron Family **941**
21-5 Group 14: The Carbon Family **951**
Summary **968** Integrative Example **969**
Exercises **970** Integrative and Advanced Exercises **972**
Feature Problems **974** Self-Assessment Exercises **974**

22 Chemistry of the Main-Group Elements II: Groups 18, 17, 16, 15, and Hydrogen 976

22-1 Periodic Trends in Bonding **977**
22-2 Group 18: The Noble Gases **979**
22-3 Group 17: The Halogens **985**
22-4 Group 16: The Oxygen Family **994**
22-5 Group 15: The Nitrogen Family **1004**
22-6 Hydrogen: A Unique Element **1017**
Summary **1021** Integrative Example **1022**
Exercises **1023** Integrative and Advanced Exercises **1026**
Feature Problems **1028** Self-Assessment Exercises **1029**

23 The Transition Elements 1031

23-1 General Properties **1032**
23-2 Principles of Extractive Metallurgy **1037**
23-3 Metallurgy of Iron and Steel **1044**
23-4 First-Row Transition Metal Elements: Scandium to Manganese **1046**
23-5 The Iron Triad: Iron, Cobalt, and Nickel **1052**
23-6 Group 11: Copper, Silver, and Gold **1054**
23-7 Group 12: Zinc, Cadmium, and Mercury **1056**
23-8 Lanthanides **1059**
23-9 High-Temperature Superconductors **1059**
Summary **1062** Integrative Example **1062**
Exercises **1063** Integrative and Advanced Exercises **1066**
Feature Problems **1067** Self-Assessment Exercises **1068**

24 Complex Ions and Coordination Compounds 1069

24-1 Werner's Theory of Coordination Compounds: An Overview 1070
24-2 Ligands 1072
24-3 Nomenclature 1075
24-4 Isomerism 1076
24-5 Bonding in Complex Ions: Crystal Field Theory 1083
24-6 Magnetic Properties of Coordination Compounds and Crystal Field Theory 1088
24-7 Color and the Colors of Complexes 1090
24-8 Aspects of Complex-Ion Equilibria 1093
24-9 Acid–Base Reactions of Complex Ions 1095
24-10 Some Kinetic Considerations 1096
24-11 Applications of Coordination Chemistry 1097
Summary 1102
Integrative Example 1103
Exercises 1104
Integrative and Advanced Exercises 1106
Feature Problems 1108
Self-Assessment Exercises 1109

25 Nuclear Chemistry 1111
25-1 Radioactivity 1112
25-2 Naturally Occurring Radioactive Isotopes 1115
25-3 Nuclear Reactions and Artificially Induced Radioactivity 1117
25-4 Transuranium Elements 1118
25-5 Rate of Radioactive Decay 1119
25-6 Energetics of Nuclear Reactions 1125
25-7 Nuclear Stability 1128
25-8 Nuclear Fission 1130
25-9 Nuclear Fusion 1133
25-10 Effect of Radiation on Matter 1134
25-11 Applications of Radioisotopes 1137
Summary 1139
Integrative Example 1140
Exercises 1141
Integrative and Advanced Exercises 1144
Feature Problems 1145
Self-Assessment Exercises 1146

26 Structures of Organic Compounds 1147
26-1 Organic Compounds and Structures: An Overview 1148
26-2 Alkanes 1155
26-3 Cycloalkanes 1161
26-4 Stereoisomerism in Organic Compounds 1168
26-5 Alkenes and Alkynes 1175
26-6 Aromatic Hydrocarbons 1179
26-7 Organic Compounds Containing Functional Groups 1181
26-8 From Molecular Formula to Molecular Structure 1192
Summary 1195
Integrative Example 1197
Exercises 1198
Integrative and Advanced Exercises 1204
Feature Problem 1205
Self-Assessment Exercises 1207

27 Reactions of Organic Compounds 1208
27-1 Organic Reactions: An Introduction 1209
27-2 Introduction to Nucleophilic Substitution Reactions 1211
27-3 Introduction to Elimination Reactions 1225
27-4 Reactions of Alcohols 1234
27-5 Introduction to Addition Reactions: Reactions of Alkenes 1239
27-6 Electrophilic Aromatic Substitution 1244

27-7 Reactions of Alkanes 1248
27-8 Polymers and Polymerization Reactions 1250
27-9 Synthesis of Organic Compounds 1254
Summary 1256 Integrative Example 1257
Exercises 1259 Integrative and Advanced Exercises 1263
Feature Problem 1264 Self-Assessment Exercises 1265

28 Chemistry of the Living State 1266
28-1 Chemical Structure of Living Matter: An Overview 1267
28-2 Lipids 1268
28-3 Carbohydrates 1271
28-4 Proteins 1279
28-5 Aspects of Metabolism 1286
28-6 Nucleic Acids 1292
Summary 1295 Integrative Example 1296
Exercises 1297 Integrative and Advanced Exercises 1300
Feature Problems 1301 Self-Assessment Exercises 1302

About the Authors

Ralph H. Petrucci

Ralph Petrucci received his B.S. in Chemistry from Union College, Schenectady, NY, and his Ph.D. from the University of Wisconsin–Madison. Following ten years of teaching, research, consulting, and directing the NSF Institutes for Secondary School Science Teachers at Case Western Reserve University, Cleveland, OH, Dr. Petrucci joined the planning staff of the new California State University campus at San Bernardino in 1964. There, in addition to his faculty appointment, he served as Chairman of the Natural Sciences Division and Dean of Academic Planning. Professor Petrucci, now retired from teaching, is also a coauthor of *General Chemistry* with John W. Hill, Terry W. McCreary, and Scott S. Perry.

F. Geoffrey Herring

Geoff Herring received both his B.Sc. and his Ph.D. in Physical Chemistry, from the University of London. He is currently a Professor Emeritus in the Department of Chemistry of the University of British Columbia, Vancouver. Dr. Herring has research interests in biophysical chemistry and has published more than 100 papers in physical chemistry and chemical physics. Recently, Dr. Herring has undertaken studies in the use of information technology and interactive engagement methods in teaching general chemistry with a view to improving student comprehension and learning. Dr. Herring has taught chemistry from undergraduate to graduate levels for 30 years and has twice been the recipient of the Killam Prize for Excellence in Teaching.

Jeffry D. Madura

Jeffry D. Madura is a Professor in the Department of Chemistry and Biochemistry at Duquesne University located in Pittsburgh, PA. He earned a B.A. from Thiel College in 1980 and a Ph.D. in Physical Chemistry from Purdue University in 1985. The Ph.D. was followed by a postdoctoral fellowship in biophysics with Professor J. Andrew McCammon at the University of Houston. Dr. Madura's research interests are in computational chemistry and biophysics. He has published more than 80 papers in physical chemistry and chemical physics. Dr. Madura has taught chemistry from undergraduate to graduate levels for 20 years and was the recipient of a Dreyfus Teacher-Scholar Award. He also received the Bayer School of Natural and Environmental Sciences and the Duquesne University Presidential Award for Excellence in Scholarship in 2007.

Carey Bissonnette

Carey Bissonnette is Continuing Lecturer in the Department of Chemistry at the University of Waterloo, Ontario. He received his B.Sc. from the University of Waterloo in 1989 and his Ph.D. in 1993 from the University of Cambridge in England. His research interests are in the development of methods for modeling dynamical processes of polyatomic molecules in the gas phase. He has won awards for excellence in teaching, including the University of Waterloo's Distinguished Teacher Award in 2005. Dr. Bissonnette has made extensive use of technology in both the classroom and the laboratory to create an interactive environment for his students to learn and explore. For the past several years, he has been actively engaged in undergraduate curriculum development, high-school liaison activities, and the coordination of the university's high-school chemistry contests, which are written each year by students around the world.

Preface

"Know your audience." For this new edition, we have tried to follow this important advice by attending even more to the needs of students who are taking a serious journey through this material. We also know that most general chemistry students have career interests not in chemistry but in other areas such as biology, medicine, engineering, environmental science, and agricultural sciences. And we understand that general chemistry will be the only university or college chemistry course for some students, and thus their only opportunity to learn some practical applications of chemistry. We have designed this book for all these students.

Students of this text should have already studied some chemistry. But those with no prior background and those who could use a refresher will find that the early chapters develop fundamental concepts from the most elementary ideas. Students who do plan to become professional chemists will also find opportunities in the text to pursue their own special interests.

The typical student may need help identifying and applying principles and visualizing their physical significance. The pedagogical features of this text are designed to provide this help. At the same time, we hope the text serves to sharpen student skills in problem solving and critical thinking. Thus, we have tried to strike the proper balances between principles and applications, qualitative and quantitative discussions, and rigor and simplification.

Throughout the text and on the Mastering Chemistry site (www.masteringchemistry.com) we provide real-world examples to enhance the discussion. Examples relevant to the biological sciences, engineering, and the environmental sciences will be found in numerous places. This should help to bring the chemistry alive for these students and help them understand its relevance to their career interests. It also, in most cases, should help them master core concepts.

ORGANIZATION

In this edition we retain the core organization of the ninth edition of this text, but with additional depth and breadth of coverage of material in several areas. After a brief overview of core concepts in Chapter 1, we introduce atomic theory, including the periodic table, in Chapter 2. The periodic table is an extraordinarily useful tool, and presenting it early allows us to use the periodic table in new ways throughout the early chapters of the text. In Chapter 3 we introduce chemical compounds and their stoichiometry. Organic compounds are included in this presentation. The early introduction of organic compounds allows us to use organic examples throughout the book. Chapters 4 and 5 introduce chemical reactions. We discuss gases in Chapter 6, partly because they are familiar to students (which helps them build confidence), but also because some instructors prefer to cover this material early to better integrate their lecture and lab programs. Note that Chapter 6 can easily be deferred for coverage with the other states of matter, in Chapter 12. In Chapter 8 we delve more deeply into wave mechanics, although we do so in a way that allows omission of this material at the instructor's discretion. As with previous editions, we have emphasized real-world chemistry in the final chapters that cover descriptive chemistry (Chapters 21–24), and we have tried to make this material easy to bring forward into earlier parts of the text. Moreover, many topics in these chapters can be covered selectively, without requiring the study of entire chapters.

The text ends with comprehensive chapters on organic chemistry (Chapters 26 and 27) and biochemistry (Chapter 28).

CHANGES TO THIS EDITION

For this edition, we have strengthened the pedagogical apparatus and increased the depth of coverage in selected areas—all in accordance with contemporary thoughts about how best to teach general chemistry. We have also made a number of smaller organizational changes to improve the flow of information. The following summarizes the major improvements made throughout the book.

- *Logical approach to solving problems.* All worked examples are presented consistently throughout the text by using a tripartite structure of Analyze-Solve-Assess. This presentation not only encourages students to use a logical approach in solving problems but also provides them with a way to start when they are trying to solve a problem that may seem, at first, impossibly difficult. The approach is used implicitly by those who have had plenty of practice solving problems; but for those who are just starting out, the Analyze-Solve-Assess structure will serve to remind students to (1) analyze the information and plan a strategy, (2) implement the strategy, and (3) check or assess their answer to ensure that it is a reasonable one.
- *Integrative Practice Examples and End of Chapter Exercises.* Users of previous editions have given us very positive feedback about the quality of the integrative examples at the end of each chapter and the variety of the end-of-chapter exercises. We have added two practice examples (Practice Example A and Practice Example B) to every Integrative Example in the text. Rather than replace end-of-chapter exercises with new exercises, we have opted in most chapters to increase the number of exercises. In most chapters, at least 10 new exercises have been added; and in many chapters, 20 or more exercises have been added.
- *Use of IUPAC recommendations.* We are pleased that our book serves the needs of instructors and students around the globe. Because communication among scientists in general, and chemists in particular, is made easier when we agree to use the same terms and notations, we have decided to follow—with relatively few exceptions—recommendations made by the International Union of Pure and Applied Chemistry (IUPAC). In particular, the version of the periodic table that now appears throughout the text is based on the one currently endorsed by IUPAC. The IUPAC-endorsed version places the elements lanthanum (La) and actinium (Ac) in the lanthanides and actinides series, respectively, rather than in group 3. Interestingly, almost every other chemistry book still uses the old version of the periodic table, even though the proper placement of La and Ac has been known for more than 20 years!

We have also made the following important changes in specific chapters and appendices:

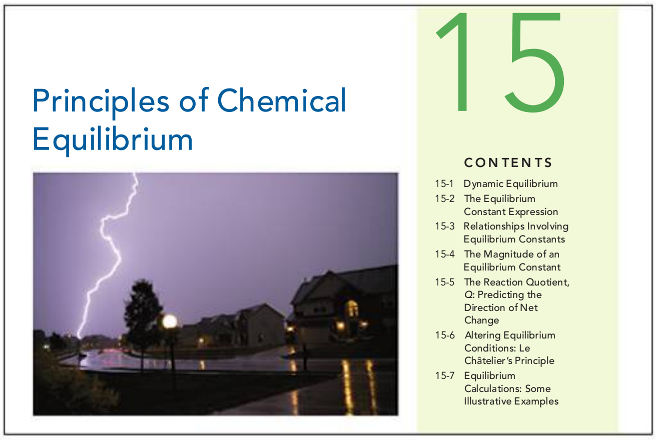
- In Chapters 1 to 6, many problems are solved by using both a stepwise approach and a conversion pathway approach. Students with no chemistry background may be intimidated by the conversion pathway approach and may prefer a stepwise approach. Those who require only a refresher will likely prefer and use the conversion pathway approach. We hope that the needs of both instructors and students will be well served by showing both approaches in the early chapters.
- In Chapter 6 (Gases), we have changed the definition of standard temperature and pressure (STP) to conform to the IUPAC recommendations.

Also, we have added discussion about the molar volumes of gases and the distribution of molecular speeds. The discussion about the distribution of molecular speeds may be used as a springboard for justifying the Arrhenius form of the rate constant in Chapter 14 Chemical Kinetics.

- In Chapter 8 (Electrons in Atoms), we have put the material on the particle-in-a box into a separate section that can be used, or excluded, at the instructor's discretion. The discussion has been expanded slightly to illustrate how wave functions are used to make probability statements for an electron in a particular state.
- In Chapter 10 (Chemical Bonding I: Basic Concepts), we have introduced the dash-and-wedge symbolism for representing three-dimensional structures of molecules, and this symbolism is used throughout the remainder of the text. Also, we have added a new Are You Wondering? box comparing oxidation states and formal charges.
- Chapter 12 (Intermolecular Forces: Liquids and Solids), has been reorganized so that intermolecular forces are discussed first. Trends in the properties of liquids and solids are then discussed in terms of the intermolecular forces contributing to the attraction among the entities making up the substance.
- In Chapter 14 (Chemical Kinetics), we have adopted the IUPAC recommendation for defining reaction rates, which takes into account the stoichiometric coefficients of the balanced chemical equation. We have also included a new Are You Wondering? box that provides a molecular interpretation of reaction progress.
- In Chapter 15 (Principles of Chemical Equilibrium), we have expanded the discussion of the relationships among activities, pressure and concentrations, and also among K, K_p and K_c.
- In Chapter 16 (Acids and Bases), we have used curved arrows in a manner that is consistent with their use in organic chemistry, that is, to emphasize the movement of electron pairs in acid–base reactions. Also, we present an improved and modernized discussion of the connection between molecular structure and acid strength.
- In Chapter 20 (Electrochemistry), we have made some changes in notation that are recommended by IUPAC. Most importantly, we introduce the concept of *electron number*, z, and use it in place of n in the Nernst equation and other equations.
- Chapter 21 (Chemistry of the Main-Group Elements I: Groups 1, 2, 13, and 14); and Chapter 22 (Chemistry of the Main-Group Elements II: Groups 18, 17, 16, 15, and Hydrogen) have been updated to include discussion of interesting and important materials, such as crown ether complexes, zeolites, and graphene. In Chapter 21, we introduce the concept of charge density and use it throughout these two chapters to rationalize similarities and differences in properties of elements.
- We have devoted two chapters to organic chemistry. Chapter 26 (Structures of Organic Compounds) focuses on the structures, conformations, preparation, and uses of organic compounds. Chapter 27 (Reactions of Organic Compounds) focuses on a few important types of reactions and their mechanisms. In examining these reactions, emphasis is placed on concepts introduced earlier in the text, such as acid or base strength, electronegativity, and polarizability.
- In Appendix D, we have added the molar heat capacity for each of the substances listed in Table D.2 (Thermodynamic Properties of Substances at 298.15 K). We have also provided a new Table D.5 of Isotopic Masses and Their Abundance.

FEATURES OF THIS EDITION

We have made a careful effort with this edition to incorporate features that will facilitate the teaching and learning of chemistry.



Principles of Chemical Equilibrium

15

CONTENTS

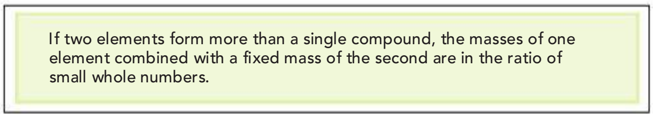
15-1 Dynamic Equilibrium
15-2 The Equilibrium Constant Expression
15-3 Relationships Involving Equilibrium Constants
15-4 The Magnitude of an Equilibrium Constant
15-5 The Reaction Quotient, Q: Predicting the Direction of Net Change
15-6 Altering Equilibrium Conditions: Le Châtelier's Principle
15-7 Equilibrium Calculations: Some Illustrative Examples

Chapter Opener

Each chapter opens with listing of the main headings to provide a convenient overview of the chapter's **Contents**.

Key Terms

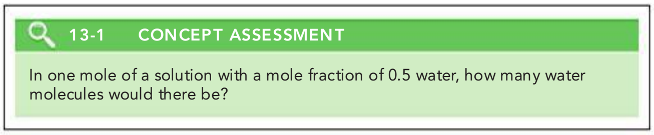
Key terms are boldfaced where they are defined in the text. A **Glossary** of key terms with their definitions is presented in Appendix F.



If two elements form more than a single compound, the masses of one element combined with a fixed mass of the second are in the ratio of small whole numbers.

Highlighted Boxes

Significant equations, concepts, and rules are highlighted against a color background for easy reference.

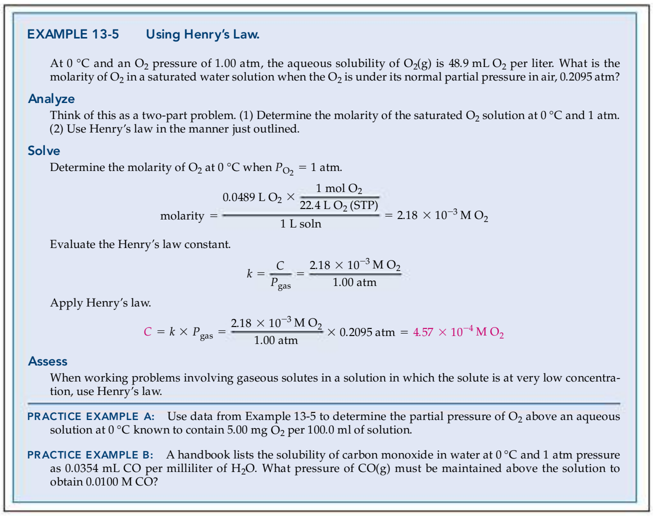


13-1 CONCEPT ASSESSMENT

In one mole of a solution with a mole fraction of 0.5 water, how many water molecules would there be?

Concept Assessment

Concept Assessment Questions (many of which are qualitative) are distributed throughout the body of the chapters. They enable students to test their understanding of basic concepts before proceeding further. Full solutions are provided near the back of the book in Appendix G.



EXAMPLE 13-5 Using Henry's Law.

At 0 °C and an O_2 pressure of 1.00 atm, the aqueous solubility of $O_2(g)$ is 48.9 mL O_2 per liter. What is the molarity of O_2 in a saturated water solution when the O_2 is under its normal partial pressure in air, 0.2095 atm?

Analyze

Think of this as a two-part problem. (1) Determine the molarity of the saturated O_2 solution at 0 °C and 1 atm. (2) Use Henry's law in the manner just outlined.

Solve

Determine the molarity of O_2 at 0 °C when $P_{O_2} = 1$ atm.

$$\text{molarity} = \frac{0.0489\text{ L O}_2 \times \dfrac{1\text{ mol O}_2}{22.4\text{ L O}_2\text{ (STP)}}}{1\text{ L soln}} = 2.18 \times 10^{-3}\text{ M O}_2$$

Evaluate the Henry's law constant.

$$k = \frac{C}{P_{\text{gas}}} = \frac{2.18 \times 10^{-3}\text{ M O}_2}{1.00\text{ atm}}$$

Apply Henry's law.

$$C = k \times P_{\text{gas}} = \frac{2.18 \times 10^{-3}\text{ M O}_2}{1.00\text{ atm}} \times 0.2095\text{ atm} = 4.57 \times 10^{-4}\text{ M O}_2$$

Assess

When working problems involving gaseous solutes in a solution in which the solute is at very low concentration, use Henry's law.

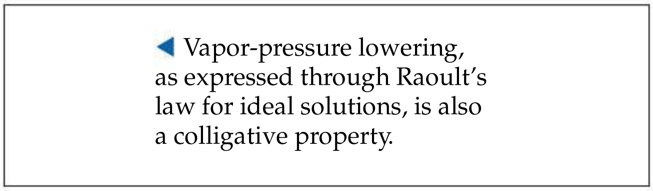
PRACTICE EXAMPLE A: Use data from Example 13-5 to determine the partial pressure of O_2 above an aqueous solution at 0 °C known to contain 5.00 mg O_2 per 100.0 ml of solution.

PRACTICE EXAMPLE B: A handbook lists the solubility of carbon monoxide in water at 0 °C and 1 atm pressure as 0.0354 mL CO per milliliter of H_2O. What pressure of CO(g) must be maintained above the solution to obtain 0.0100 M CO?

Examples with Practice Examples A and B

Worked-Out Examples throughout the text illustrate how to apply the concepts. In many instances, a drawing or photograph is included to help students visualize what is going on in the problem. More importantly, all worked-out Examples now follow a tripartite structure of **Analyze-Solve-Assess** to encourage students to adopt a logical approach to problem solving.

Two **Practice Examples** are provided for each worked-out Example. The first, **Practice Example A**, provides immediate practice in a problem very similar to the given Example. The second, **Practice Example B**, often takes the student one step further than the given Example and is similar to the end-of chapter problems in terms of level of difficulty. Answers to all the Practice Examples are given on the **MasteringChemistry™** site (www.masteringchemistry.com).



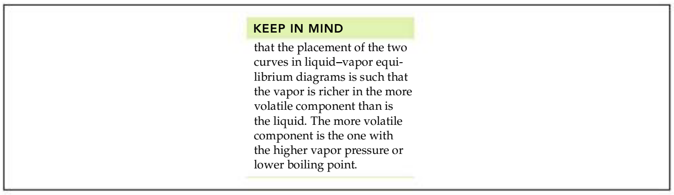
◀ Vapor-pressure lowering, as expressed through Raoult's law for ideal solutions, is also a colligative property.

Marginal Glosses

Marginal Glosses help clarify important points.

Keep In Mind Notes

Keep In Mind margin notes remind students about ideas introduced earlier in the text that are important to an understanding of the topic under discussion. In some instances they also warn students about common pitfalls.

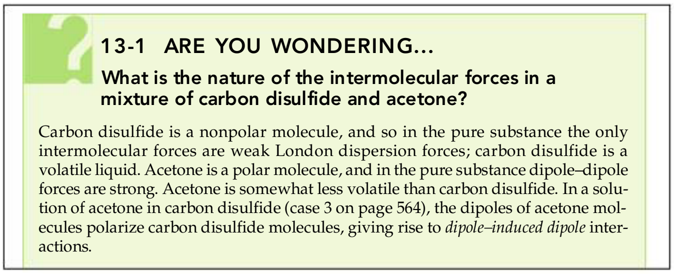


KEEP IN MIND

that the placement of the two curves in liquid–vapor equilibrium diagrams is such that the vapor is richer in the more volatile component than is the liquid. The more volatile component is the one with the higher vapor pressure or lower boiling point.

Are You Wondering?

Are You Wondering? boxes pose and answer good questions that students often ask. Some are designed to help students avoid common misconceptions; others provide analogies or alternate explanations of a concept; and still others address apparent inconsistencies in the material that the students are learning. These topics can be assigned or omitted at the instructor’s discretion.



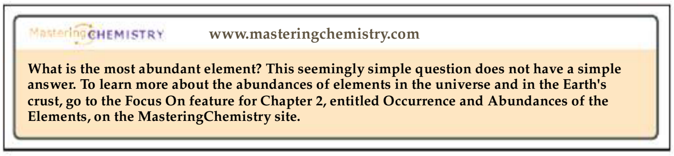
13-1 ARE YOU WONDERING...

What is the nature of the intermolecular forces in a mixture of carbon disulfide and acetone?

Carbon disulfide is a nonpolar molecule, and so in the pure substance the only intermolecular forces are weak London dispersion forces; carbon disulfide is a volatile liquid. Acetone is a polar molecule, and in the pure substance dipole–dipole forces are strong. Acetone is somewhat less volatile than carbon disulfide. In a solution of acetone in carbon disulfide (case 3 on page 564), the dipoles of acetone molecules polarize carbon disulfide molecules, giving rise to *dipole–induced dipole* interactions.

Focus On Discussions

References are given near the end of chapter to a **Focus On** essay which is found on the **Mastering-Chemistry**™ site (www.masteringchemistry.com). These essays describe interesting and significant applications of the chemistry discussed in the chapter. They help show the importance of chemistry in all aspects of daily life.



MasteringCHEMISTRY www.masteringchemistry.com

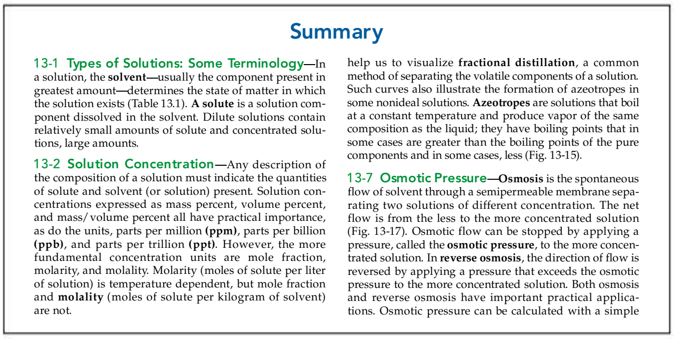
What is the most abundant element? This seemingly simple question does not have a simple answer. To learn more about the abundances of elements in the universe and in the Earth's crust, go to the Focus On feature for Chapter 2, entitled Occurrence and Abundances of the Elements, on the MasteringChemistry site.

Additional Material on Organic Chemistry Chapter

Chapter 27 includes references to discussions of Organic Acids and Bases; A Closer Look at the E2 Mechanism; and Carboxylic Acids and Their Derivatives: The Addition-Elimination Mechanism that are found on the MasteringChemistry™ site (www.masteringchemistry.com).

Summary

A prose **Summary** is provided for each chapter. The Summary is organized by the main headings in the chapter and incorporates the key terms in boldfaced type.



Summary

13-1 Types of Solutions: Some Terminology—In a solution, the **solvent**—usually the component present in greatest amount—determines the state of matter in which the solution exists (Table 13.1). **A solute** is a solution component dissolved in the solvent. Dilute solutions contain relatively small amounts of solute and concentrated solutions, large amounts.

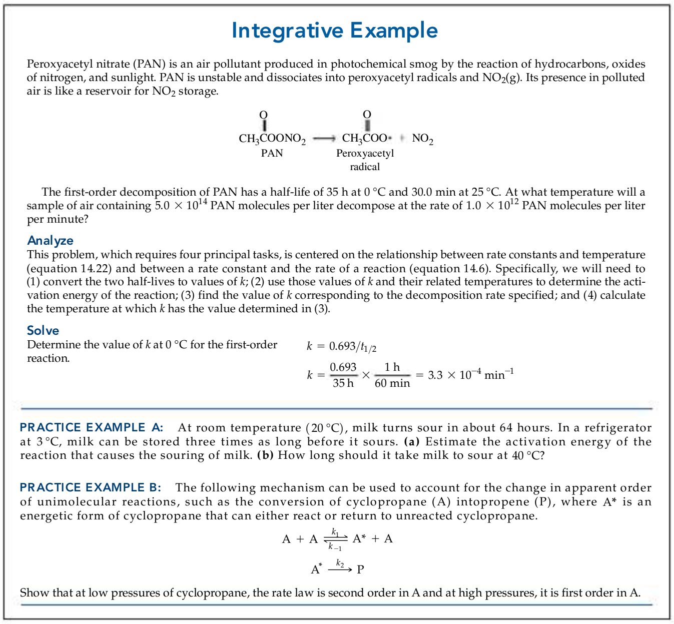
13-2 Solution Concentration—Any description of the composition of a solution must indicate the quantities of solute and solvent (or solution) present. Solution concentrations expressed as mass percent, volume percent, and mass/ volume percent all have practical importance, as do the units, parts per million **(ppm)**, parts per billion **(ppb)**, and parts per trillion **(ppt)**. However, the more fundamental concentration units are mole fraction, molarity, and molality. Molarity (moles of solute per liter of solution) is temperature dependent, but mole fraction and **molality** (moles of solute per kilogram of solvent) are not.

help us to visualize **fractional distillation**, a common method of separating the volatile components of a solution. Such curves also illustrate the formation of azeotropes in some nonideal solutions. **Azeotropes** are solutions that boil at a constant temperature and produce vapor of the same composition as the liquid; they have boiling points that in some cases are greater than the boiling points of the pure components and in some cases, less (Fig. 13-15).

13-7 Osmotic Pressure—**Osmosis** is the spontaneous flow of solvent through a semipermeable membrane separating two solutions of different concentration. The net flow is from the less to the more concentrated solution (Fig. 13-17). Osmotic flow can be stopped by applying a pressure, called the **osmotic pressure**, to the more concentrated solution. In **reverse osmosis**, the direction of flow is reversed by applying a pressure that exceeds the osmotic pressure to the more concentrated solution. Both osmosis and reverse osmosis have important practical applications. Osmotic pressure can be calculated with a simple

Integrative Example

An **Integrative Example** is provided near the end of chapter. These challenging examples show students how to link various concepts from the chapter and earlier chapters to solve complex problems. Each Integrative Example is now accompanied by a **Practice Example A** and **Practice Example B**. Answers to these Practice Examples are given on the **MasteringChemistry**™ site (www.masteringchemistry.com).



Integrative Example

Peroxyacetyl nitrate (PAN) is an air pollutant produced in photochemical smog by the reaction of hydrocarbons, oxides of nitrogen, and sunlight. PAN is unstable and dissociates into peroxyacetyl radicals and $NO_2(g)$. Its presence in polluted air is like a reservoir for NO_2 storage.

$$\underset{\text{PAN}}{CH_3\overset{O}{\overset{\|}{C}}OONO_2} \longrightarrow \underset{\substack{\text{Peroxyacetyl}\\ \text{radical}}}{CH_3\overset{O}{\overset{\|}{C}}OO\cdot} + NO_2$$

The first-order decomposition of PAN has a half-life of 35 h at 0 °C and 30.0 min at 25 °C. At what temperature will a sample of air containing 5.0×10^{14} PAN molecules per liter decompose at the rate of 1.0×10^{12} PAN molecules per liter per minute?

Analyze

This problem, which requires four principal tasks, is centered on the relationship between rate constants and temperature (equation 14.22) and between a rate constant and the rate of a reaction (equation 14.6). Specifically, we will need to (1) convert the two half-lives to values of *k*; (2) use those values of *k* and their related temperatures to determine the activation energy of the reaction; (3) find the value of *k* corresponding to the decomposition rate specified; and (4) calculate the temperature at which *k* has the value determined in (3).

Solve

Determine the value of *k* at 0 °C for the first-order reaction.

$$k = 0.693/t_{1/2}$$

$$k = \frac{0.693}{35\ \text{h}} \times \frac{1\ \text{h}}{60\ \text{min}} = 3.3 \times 10^{-4}\ \text{min}^{-1}$$

PRACTICE EXAMPLE A: At room temperature (20 °C), milk turns sour in about 64 hours. In a refrigerator at 3 °C, milk can be stored three times as long before it sours. **(a)** Estimate the activation energy of the reaction that causes the souring of milk. **(b)** How long should it take milk to sour at 40 °C?

PRACTICE EXAMPLE B: The following mechanism can be used to account for the change in apparent order of unimolecular reactions, such as the conversion of cyclopropane (A) intopropene (P), where A* is an energetic form of cyclopropane that can either react or return to unreacted cyclopropane.

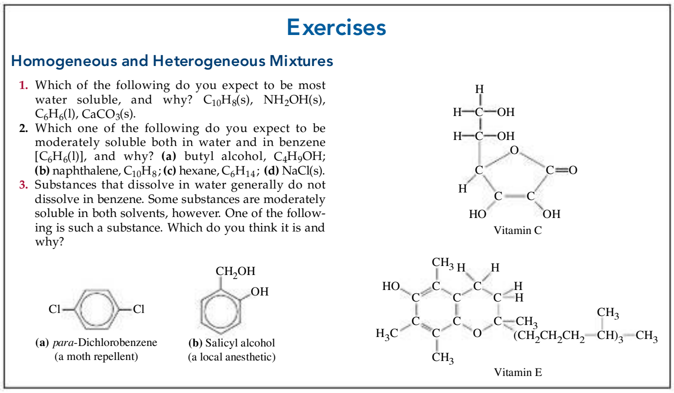
$$A + A \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} A^* + A$$

$$A^* \xrightarrow{k_2} P$$

Show that at low pressures of cyclopropane, the rate law is second order in A and at high pressures, it is first order in A.

End-of-Chapter Questions and Exercises

Each chapter ends with four categories of questions:



Exercises

Homogeneous and Heterogeneous Mixtures

1. Which of the following do you expect to be most water soluble, and why? $C_{10}H_8(s)$, $NH_2OH(s)$, $C_6H_6(l)$, $CaCO_3(s)$.
2. Which one of the following do you expect to be moderately soluble both in water and in benzene [$C_6H_6(l)$], and why? **(a)** butyl alcohol, C_4H_9OH; **(b)** naphthalene, $C_{10}H_8$; **(c)** hexane, C_6H_{14}; **(d)** $NaCl(s)$.
3. Substances that dissolve in water generally do not dissolve in benzene. Some substances are moderately soluble in both solvents, however. One of the following is such a substance. Which do you think it is and why?

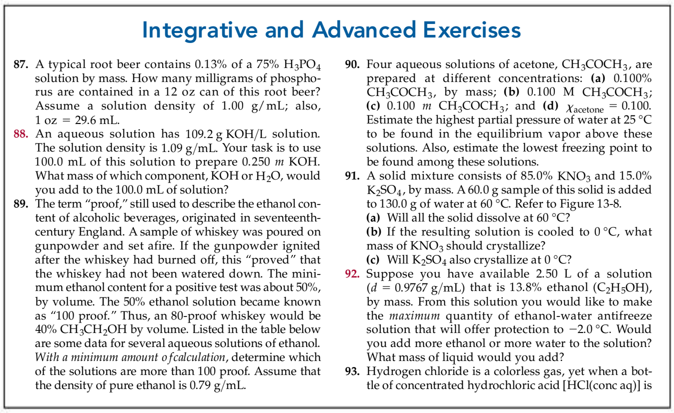
(a) *para*-Dichlorobenzene (a moth repellent)

(b) Salicyl alcohol (a local anesthetic)

Vitamin C

Vitamin E

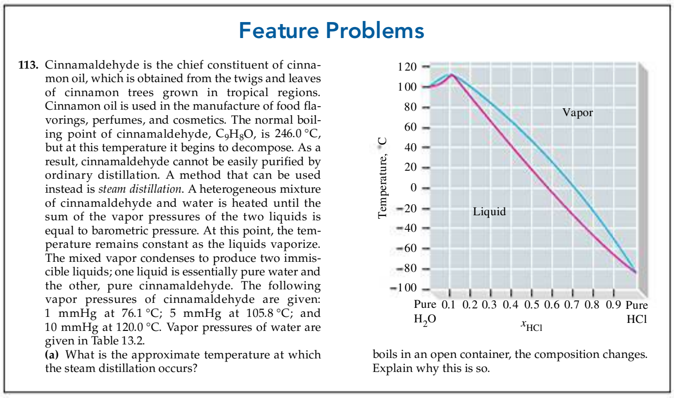
Exercises are organized by topic subheads and are presented in pairs. Answers to selected questions (i.e., those numbered in red) are given on the **MasteringChemistry**™ site (www.masteringchemistry.com).



Integrative and Advanced Exercises

87. A typical root beer contains 0.13% of a 75% H_3PO_4 solution by mass. How many milligrams of phosphorus are contained in a 12 oz can of this root beer? Assume a solution density of 1.00 g/mL; also, 1 oz = 29.6 mL.
88. An aqueous solution has 109.2 g KOH/L solution. The solution density is 1.09 g/mL. Your task is to use 100.0 mL of this solution to prepare 0.250 *m* KOH. What mass of which component, KOH or H_2O, would you add to the 100.0 mL of solution?
89. The term "proof," still used to describe the ethanol content of alcoholic beverages, originated in seventeenth-century England. A sample of whiskey was poured on gunpowder and set afire. If the gunpowder ignited after the whiskey had burned off, this "proved" that the whiskey had not been watered down. The minimum ethanol content for a positive test was about 50%, by volume. The 50% ethanol solution became known as "100 proof." Thus, an 80-proof whiskey would be 40% CH_3CH_2OH by volume. Listed in the table below are some data for several aqueous solutions of ethanol. *With a minimum amount ofcalculation*, determine which of the solutions are more than 100 proof. Assume that the density of pure ethanol is 0.79 g/mL.
90. Four aqueous solutions of acetone, CH_3COCH_3, are prepared at different concentrations: **(a)** 0.100% CH_3COCH_3, by mass; **(b)** 0.100 M CH_3COCH_3; **(c)** 0.100 *m* CH_3COCH_3; and **(d)** $\chi_{acetone} = 0.100$. Estimate the highest partial pressure of water at 25 °C to be found in the equilibrium vapor above these solutions. Also, estimate the lowest freezing point to be found among these solutions.
91. A solid mixture consists of 85.0% KNO_3 and 15.0% K_2SO_4, by mass. A 60.0 g sample of this solid is added to 130.0 g of water at 60 °C. Refer to Figure 13-8.
    (a) Will all the solid dissolve at 60 °C?
    (b) If the resulting solution is cooled to 0 °C, what mass of KNO_3 should crystallize?
    (c) Will K_2SO_4 also crystallize at 0 °C?
92. Suppose you have available 2.50 L of a solution ($d = 0.9767$ g/mL) that is 13.8% ethanol (C_2H_5OH), by mass. From this solution you would like to make the *maximum* quantity of ethanol-water antifreeze solution that will offer protection to −2.0 °C. Would you add more ethanol or more water to the solution? What mass of liquid would you add?
93. Hydrogen chloride is a colorless gas, yet when a bottle of concentrated hydrochloric acid [HCl(conc aq)] is

Integrative and Advanced Exercises are more advanced than the preceding *Exercises*. They are not grouped by topic or type. They integrate material from sections of the chapter and sometimes from multiple chapters. In some instances, they introduce new ideas or pursue specific ideas further than is done in the chapter. Answers to selected questions (i.e., those numbered in red) are given on the **MasteringChemistry**™ site (www.masteringchemistry.com).

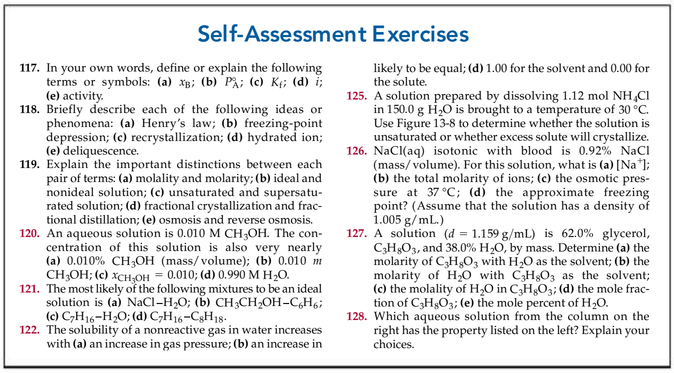


Feature Problems

113. Cinnamaldehyde is the chief constituent of cinnamon oil, which is obtained from the twigs and leaves of cinnamon trees grown in tropical regions. Cinnamon oil is used in the manufacture of food flavorings, perfumes, and cosmetics. The normal boiling point of cinnamaldehyde, C_9H_8O, is 246.0 °C, but at this temperature it begins to decompose. As a result, cinnamaldehyde cannot be easily purified by ordinary distillation. A method that can be used instead is *steam distillation*. A heterogeneous mixture of cinnamaldehyde and water is heated until the sum of the vapor pressures of the two liquids is equal to barometric pressure. At this point, the temperature remains constant as the liquids vaporize. The mixed vapor condenses to produce two immiscible liquids; one liquid is essentially pure water and the other, pure cinnamaldehyde. The following vapor pressures of cinnamaldehyde are given: 1 mmHg at 76.1 °C; 5 mmHg at 105.8 °C; and 10 mmHg at 120.0 °C. Vapor pressures of water are given in Table 13.2.
    (a) What is the approximate temperature at which the steam distillation occurs?

boils in an open container, the composition changes. Explain why this is so.

Feature Problems require the highest level of skill to solve. Some deal with classic experiments; some require students to interpret data or graphs; some suggest alternative techniques for problem solving; some are comprehensive in their scope; and some introduce new material. These problems are a resource that can be used in several ways: for discussion in class, for individually assigned homework, or for collaborative group work. Answers to selected questions (i.e., those numbered in red) are given on the **MasteringChemistry**™ site (www.masteringchemistry.com).



Self-Assessment Exercises

117. In your own words, define or explain the following terms or symbols: **(a)** x_B; **(b)** P°_A; **(c)** K_f; **(d)** i; **(e)** activity.
118. Briefly describe each of the following ideas or phenomena: **(a)** Henry's law; **(b)** freezing-point depression; **(c)** recrystallization; **(d)** hydrated ion; **(e)** deliquescence.
119. Explain the important distinctions between each pair of terms: **(a)** molality and molarity; **(b)** ideal and nonideal solution; **(c)** unsaturated and supersaturated solution; **(d)** fractional crystallization and fractional distillation; **(e)** osmosis and reverse osmosis.
120. An aqueous solution is 0.010 M CH_3OH. The concentration of this solution is also very nearly **(a)** 0.010% CH_3OH (mass/volume); **(b)** 0.010 *m* CH_3OH; **(c)** $x_{CH_3OH} = 0.010$; **(d)** 0.990 M H_2O.
121. The most likely of the following mixtures to be an ideal solution is **(a)** $NaCl-H_2O$; **(b)** $CH_3CH_2OH-C_6H_6$; **(c)** $C_7H_{16}-H_2O$; **(d)** $C_7H_{16}-C_8H_{18}$.
122. The solubility of a nonreactive gas in water increases with **(a)** an increase in gas pressure; **(b)** an increase in

likely to be equal; **(d)** 1.00 for the solvent and 0.00 for the solute.

125. A solution prepared by dissolving 1.12 mol NH_4Cl in 150.0 g H_2O is brought to a temperature of 30 °C. Use Figure 13-8 to determine whether the solution is unsaturated or whether excess solute will crystallize.
126. NaCl(aq) isotonic with blood is 0.92% NaCl (mass/volume). For this solution, what is **(a)** $[Na^+]$; **(b)** the total molarity of ions; **(c)** the osmotic pressure at 37 °C; **(d)** the approximate freezing point? (Assume that the solution has a density of 1.005 g/mL.)
127. A solution ($d = 1.159$ g/mL) is 62.0% glycerol, $C_3H_8O_3$, and 38.0% H_2O, by mass. Determine **(a)** the molarity of $C_3H_8O_3$ with H_2O as the solvent; **(b)** the molarity of H_2O with $C_3H_8O_3$ as the solvent; **(c)** the molality of H_2O in $C_3H_8O_3$; **(d)** the mole fraction of $C_3H_8O_3$; **(e)** the mole percent of H_2O.
128. Which aqueous solution from the column on the right has the property listed on the left? Explain your choices.

Self-Assessment Exercises are designed to help students review and prepare for some of the types of questions that often appear on quizzes and exams. Students can use these questions to decide whether they are ready to move on to the next chapter or first spend more time working with the concepts in the current chapter. Answers with explanations to selected questions (i.e., those numbered in red) are given on the **MasteringChemistry**™ site (www.mastering chemistry.com).

Appendices

Five Appendices at the back of the book provide important information:

Appendix A succinctly reviews of some basic **Mathematical Operations**.

Appendix B concisely describes some basic **Physical Concepts**.

Appendix C summarizes the conventions of **SI Units**.

Appendix D provides 5 useful **Data Tables**, including the new Table D.5 Isotopic Masses and Their Abundance.

Appendix E provides guidelines, along with an example, for constructing **Concept Maps**.

Appendix F consists of a **Glossary** of all the key terms in the book.

Appendix G provides **Answers to the Concept Assessment Questions**.

- For easy reference, the **Periodic Table** and a **Tabular Listing of Elements** are presented on the inside of the front cover.
- For convenience, listings of **Selected Physical Constants, Some Conversion Factors, Some Useful Geometric Formulas**, and **Locations of Important Data and Other Useful Information** are presented on the inside of the back cover.

SUPPLEMENTS

For the Instructor and the Student

- The **MasteringChemistry™ website** (http://www.masteringchemistry.com) is a comprehensive site that offers many learning and teaching tools. For instructor-assigned homework, MasteringChemistry™ provides the first adaptive-learning online tutorial and assessment system. Based on extensive research of precise concepts students struggle with, the system is able to coach students with feedback specific to their needs and with simpler problems upon request. The result is a large set of targeted tutorials that help optimize study time and maximize learning for students. In addition, the MasteringChemistry™ site also includes a Pearson eText. This robust eText platform enables students and instructors to highlight sections, add notes, share notes, and magnify any of the images or pages without distortion. The MasteringChemistry™ site also contains a Study Area which contains a new Self Quizzing feature for students and an electronic version of the Math Review Toolkit; students can access the content in the Study Area without instructor involvement.

For the Instructor

- An **Instructor's Resource CD-ROM** (978-013-509778-6) provides instructors with the following 10 supplements designed to facilitate lecture presentations, encourage class discussions, aid in creating tests, and foster learning:
    - An **Instructor's Resource Manual**, organized by chapter, provides detailed lecture outlines, describes some common student misconceptions, and demonstrates how to integrate the various instructor resources into the course.
    - The **Complete Solutions Manual** contains full solutions to all the end-of chapter exercises and problems (including those Self-Assessment Exercises that are not discussion questions), as well as full solutions to all the Practice Examples A and B in the book.
    - A **Testbank (Test Item File)** in Word provides more than 2700 questions. Many of the questions are in multiple-choice form, but there are also true/false and short-answer questions. Each question is accompanied by the correct answer, the relevant chapter section in the textbook, and a level of difficulty (i.e., 1 for Easy, 2 for Moderate, and 3 for Challenging).
    - The **Computerized Testbank (Pearson TestGen)** presents the testbank in a powerful program that enables instructors to view and edit

  existing questions, create new questions, and generate quizzes, tests, exams, or homework. TestGen also allows instructors to administer tests on a local area network, have the tests graded electronically, and have the results prepared in electronic or printed reports.
  - **PowerPoints Set 1** consists of all the figures and photos in the textbook in PowerPoint format.
  - **PowerPoints Set 2** provides lecture outlines for each chapter of the textbook.
  - **PowerPoints Set 3** provides questions for Personal Response Systems (i.e., clickers) that can be used to engage students in lectures and to obtain immediate feedback about their understanding of the concepts being presented.
  - **PowerPoints Set 4** consists of the all worked Examples from the textbook in PowerPoint format.
  - **Focus On Discussions** consist of all the Focus On Essays referenced in the textbook which students can find on the **MasteringChemistry**™ site (www.masteringchemistry.com).
  - **Additional Material on Organic Chemistry** consists of discussions of Organic Acids and Bases; A Closer Look at the E2 Mechanism; and Carboxylic Acids and Their Derivatives: The Addition-Elimination Mechanism that are referenced in Chapter 27. Students can find this material on the MasteringChemistry™ site (www.masteringchemistry.com).
  - **Answers to Practice Examples and to selected End-of-Chapter Exercises and Problems** (i.e., those numbered in red in the textbook) are provided here for the convenience of instructors. This same material is also available to students on the **MasteringChemistry**™ site (www.masteringchemistry.com).
- The **Complete Solutions Manual** is also available in printed form (978-013-504293-9). With instructor approval, arrangements can be made with the publisher to make this manual available to students.
- **Transparency Package** (978-013-703215-0) provides colour acetates of selected figures, tables, and photos from the textbook.
- A prebuilt **WebCT® Course** (978-013-703208-2) has been prepared to accompany the book.
- **Pearson's Technology Specialists** work with faculty and campus course designers to ensure that Pearson technology products, assessment tools, and online course materials are tailored to meet your specific needs. This highly qualified team is dedicated to helping students take full advantage of a wide range of educational resources, by assisting in the integration of a variety of instructional materials and media formats. Your local Pearson Education sales representative can provide you with more details about this service program.
- **The CourseSmart eTextbook** (978-013-509775-5) goes beyond traditional expectations—providing instant, online access to the textbooks and course materials you need at a lower cost for students. And even as students save money, you can save time and energy with a digital eTextbook that allows you to search for the most relevant content at the very moment you need it. Whether it's evaluating textbooks or creating lecture notes to help students with difficult concepts, CourseSmart can make life a little easier. See how when you visit www.coursesmart.com/ instructors.

For the Student

- Along with an **Access Code Card for Mastering Chemistry**™, each new copy of the book is accompanied by a 10-page **Study Card**

(978-013-703212-9). This card provides a convenient concise review of some of the key concepts and topics discussed in each chapter of the textbook.

- The **Selected Solutions Manual** (978-013-504292-2) provides full solutions to all the end-of chapter exercises and problems that are numbered in red.
- The **Math Review Toolkit** (978-013-612039-1) contains a review of the essential math skills required for each chapter of the textbook.
- **The CourseSmart eTextbook** (978-013-509775-5) goes beyond traditional expectations—providing instant, online access to the textbooks and course materials you need at an average savings of 50%. With instant access from any computer and the ability to search your text, you'll find the content you need quickly, no matter where you are. And with online tools like highlighting and note-taking, you can save time and study efficiently. See all the benefits at www.coursesmart.com/ students.

ACKNOWLEDGMENTS

We are grateful to the following instructors who provided formal reviews of parts of the manuscript.

Brian M. Baker *University of Notre Dame*
Robert J. Balahura *University of Guelph*
John Carran *Queen's University*
Chin Li Cheung *University of Nebraska, Lincoln*
Savitri Chandrasekhar *University of Toronto – Scarborough*
H. Floyd Davis *Cornell University*

From the clinic that treats "chemical dependency" to a theatrical performance with "good chemistry" to the food label stating "no chemicals added," chemistry and chemicals seem an integral part of life, even if everyday references to them are often misleading. A label implying the absence of chemicals in a food makes no sense. All foods consist entirely of chemicals, even if "organically grown." In fact, all material objects—whether living or inanimate—are made up only of chemicals, and we should begin our study with that thought clearly in mind.

By manipulating materials in their environment, people have always practiced chemistry. Among the earliest applications were the glazing of pottery, the smelting of ores to produce metals, the tanning of hides, the dyeing of fabrics, and the making of cheese, wine, beer, and soap. With modern knowledge, though, chemists can decompose matter into its smallest components (atoms) and reassemble those components into materials that do not exist naturally and that often exhibit unusual properties.

Thus, motor fuels and thousands of chemicals used in the manufacture of plastics, synthetic fabrics, pharmaceuticals, and pesticides can all be made from petroleum. Modern chemical knowledge is also needed to understand the processes that sustain life and to understand and control processes that are detrimental to the environment, such as the formation of smog and the destruction of stratospheric ozone. Because it relates to so many areas of human endeavor, chemistry is sometimes called the central science.

Early chemical knowledge consisted of the “how to” of chemistry, discovered through trial and error. Modern chemical knowledge answers the “why” as well as the “how to” of chemical change. It is grounded in principles and theory, and mastering the principles of chemistry requires a systematic approach to the subject. Scientific progress depends on the way scientists do their work—asking the right questions, designing the right experiments to supply the answers, and formulating plausible explanations of their findings. We begin with a closer look into the scientific method.

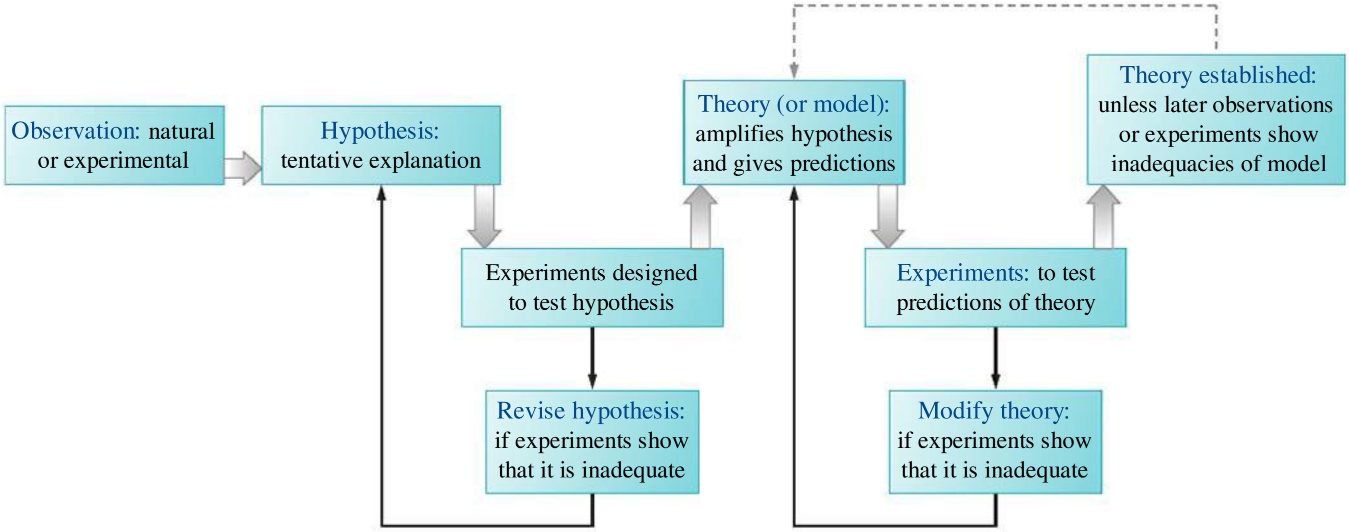
1-1 The Scientific Method

Science differs from other fields of study in the *method* that scientists use to acquire knowledge and the special significance of this knowledge. Scientific knowledge can be used to explain natural phenomena and, at times, to *predict* future events.

The ancient Greeks developed some powerful methods of acquiring knowledge, particularly in mathematics. The Greek approach was to start with certain basic assumptions, or premises. Then, by the method known as *deduction*, certain conclusions must logically follow. For example, if $a = b$ and $b = c$, then $a = c$. Deduction alone is not enough for obtaining scientific knowledge, however. The Greek philosopher Aristotle *assumed* four fundamental substances: air, earth, water, and fire. All other materials, he believed, were formed by combinations of these four elements. Chemists of several centuries ago (more commonly referred to as alchemists) tried, in vain, to apply the four-element idea to turn lead into gold. They failed for many reasons, one being that the four-element assumption is false.

The scientific method originated in the seventeenth century with such people as Galileo, Francis Bacon, Robert Boyle, and Isaac Newton. The key to the method is to make no initial assumptions, but rather to make careful observations of natural phenomena. When enough observations have been made so that a pattern begins to emerge, a generalization or natural law can be formulated describing the phenomenon. **Natural laws** are concise statements, often in mathematical form, about natural phenomena. The form of reasoning in which a general statement or natural law is inferred from a set of observations is called *induction*. For example, early in the sixteenth century, the Polish astronomer Nicolas Copernicus (1473–1543), through careful study of astronomical observations, concluded that Earth revolves around the sun in a circular orbit, although the general teaching of the time, not based on scientific study, was that the sun and other heavenly bodies revolved around Earth. We can think of Copernicus’s statement as a natural law. Another example of a natural law is the radioactive decay law, which dictates how long it takes for a radioactive substance to lose its radioactivity.

The success of a natural law depends on its ability to explain, or account for, observations and to predict new phenomena. Copernicus’s work was a great success because he was able to predict future positions of the planets more accurately than his contemporaries. We should not think of a natural law as an *absolute* truth, however. Future experiments may require us to modify the law. For example, Copernicus’s ideas were refined a half-century later by Johannes Kepler, who showed that planets travel in elliptical, not circular, orbits. To verify a natural law, a scientist designs *experiments* that show whether the conclusions deduced from the natural law are supported by experimental results.



Observation: natural or experimental
Hypothesis: tentative explanation
Experiments designed to test hypothesis
Revise hypothesis: if experiments show that it is inadequate
Theory (or model): amplifies hypothesis and gives predictions
Experiments: to test predictions of theory
Modify theory: if experiments show that it is inadequate
Theory established: unless later observations or experiments show inadequacies of model

▲ FIGURE 1-1
The scientific method illustrated

A **hypothesis** is a tentative explanation of a natural law. If a hypothesis survives testing by experiments, it is often referred to as a theory. In a broader sense, a **theory** is a model or way of looking at nature that can be used to explain natural laws and make further predictions about natural phenomena. When differing or conflicting theories are proposed, the one that is most successful in its predictions is generally chosen. Also, the theory that involves the smallest number of assumptions—the simplest theory—is preferred. Over time, as new evidence accumulates, most scientific theories undergo modification, and some are discarded.

The **scientific method** is the combination of observation, experimentation, and the formulation of laws, hypotheses, and theories. The method is illustrated by the flow diagram in Figure 1-1. Scientists may develop a pattern of thinking about their field, known as a *paradigm*. Some paradigms may be successful at first but then become less so. When that happens, a new paradigm may be needed or, as is sometimes said, a "paradigm shift" occurs. In a way, the method of inquiry that we call the scientific method is itself a paradigm, and some people feel that it, too, is in need of change. That is, the varied activities of modern scientists are more complex than the simplified description of the scientific method presented here.* In any case, merely following a set of procedures, rather like using a cookbook, will not guarantee scientific success.

Another factor in scientific discovery is chance, or serendipity. Many discoveries have been made by accident. For example, in 1839, the American inventor Charles Goodyear was searching for a treatment for natural rubber that would make it less brittle when cold and less tacky when warm. In the course of this work, he accidentally spilled a rubber–sulfur mixture on a hot stove and found that the resulting product had exactly the properties he was seeking. Other chance discoveries include X-rays, radioactivity, and penicillin. So scientists and inventors always need to be alert to unexpected observations. Perhaps no one was more aware of this than Louis Pasteur, who wrote, "Chance favors the prepared mind."

1-2 Properties of Matter

Dictionary definitions of chemistry usually include the terms *matter*, *composition*, and *properties*, as in the statement that "chemistry is the science that deals with the composition and properties of matter." In this and the next section, we will consider some basic ideas relating to these three terms in hopes of gaining a better understanding of what chemistry is all about.

Matter is anything that occupies space and displays the properties of *mass* and inertia. Every human being is a collection of matter. We all occupy space, and we describe our mass in terms of weight, a related property. (Mass and weight are described in more detail in Section 1-4. Inertia is described in Appendix B.) All the objects that we see around us consist of matter. The gases of the atmosphere, even though they are invisible, are matter—they occupy space and have mass. Sunlight is *not* matter; rather, it is a form of energy. Energy is discussed in later chapters.

Composition refers to the parts or components of a sample of matter and their relative proportions. Ordinary water is made up of two simpler substances—hydrogen and oxygen—present in certain fixed proportions. A chemist would say that the composition of water is 11.19% hydrogen and 88.81% oxygen by mass. Hydrogen peroxide, a substance used in bleaches and antiseptics, is also made up of hydrogen and oxygen, but it has a different composition. Hydrogen peroxide is 5.93% hydrogen and 94.07% oxygen by mass.

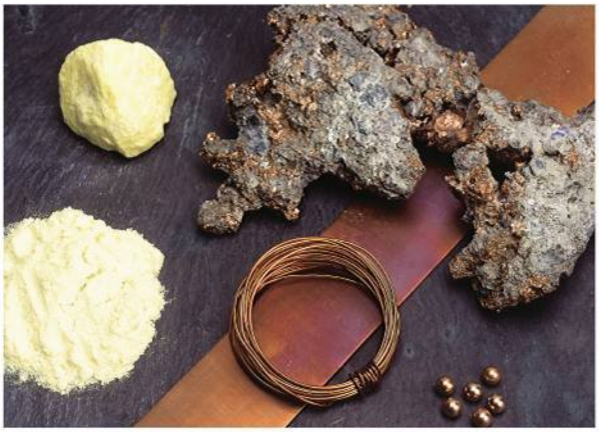
Properties are those qualities or attributes that we can use to distinguish one sample of matter from others; and, as we consider next, the properties of matter are generally grouped into two broad categories: physical and chemical.

Physical Properties and Physical Changes

A **physical property** is one that a sample of matter displays without changing its composition. Thus, we can distinguish between the reddish brown solid, copper, and the yellow solid, sulfur, by the physical property of *color* (Fig. 1-2).

Another physical property of copper is that it can be hammered into a thin sheet of foil (see Figure 1-2). Solids having this ability are said to be *malleable*. Sulfur is not malleable. If we strike a chunk of sulfur with a hammer, it crumbles into a powder. Sulfur is *brittle*. Another physical property of copper that sulfur does not share is the ability to be drawn into a fine wire (ductility). Also, sulfur is a far poorer conductor of heat and electricity than is copper.

Sometimes a sample of matter undergoes a change in its physical appearance. In such a **physical change**, some of the physical properties of the sample may change, but its composition remains unchanged. When liquid water freezes into solid water (ice), it certainly looks different and, in many ways, it is different. Yet, the water remains 11.19% hydrogen and 88.81% oxygen by mass.

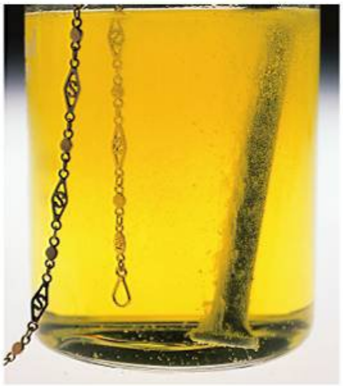


▶ FIGURE 1-2
Physical properties of sulfur and copper
A lump of sulfur (left) crumbles into a yellow powder when hammered. Copper (right) can be obtained as large lumps of native copper, formed into pellets, hammered into a thin foil, or drawn into a wire.

Chemical Properties and Chemical Changes

In a **chemical change**, or **chemical reaction**, one or more kinds of matter are converted to new kinds of matter with different compositions. The key to identifying chemical change, then, comes in observing a *change in composition*. The burning of paper involves a chemical change. Paper is a complex material, but its principal constituents are carbon, hydrogen, and oxygen. The chief products of the combustion are two gases, one consisting of carbon and oxygen (carbon dioxide) and the other consisting of hydrogen and oxygen (water, as steam). The ability of paper to burn is an example of a chemical property. A **chemical property** is the ability (or inability) of a sample of matter to undergo a change in composition under stated conditions.

Zinc reacts with hydrochloric acid solution to produce hydrogen gas and a solution of zinc chloride in water (Fig. 1-3). This reaction is one of zinc's distinctive chemical properties, just as the inability of gold to react with hydrochloric acid is one of gold's chemical properties. Sodium reacts not only with hydrochloric acid but also with water. In some of their physical properties, zinc, gold, and sodium are similar. For example, each is malleable and a good conductor of heat and electricity. In most of their chemical properties, though, zinc, gold, and sodium are quite different. Knowing these differences helps us to understand why zinc, which does not react with water, is used in roofing nails, roof flashings, and rain gutters, and sodium is not. Also, we can appreciate why gold, because of its chemical inertness, is prized for jewelry and coins: It does not tarnish or rust. In our study of chemistry, we will see why substances differ in properties and how these differences determine the ways in which we use them.



▲ FIGURE 1-3
A chemical property of zinc and gold: reaction with hydrochloric acid
The zinc-plated (galvanized) nail reacts with hydrochloric acid, producing the bubbles of hydrogen gas seen on its surface. The gold bracelet is unaffected by hydrochloric acid. In this photograph, the zinc plating has been consumed, exposing the underlying iron nail. The reaction of iron with hydrochloric acid imparts some color to the acid solution.

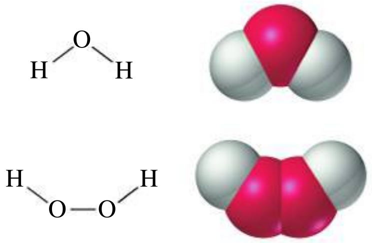
1-3 Classification of Matter

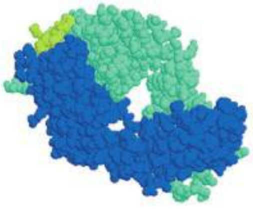
Matter is made up of very tiny units called **atoms**. Each different type of atom is the building block of a different chemical **element**. Presently, the International Union of Pure and Applied Chemistry (IUPAC) recognizes 112 elements, and *all* matter is made up of just these types! The known elements range from common substances, such as carbon, iron, and silver, to uncommon ones, such as lutetium and thulium. About 90 of the elements can be obtained from natural sources. The remainder do not occur naturally and have been created only in laboratories. On the inside front cover you will find a complete listing of the elements and also a special tabular arrangement of the elements known as the *periodic table*. The periodic table is the chemist's directory of the elements. We will describe it in Chapter 2 and use it throughout most of the text.

◀ The International Union of Pure and Applied Chemistry (IUPAC) is recognized as the world authority on chemical nomenclature, terminology, standardized methods for measurement, atomic mass, and more. Along with many other activities, IUPAC publishes journals, technical reports, and chemical databases, most of which are available at www.iupac.org.

◀ The identity of an atom is established by a feature called its atomic number (see Section 2-3). Recent report of other new elements, such as elements 113 to 116 and 118, await confirmation. Characterizing "superheavy" elements is a daunting challenge; they are produced only a few atoms at a time and the atoms disintegrate almost instantaneously.

Chemical **compounds** are substances comprising atoms of two or more elements joined together. Scientists have identified millions of different chemical compounds. In some cases, we can isolate a molecule of a compound. A **molecule** is the smallest entity having the same proportions of the constituent atoms as does the compound as a whole. A molecule of water consists of three atoms: two hydrogen atoms joined to a single oxygen atom. A molecule of hydrogen peroxide has two hydrogen atoms and two oxygen atoms; the two oxygen atoms are joined together and one hydrogen atom is attached to each oxygen atom. By contrast, a molecule of the blood protein gamma globulin is made up of 19,996 atoms, but they are of just four types: carbon, hydrogen, oxygen, and nitrogen.

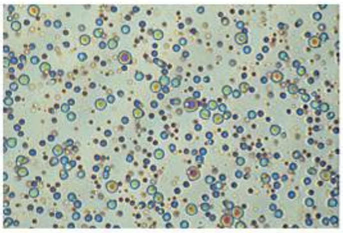




Gamma globulin

The composition and properties of an element or a compound are uniform throughout a given sample and from one sample to another. Elements and compounds are called **substances**. (In the chemical sense, the term *substance* should be used only for elements and compounds.) A *mixture* of substances can vary in composition and properties from one sample to another. One that is uniform in composition and properties throughout is said to be a **homogeneous mixture** or a *solution*. A given solution of sucrose (cane sugar) in water is uniformly sweet throughout the solution, but the sweetness of another sucrose solution may be rather different if the sugar and water are present in different proportions. Ordinary air is a homogeneous mixture of several gases, principally the *elements* nitrogen and oxygen. Seawater is a solution of the *compounds* water, sodium chloride (salt), and a host of others. Gasoline is a homogeneous mixture or solution of dozens of compounds.

In **heterogeneous mixtures**—sand and water, for example—the components separate into distinct regions. Thus, the composition and physical properties vary from one part of the mixture to another. Salad dressing, a slab of concrete, and the leaf of a plant are all heterogeneous. It is usually easy to distinguish heterogeneous from homogeneous mixtures. A scheme for classifying matter into elements and compounds and homogeneous and heterogeneous mixtures is summarized in Figure 1-4.



▲ Is it homogeneous or heterogeneous? When viewed through a microscope, homogenized milk is seen to consist of globules of fat dispersed in a watery medium. Homogenized milk is a *heterogeneous* mixture.

▶ It is composition, particularly its variability, that helps us distinguish the several classifications of matter.

▶ Solutions can be gaseous and liquids as described here, but they can also be solids. Some alloys are examples of solid solutions.

Separating Mixtures

A mixture can be separated into its components by appropriate physical means. Consider again the heterogeneous mixture of sand in water. When we pour this mixture into a funnel lined with porous filter paper, the water passes through and sand is retained on the paper. This process of separating a solid from the liquid in which it is suspended is called *filtration* (Fig. 1-5a). You will probably use this procedure in the laboratory. Conversely, we cannot separate a homogeneous mixture (solution) of copper(II) sulfate in water by filtration because all components pass through the paper. We can, however, boil the solution of copper(II) sulfate and water. In the process of *distillation*, a pure liquid is condensed from the vapor given off by a boiling solution. When all

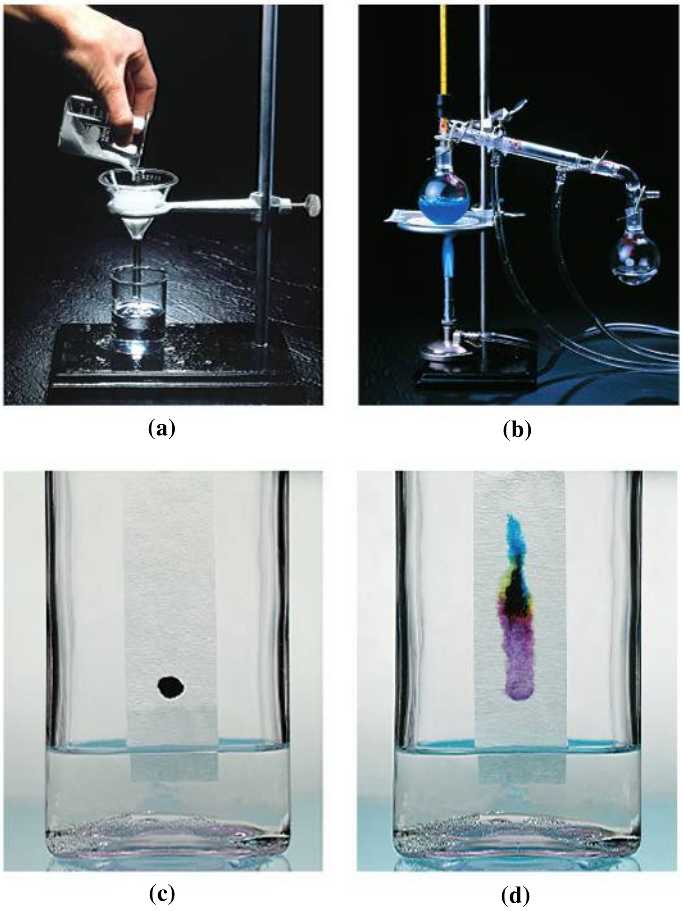
▲ FIGURE 1-4
A classification scheme for matter
Every sample of matter is either a single substance (an element or compound) or a mixture of substances. At the molecular level, an element consists of atoms of a single type and a compound consists of two or more different types of atoms, usually joined into molecules. In a homogeneous mixture, atoms or molecules are randomly mixed at the molecular level. In heterogeneous mixtures, the components are physically separated, as in a layer of octane molecules (a constituent of gasoline) floating on a layer of water molecules.



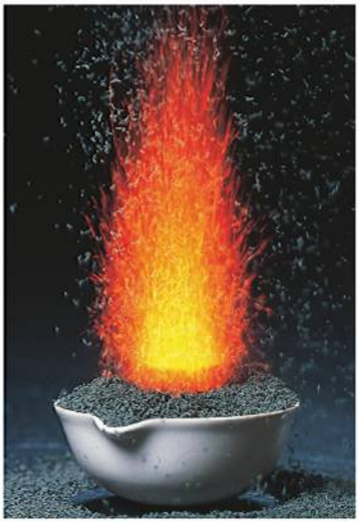
◀ FIGURE 1-5
Separating mixtures: a physical process
(a) Separation of a heterogeneous mixture by filtration: Solid copper(II) sulfate is retained on the filter paper, while liquid hexane passes through. **(b)** Separation of a homogeneous mixture by distillation: Copper(II) sulfate remains in the flask on the left as water passes to the flask on the right, by first evaporating and then condensing back to a liquid. **(c)** Separation of the components of ink using chromatography: A dark spot of black ink can be seen just above the water line as water moves up the paper. **(d)** Water has dissolved the colored components of the ink, and these components are retained in different regions on the paper according to their differing tendencies to adhere to the paper.

the water has been removed by boiling a solution of copper(II) sulfate in water, solid copper(II) sulfate remains behind (Fig. 1-5b).

Another method of separation available to modern chemists depends on the differing abilities of compounds to adhere to the surfaces of various solid substances, such as paper and starch. The technique of *chromatography* relies on this principle. The dramatic results that can be obtained with chromatography are illustrated by the separation of ink on a filter paper (Fig. 1-5c–d).

Decomposing Compounds

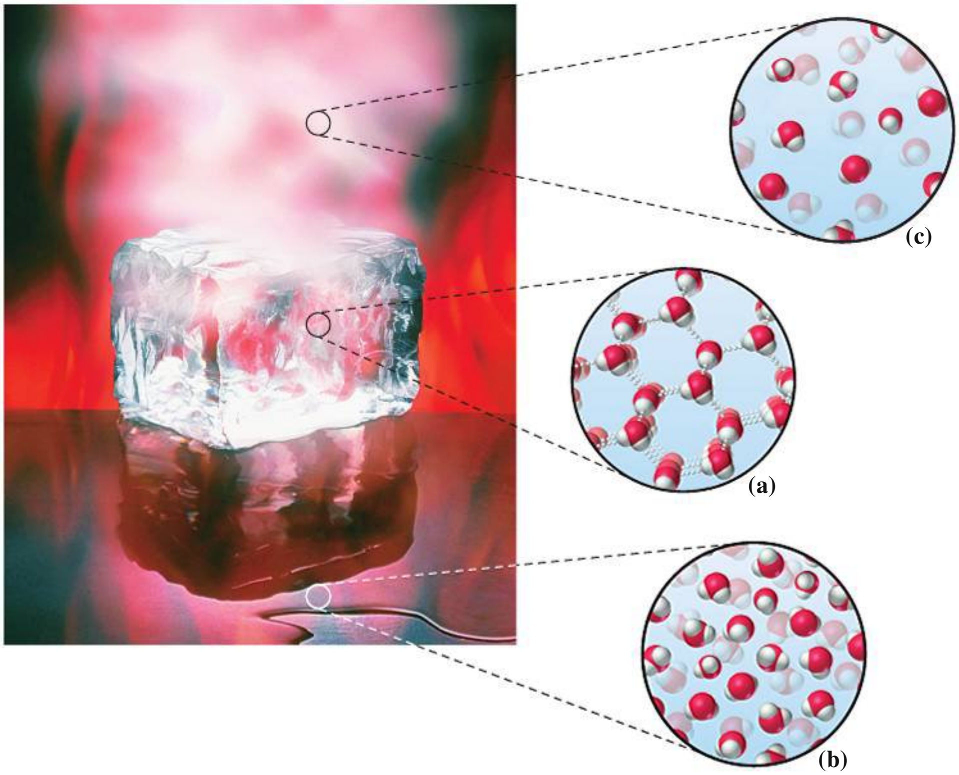
A chemical compound retains its identity during physical changes, but it can be decomposed into its constituent elements by *chemical changes*. The decomposition of compounds into their constituent elements is a more difficult matter than the mere physical separation of mixtures. The extraction of iron from iron oxide ores requires a blast furnace. The industrial production of pure magnesium from magnesium chloride requires electricity. It is generally easier to convert a compound into other compounds by a chemical reaction than it is to separate a compound into its constituent elements. For example, when heated, ammonium dichromate decomposes into the substances chromium(III) oxide, nitrogen, and water. This reaction, once used in movies to simulate a volcano, is illustrated in Figure 1-6.



▲ FIGURE 1-6
A chemical change: decomposition of ammonium dichromate

States of Matter

Matter is generally found in one of three *states*: solid, liquid, or gas. In a **solid**, atoms or molecules are in close contact, sometimes in a highly organized arrangement called a *crystal*. A solid has a definite shape. In a **liquid**, the atoms or molecules are usually separated by somewhat greater distances than in a solid. Movement of these atoms or molecules gives a liquid its most distinctive property—the ability to flow, covering the bottom and assuming the shape of its container. In a **gas**, distances between atoms or molecules are much greater



▶ FIGURE 1-7
Macroscopic and microscopic views of matter
The picture shows a block of ice on a heated surface and the three states of water. The circular insets show how chemists conceive of these states microscopically, in terms of molecules with two hydrogen atoms joined to one of oxygen. In ice **(a)**, the molecules are arranged in a regular pattern in a rigid framework. In liquid water **(b)**, the molecules are rather closely packed but move freely. In gaseous water **(c)**, the molecules are widely separated.

than in a liquid. A gas always expands to fill its container. Depending on conditions, a substance may exist in only one state of matter, or it may be present in two or three states. Thus, as the ice in a small pond begins to melt in the spring, water is in two states: solid and liquid (actually, three states if we also consider water vapor in the air above the pond). The three states of water are illustrated at two levels in Figure 1-7.

The *macroscopic level* refers to how we perceive matter with our eyes, through the outward appearance of objects. The *microscopic level* describes matter as chemists conceive of it—in terms of atoms and molecules and their behavior. In this text, we will describe many macroscopic, observable properties of matter, but to explain these properties, we will often shift our view to the atomic or molecular level—the microscopic level.

1-4 Measurement of Matter: SI (Metric) Units

▶ Nonnumerical information is *qualitative*, such as the color blue.

Chemistry is a *quantitative* science, which means that in many cases we can measure a property of a substance and compare it with a standard having a known value of the property. We express the measurement as the product of a *number* and a *unit*. The unit indicates the standard against which the measured quantity is being compared. When we say that the length of the playing field in football is 100 yd, we mean that the field is 100 times longer than a standard of length called the yard (yd). In this section, we will introduce some basic units of measurement that are important to chemists.

▶ The *definition of the meter*, formerly based on the atomic spectrum of ^{86}Kr, was changed to the speed of light in 1983. Effectively, the speed of light is now defined as 2.99792458×10^8 m/s.

The scientific system of measurement is called the *Système Internationale d'Unités* (International System of Units) and is abbreviated **SI**. It is a modern version of the metric system, a system based on the unit of length called a *meter* (m). The meter was originally defined as 1/10,000,000 of the distance from the equator to the North Pole and translated into the length of a metal bar kept in Paris. Unfortunately, this length is subject to change with temperature, and it cannot be exactly reproduced. The SI system substitutes for the standard meter bar an unchanging, reproducible quantity: 1 meter is the distance traveled by light in a vacuum in 1/299,792,458 of a second. Length is one of the seven

TABLE 1.1 SI Base Quantities

Physical Quantity	Unit	Symbol
Length	meter[a]	m
Mass	kilogram	kg
Time	second	s
Temperature	kelvin	K
Amount of substance[b]	mole	mol
Electric current[c]	ampere	A
Luminous intensity[d]	candela	cd

[a] The official spelling of this unit is "metre," but we will use the American spelling.
[b] The mole is introduced in Section 2-7.
[c] Electric current is described in Appendix B and in Chapter 20.
[d] Luminous intensity is not discussed in this text.

[a] The Greek letter μ (pronounced "mew").

fundamental quantities in the SI system (see Table 1.1). All other physical quantities have units that can be derived from these seven. SI is a *decimal* system. Quantities differing from the base unit by powers of ten are noted by the use of prefixes. For example, the prefix *kilo* means *one thousand* (10^3) times the base unit; it is abbreviated as k. Thus 1 *kilo*meter = 1000 meters, or 1 km = 1000 m. The SI prefixes are listed in Table 1.2.

Most measurements in chemistry are made in SI units. Sometimes we must convert between SI units, as when converting kilometers to meters. At other times we must convert measurements expressed in non-SI units into SI units, or from SI units into non-SI units. In all of these cases we can use a *conversion factor* or a series of conversion factors in a scheme called a conversion pathway. Later in this chapter, we will apply conversion pathways in a method of problem solving known as *dimensional analysis*. The method itself is described in some detail in Appendix A.

◀ It is a good idea to *memorize the most common SI prefixes* (such as G, M, k, d, c, m, μ, n, and p) because you can't survive in a world of science without knowing the SI prefixes.

Mass

Mass describes the quantity of matter in an object. In SI the standard of mass is 1 *kilogram* (kg), which is a fairly large unit for most applications in chemistry. More commonly we use the unit *gram* (g) (about the mass of three aspirin tablets).

Weight is the force of gravity on an object. It is directly proportional to mass, as shown in the following mathematical expressions.

$$W \propto m \text{ and } W = g \times m \tag{1.1}$$

◀ The symbol $\propto$ means "proportional to." It can be replaced by an equality sign and a proportionality constant. In expression (1.1), the constant is the acceleration due to gravity, g. (See Appendix B.)

An object has a fixed mass (m), which is independent of where or how the mass is measured. Its weight (W), however, may vary because the acceleration due to gravity (g) varies slightly from one point on Earth to another. Thus, an object that weighs 100.0 kg in St. Petersburg, Russia, weighs only 99.6 kg in Panama (about 0.4% less). The same object would weigh only about 17 kg on the moon. Although the weight of an object varies from place to place, its mass is the same in all locations. The terms *weight* and *mass* are often used interchangeably, but only mass is a measure of the quantity of matter. A common laboratory device for measuring mass is called a balance. A balance is often called, incorrectly, a scale.

The principle used in a balance is that of counteracting the force of gravity on an unknown mass with a force of equal magnitude that can be precisely measured. In older two-pan beam balances, the object whose mass is being determined is placed on one pan and counterbalancing is achieved through the force of gravity acting on *weights*, objects of precisely known mass, placed on the other pan. In the type of balance most commonly seen in laboratories today—the electronic balance—the counterbalancing force is a magnetic force produced by passing an electric current through an electromagnet. First, an initial balance condition is achieved when no object is present on the balance pan. When the object to be weighed is placed on the pan, the initial balance condition is upset. To restore the balance condition, additional electric current must be passed through the electromagnet. The magnitude of this additional current is proportional to the mass of the object being weighed and is translated into a mass reading that is displayed on the balance. An electronic balance is shown in the margin.

1-2 CONCEPT ASSESSMENT

Would either the two-pan beam balance or the electronic balance yield the same result for the mass of an object measured on the moon as that measured for the same object on Earth? Explain.

Time

In daily use we measure time in seconds, minutes, hours, and years, depending on whether we are dealing with short intervals (such as the time for a 100 m race) or long ones (such as the time before the next appearance of Halley's comet in 2062). We can use all these units in scientific work also, although in SI the standard of time is the *second* (s). A time interval of 1 second is not easily established. At one time it was based on the length of a day, but this is not constant because the rate of Earth's rotation undergoes slight variations. In 1956, the second was defined as 1/31,556,925.9747 of the length of the year 1900. With the advent of atomic clocks, a more precise definition became possible. The second is now defined as the duration of 9,192,631,770 cycles of a particular radiation emitted by certain atoms of the element cesium (cesium-133).

▶ Electromagnetic radiation is discussed in Section 8-1.

Temperature

To establish a temperature scale, we arbitrarily set certain fixed points and temperature increments called degrees. Two commonly used fixed points are the temperature at which ice melts and the temperature at which water boils, both at standard atmospheric pressure.*

On the **Celsius** scale, the melting point of ice is 0 °C, the boiling point of water is 100 °C, and the interval between is divided into 100 equal parts called Celsius degrees. On the **Fahrenheit** temperature scale, the melting point of ice is 32 °F, the boiling point of water is 212 °F, and the interval between is divided into 180 equal parts called Fahrenheit degrees. Figure 1-8 compares the Fahrenheit and Celsius temperature scales.

The SI temperature scale, called the **Kelvin** scale, assigns a value of zero to the lowest possible temperature. The zero on the Kelvin scale is denoted 0 K and it comes at –273.15 °C. We will discuss the Kelvin temperature scale in detail in Chapter 6. For now, it is enough to know the following:

- The interval on the Kelvin scale, called a *kelvin*, is the same size as the Celsius degree.
- When writing a Kelvin temperature, we do not use a degree symbol. That is, we write 0 K or 300 K, not 0 °K or 300 °K.
- The Kelvin scale is an absolute temperature scale; there are no negative Kelvin temperatures.

▶ The SI symbol for Kelvin temperature is T and that for Celsius temperature is t but shown here as t(°C). The Fahrenheit temperature, shown here as t(°F), is not recognized in SI.

In the laboratory, temperature is most commonly measured in Celsius degrees; however, these temperatures must often be converted to the Kelvin scale (in describing the behavior of gases, for example). Occasionally, particularly in some engineering applications, temperatures must be converted

between the Celsius and Fahrenheit scales. Temperature conversions can be made in a straightforward way by using the algebraic equations shown below.

$$\text{Kelvin from Celsius} \quad T(\text{K}) = t(^\circ\text{C}) + 273.15$$

$$\text{Fahrenheit from Celsius} \quad t(^\circ\text{F}) = \frac{9}{5}t(^\circ\text{C}) + 32$$

$$\text{Celsius from Fahrenheit} \quad t(^\circ\text{C}) = \frac{5}{9}[t(^\circ\text{F}) - 32]$$

The factors $\frac{9}{5}$ and $\frac{5}{9}$ arise because the Celsius scale uses 100 degrees between the two chosen reference points and the Fahrenheit scale uses 180 degrees: $180/100 = \frac{9}{5}$ and $100/180 = \frac{5}{9}$. The diagram in Figure 1-8 illustrates the relationship among the three scales for several temperatures.

EXAMPLE 1-1 Converting Between Fahrenheit and Celsius Temperatures

The predicted high temperature for New Delhi on a given day is 41 °C. Is this temperature higher or lower than the predicted daytime high of 103 °F for the same day in Phoenix, Arizona, reported by a newscaster?

Analyze

We are given a Celsius temperature and seek a comparison with a Fahrenheit temperature. To convert the given Celsius temperature to a Fahrenheit temperature, we use the equation given previously that expresses $t(^\circ\text{F})$ as a function of $t(^\circ\text{C})$.

Solve

$$t(^\circ\text{F}) = \frac{9}{5}t(^\circ\text{C}) + 32 = \frac{9}{5}(41) + 32 = 106\ ^\circ\text{F}$$

The predicted temperature for New Delhi, 106 °F, is 3 °F higher than for Phoenix, 103 °F.

(continued)

Assess

For temperatures at which $t(^\circ\text{C}) > -40\ ^\circ\text{C}$, the Fahrenheit temperature is greater than the Celsius temperature. If the Celsius temperature is lower than $-40\ ^\circ\text{C}$, then $t(^\circ\text{F})$ is lower than (more negative than) $t(^\circ\text{C})$ (Fig. 1-8). Concept Assessment 1-3 asks you to think further about the relationship between $t(^\circ\text{C})$ and $t(^\circ\text{F})$.

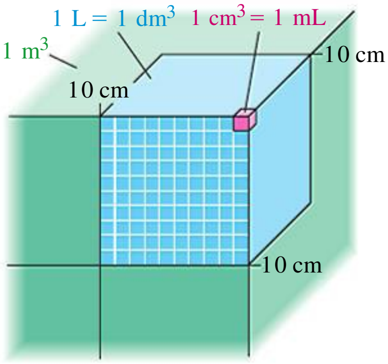
PRACTICE EXAMPLE A: A recipe in an American cookbook calls for roasting a cut of meat at 350 °F. What is this temperature on the Celsius scale?

PRACTICE EXAMPLE B: A particular automobile engine coolant has antifreeze protection to a temperature of $-22\ ^\circ\text{C}$. Will this coolant offer protection at temperatures as low as $-15\ ^\circ\text{F}$?

Answers to Practice Examples are given on the Mastering Chemistry site: www.masteringchemistry.com.

1-3 CONCEPT ASSESSMENT

Can there be a temperature at which °C and °F have the same value? Can there be more than one such temperature? Explain.



▲ FIGURE 1-9
Some metric volume units compared
The largest volume, shown in part, is the SI standard of 1 cubic meter (m^3). A cube with a length of 10 cm (1 dm) on edge (in blue) has a volume of 1000 cm^3 (1 dm^3) and is called 1 liter (1 L). The smallest cube is 1 cm on edge (red) and has a volume of 1 cm^3 = 1 mL.

▶ The official spelling is *litre*, but we will use the American spelling, *liter*.

Derived Units

The seven units listed in Table 1.1 are the SI units for the fundamental quantities of length, mass, time, and so on. Many measured properties are expressed as combinations of these fundamental, or base, quantities. We refer to the units of such properties as *derived units*. For example, velocity is a distance divided by the time required to travel that distance. The unit of velocity is length divided by time, such as m/s or $m\ s^{-1}$. Some derived units have special names. For example, the combination $kg\ m^{-1}\ s^{-2}$ is called the *pascal* (Chapter 6) and the combination $kg\ m^2\ s^{-2}$ is called the *joule* (Chapter 7). Other examples are given in Appendix C.

An important measurement that uses derived units is *volume*. Volume has the unit $(\text{length})^3$, and the SI standard unit of volume is the *cubic meter* (m^3). More commonly used volume units are the *cubic centimeter* (cm^3) and the *liter* (L). One liter is defined as a volume of 1000 cm^3, which means that one *milliliter* (1 mL) is equal to 1 cm^3. The liter is also equal to one *cubic decimeter* (1 dm^3). Several volume units are depicted in Figure 1-9.

Non-SI Units

Although its citizens are growing more accustomed to expressing distances in kilometers and volumes in liters, the United States is one of the few countries where most units used in everyday life are still non-SI. Masses are given in pounds, room dimensions in feet, and so on. In this book, we will not routinely use these non-SI units, but we will occasionally introduce them in examples and end-of-chapter exercises. In such cases, any necessary relationships between non-SI and SI units will be given or can be found on the inside back cover.

1-1 ARE YOU WONDERING...

Why attaching the units to a number is so important?

In 1993, NASA started the Mars Surveyor program to conduct an ongoing series of missions to explore Mars. In 1995, two missions were scheduled that would be launched in late 1998 and early 1999. The missions were the Mars Climate Orbiter (MCO) and the Mars Polar Lander (MPL). The MCO was launched December 11, 1998, and the MPL, January 3, 1999.

Nine and a half months after launch, the MCO was to fire its main engine to achieve an elliptical orbit around Mars. The MCO engine start occurred on September 23, 1999, but the MCO mission was lost when the orbiter entered the Martian atmosphere on a lower-than-expected trajectory. The MCO entered the low orbit because the computer on Earth used British Engineering units, whereas the MCO computer used SI units.

This error in units brought the MCO 56 km above the surface of Mars instead of the desired 250 km. At 250 km, the MCO would have successfully entered the desired elliptical orbit, and the $168 million orbiter would probably not have been lost.

◀ The development of science requires careful *quantitative measurement*. Theories have stood or fallen based on their agreement or otherwise with experiments in the fourth significant figure or beyond. Problem solving, the handling of units, and the use of significant figures (Section 1-7) are important in all areas of science.

1-5 Density and Percent Composition: Their Use in Problem Solving

Throughout this text, we will encounter new concepts about the structure and behavior of matter. One means of firming up our understanding of these new concepts is to work problems that relate concepts that we already know to those we are trying to understand. In this section, we will introduce two quantities frequently required in problem solving: density and percent composition.

Density

Here is an old riddle: "What weighs more, a ton of bricks or a ton of cotton?" If you answer that they weigh the same, you demonstrate a clear understanding of the meaning of weight and, indirectly, of the quantity of matter to which weight is proportional, that is, mass. Anyone who answers that the bricks weigh more than the cotton has confused the concepts of weight and density. Matter in a brick is more concentrated than in cotton—that is, the matter in a brick is confined to a smaller volume. Bricks are more dense than cotton. **Density** is the ratio of mass to volume.

$$\text{density } (d) = \frac{\text{mass } (m)}{\text{volume } (V)} \qquad \textbf{(1.2)}$$

Mass and volume are both extensive properties. An **extensive property** is *dependent* on the quantity of matter observed. However, if we divide the mass of a substance by its volume, we obtain density, an intensive property. An **intensive property** is *independent* of the amount of matter observed. Thus, the density of pure water at 25 °C has a unique value, whether the sample fills a small beaker (small mass/small volume) or a swimming pool (large mass/large volume). Intensive properties are especially useful in chemical studies because they can often be used to identify substances.

The SI base units of mass and volume are kilograms and cubic meters, respectively, but chemists generally express mass in grams and volume in cubic centimeters or milliliters. Thus, the most commonly encountered density unit is grams per cubic centimeter (g/cm^3) or the identical unit grams per milliliter (g/mL).

The mass of 1.000 L of water at 4 °C is 1.000 kg. The density of water at 4 °C is 1000 g/1000 mL, or 1.000 g/mL. At 20 °C, the density of water is 0.9982 g/mL. Density is a function of temperature because volume varies with temperature, whereas mass remains constant. One reason that climate change is a concern is because as the average temperature of seawater increases, the seawater will become less dense, its volume will increase, and sea level will rise—*even if no continental ice melts.*

Like temperature, the state of matter affects the density of a substance. In general, solids are denser than liquids and both are denser than gases, but there are notable overlaps in densities between solids and liquids. Following are the ranges of values generally observed for densities; this information should prove useful in solving problems.

- Solid densities: from about 0.2 g/cm^3 to 20 g/cm^3
- Liquid densities: from about 0.5 g/mL to 3–4 g/mL
- Gas densities: mostly in the range of a few grams per liter

KEEP IN MIND

that recognizing the *scale of things* is one important step in avoiding mistakes. If a solid density calculates out as 0.05 g/cm^3, or a gas density as 5.0 g/cm^3, review the work done up to that point!

In general, densities of liquids are known more precisely than those of solids (which may have imperfections in their microscopic structures). Also, densities of elements and compounds are known more precisely than densities of materials with variable compositions (such as wood or rubber).

There are several important consequences of the different densities of solids and liquids. A solid that is insoluble and floats on a liquid is *less* dense than the liquid, and it displaces a *mass* of liquid equal to its own mass. An insoluble solid that sinks to the bottom of a liquid is *more* dense than the liquid and displaces a *volume* of liquid equal to its own volume. Liquids that are immiscible in each other separate into distinct layers, with the most dense liquid at the bottom and the least dense liquid at the top.

1-4 CONCEPT ASSESSMENT

Approximately what fraction of its volume is submerged when a 1.00 kg block of wood ($d = 0.68\ g/cm^3$) floats on water?

Density in Conversion Pathways

KEEP IN MIND

that in a conversion pathway, all units must cancel except for the desired unit in the final result (see Appendix A-5). Also, note that the quantities given and sought are typically *extensive* properties and the conversion factor(s) are often *intensive* properties (here, density).

If we measure the mass of an object and its volume, simple division gives us its density. Conversely, if we know the density of an object, we can use density as a conversion factor to determine the object's mass or volume. For example, a cube of osmium 1.000 cm on edge weighs 22.59 g. The density of osmium (the densest of the elements) is 22.59 g/cm^3. What would be the mass of a cube of osmium that is 1.25 in. on edge (1 in. = 2.54 cm)? To solve this problem, we begin by relating the volume of a cube to its length, that is, $V = l^3$. Then we can map out the *conversion pathway*:

$$\text{in. osmium} \longrightarrow \text{cm osmium} \longrightarrow \text{cm}^3\ \text{osmium} \longrightarrow \text{g osmium}$$

(converts in. to cm) (converts cm to cm^3) (converts cm^3 to g osmium)

$$?\ \text{g osmium} = \left[1.25\ \cancel{\text{in.}} \times \frac{2.54\ \cancel{\text{cm}}}{1\ \cancel{\text{in.}}}\right]^3 \times \frac{22.59\ \text{g osmium}}{1\ \cancel{\text{cm}^3}} = 723\ \text{g osmium}$$

At 25 °C the density of mercury, the only metal that is liquid at this temperature, is 13.5 g/mL. Suppose we want to know the volume, in mL, of 1.000 kg of mercury at 25 °C. We proceed by (1) identifying the known information: 1.000 kg of mercury and $d = 13.5$ g/mL (at 25 °C); (2) noting what we are trying to determine—a volume in milliliters (which we designate mL mercury); and (3) looking for the relevant conversion factors. Outlining the conversion pathway will help us find these conversion factors:

$$\text{kg mercury} \longrightarrow \text{g mercury} \longrightarrow \text{mL mercury}$$

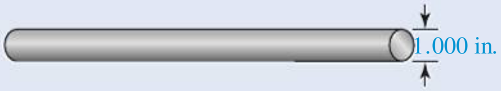
We need the factor 1000 g/kg to convert from kilograms to grams. Density provides the factor to convert from mass to volume. But in this instance, we need to use density in the *inverted* form. That is,

$$?\ \text{mL mercury} = 1.000\ \cancel{\text{kg}} \times \frac{1000\ \cancel{\text{g}}}{1\ \cancel{\text{kg}}} \times \frac{1\ \text{mL mercury}}{13.5\ \cancel{\text{g}}} = 74.1\ \text{mL mercury}$$

Examples 1-2 and 1-3 further illustrate that numerical calculations involving density are generally of two types: determining density from mass and volume measurements and using density as a conversion factor to relate mass and volume.

EXAMPLE 1-2 Relating Mass, Volume, and Density

The stainless steel in the solid cylindrical rod pictured below has a density of 7.75 g/cm^3. If we want a 1.00 kg mass of this rod, how long a section must we cut off? Refer to the inside back cover for the formula to calculate the volume of a cylinder.



Analyze

We are given the density, d, and the desired mass, m. Because $d = m/V$, we can solve for V and then use the formula for the volume of a cylinder, $V = \pi r^2 h$, to calculate h, the length of rod we seek. Two different mass units (g and kg) and two different length units (centimeters and inches) appear in the information given in this problem, so we anticipate having to make at least two unit conversions. To avoid errors, we include units in all steps.

Solve

Solve equation (1.2) for V. The reciprocal of density, $1/d$, is a conversion factor for converting from mass to volume.

$$V = \frac{m}{d} = m \times \frac{1}{d}$$

Calculate the volume of the rod that will have a mass of 1.00 kg. A conversion from kg to g is required in this step.

$$V = 1.00\ \text{kg} \times \frac{1000\ \text{g}}{1\ \text{kg}} \times \frac{1\ \text{cm}^3}{7.75\ \text{g}} = 129\ \text{cm}^3$$

Solve $V = \pi r^2 h$ for h and then calculate h. We must be certain to use the radius of the rod (one-half the diameter) and to express the radius in centimeters.

$$h = \frac{V}{\pi r^2} = \frac{129\ \text{cm}^3}{3.1416 \times (0.500\ \text{in.} \times 2.54\ \text{cm}/1\ \text{in.})^2} = 25.5\ \text{cm}$$

Assess

One way to check whether our answer is correct is to work the problem in reverse. For example, we calculate $d = 1.00 \times 10^3\ \text{g}/[3.1416 \times (1.27\ \text{cm})^2 \times 25.5\ \text{cm}] = 7.74\ \text{g}/\text{cm}^3$, which is very close to the given density. We are confident that our answer, $h = 25.5$ cm, is correct.

PRACTICE EXAMPLE A: To determine the density of trichloroethylene, a liquid used to degrease electronic components, a flask is first weighed empty (108.6 g). It is then filled with 125 mL of the trichloroethylene to give a total mass of 291.4 g. What is the density of trichloroethylene in grams per milliliter?

PRACTICE EXAMPLE B: Suppose that instead of using the cylindrical rod of Example 1-2 to prepare a 1.000 kg mass we were to use a solid spherical ball of copper ($d = 8.96\ \text{g/cm}^3$). What must be the radius of this ball?

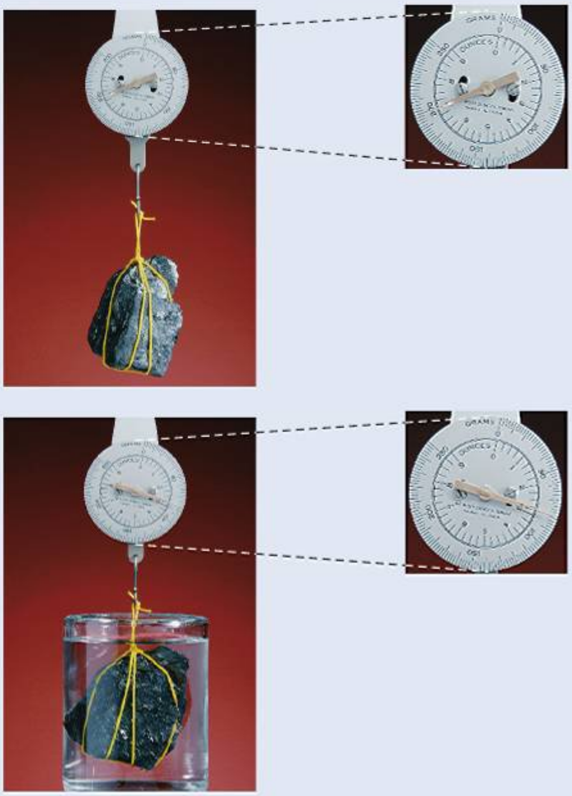
EXAMPLE 1-3 Determining the Density of an Irregularly Shaped Solid

A chunk of coal is weighed twice while suspended from a spring scale (see Figure 1-10). When the coal is suspended in air, the scale registers 156 g; when the coal is suspended underwater at 20 °C, the scale registers 59 g. What is the density of the coal? The density of water at 20 °C is 0.9982 $g\ cm^{-3}$.

Analyze

We need the ratio of mass to volume of the chunk of coal. The mass of the coal is easily obtained; it is what registers on the scale when the coal is suspended in air: 156 g. But what is the volume of this chunk of coal? The key to this calculation is the weight measurement under water. The coal weighs less than 156 g when submerged in water because the water exerts a buoyant force on the coal. The buoyant force is the difference

(continued)



▶ FIGURE 1-10
Measuring the volume of an irregularly shaped solid
When submerged in a liquid, an irregularly shaped solid displaces a volume of liquid equal to its own. The necessary data can be obtained by two mass measurements of the type illustrated here; the required calculations are like those in Example 1-3.

between the two weight measurements: 156 g − 59 g = 97 g. Recall the statement on page 14 that a submerged solid displaces a volume of water equal to its own volume. We don't know this volume of water directly, but we can use the mass of displaced water, 97 g, and its density, 0.9982 g/cm^3, to calculate the volume of displaced water. The volume of the coal is equal to the volume of displaced water.

Solve

The mass of the chunk of coal is 156 g. If we use m_{water} to denote the mass of displaced water, then the volume of the displaced water is calculated as follows:

$$V = \frac{m_{\text{water}}}{d} = \frac{156\text{ g} - 59\text{ g}}{0.9982\text{ g/cm}^3} = 97\text{ cm}^3$$

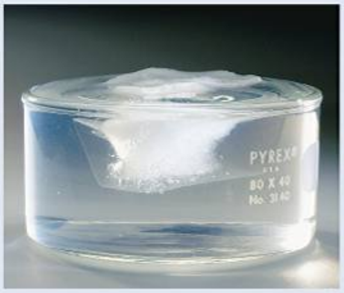
The volume of the chunk of coal is the same as the volume of displaced water. Therefore, the density of the coal is

$$d = \frac{156\text{ g}}{97\text{ cm}^3} = 1.6\text{ g/cm}^3$$

Assess

To determine the density of an object, we might think it is necessary to make measurements of both the mass and volume of the object. Example 1-3 shows that a volume measurement is not necessary. The steps in our calculation can be combined to give the following expression:

$$(\text{density of object})/(\text{density of water}) = (\text{weight in water})/(\text{weight in air} - \text{weight in water}).$$



The expression above clearly shows that the density of an object can be determined by making two weight measurements: one in air, and the other in a fluid (such as water) of known density.

PRACTICE EXAMPLE A: A graduated cylinder contains 33.8 mL of water. A stone with a mass of 28.4 g is placed in the cylinder and the water level rises to 44.1 mL. What is the density of the stone?

PRACTICE EXAMPLE B: In the situation shown in the photograph, when the ice cube melts completely, will the water overflow the container, will the water level in the container drop, or will the water level remain unchanged? Explain.

Percent Composition as a Conversion Factor

In Section 1-2, we described composition as an identifying characteristic of a sample of matter. A common way of referring to composition is through percentages. Percent (*per centum*) is the Latin for *per* (meaning "for each") and *centum* (meaning "100"). Thus, percent is the number of parts of a constituent in 100 parts of the whole. To say that a seawater sample contains 3.5% sodium chloride by mass means that there are 3.5 g of sodium chloride in every 100 g of the seawater. We make the statement in terms of grams because we are talking about percent *by mass*. We can express this percent by writing the following ratios:

$$\frac{3.5\text{ g sodium chloride}}{100\text{ g seawater}} \quad\text{and}\quad \frac{100\text{ g seawater}}{3.5\text{ g sodium chloride}} \qquad \textbf{(1.3)}$$

In Example 1-4, we will use one of these ratios as a conversion factor.

EXAMPLE 1-4 Using Percent Composition as a Conversion Factor

A 75 g sample of sodium chloride (table salt) is to be produced by evaporating to dryness a quantity of seawater containing 3.5% sodium chloride by mass. What volume of seawater, in liters, must be taken for this purpose? Assume a density of 1.03 g/mL for seawater.

Analyze

The conversion pathway is g sodium chloride → g seawater → mL seawater → L seawater. To convert from g sodium chloride to g seawater, we need the conversion factor in expression (1.3), with g seawater in the numerator and g sodium chloride in the denominator. To convert from g seawater to mL of seawater, we use the reciprocal of the density of seawater as the conversion factor. To make the final conversion, from mL seawater to L of seawater, we use the fact that 1 L = 1000 mL.

Solve

Following the conversion pathway described above, we obtain

$$\begin{aligned} ?\text{ L seawater} &= 75\ \cancel{\text{g sodium chloride}} \times \frac{100\ \cancel{\text{g seawater}}}{3.5\ \cancel{\text{g sodium chloride}}} \\ &\quad \times \frac{1\ \cancel{\text{mL seawater}}}{1.03\ \cancel{\text{g seawater}}} \times \frac{1\text{ L seawater}}{1000\ \cancel{\text{mL seawater}}} \\ &= 2.1\text{ L seawater} \end{aligned}$$

Assess

In solving this problem, we set up a conversion pathway, and then we thought about the conversion factors that were required. We will make use of this approach throughout the text.

PRACTICE EXAMPLE A: How many kilograms of ethanol are present in 25 L of a gasohol solution that is 90% gasoline to 10% ethanol by mass? The density of gasohol is 0.71 g/mL.

PRACTICE EXAMPLE B: Common rubbing alcohol is a solution of 70.0% isopropyl alcohol by mass in water. If a 25.0 mL sample of rubbing alcohol contains 15.0 g of isopropyl alcohol, what is the density of the rubbing alcohol?

1-2 ARE YOU WONDERING...

When to multiply and when to divide in doing problems with percentages?

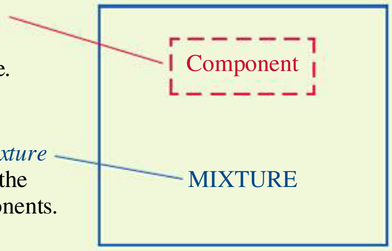
A common way of dealing with a percentage is to convert it to decimal form (3.5% becomes 0.035) and then to multiply or divide by this decimal, but students sometimes can't decide which to do. Expressing percentage as a conversion factor and

(continued)

using it to produce a necessary cancellation of units gets around this difficulty. Also, remember that

The quantity of a *component* must always be less than the quantity of the entire mixture. (*Multiply* by percentage.)

The quantity of the entire *mixture* must always be greater than the quantity of any of the components. (*Divide* by percentage.)



If, in Example 1-4, we had not been careful about the cancellation of units and had multiplied by percentage (3.5/100) instead of dividing by it (100/3.5), we would have obtained the numerical answer 2.5×10^{-3}. This would be a 2.5 mL sample of seawater, weighing about 2.5 g. Clearly, a sample of seawater that *contains* 75 g of sodium chloride must have a mass *greater than* 75 g.

KEEP IN MIND

that a numerical answer that defies common sense is probably wrong.

1-6 Uncertainties in Scientific Measurements

All measurements are subject to error. To some extent, measuring instruments have built-in, or inherent, errors, called **systematic errors**. (For example, a kitchen scale might consistently yield results that are 25 g too high or a thermometer a reading that is 2°C too low.) Limitations in an experimenter's skill or ability to read a scientific instrument also lead to errors and give results that may be either too high or too low. Such errors are called **random errors**.

▶ *Random errors* are observed by scatter in the data and can be dealt with effectively by taking the average of many measurements. *Systematic errors*, conversely, are the bane of the experimental scientist. They are not readily apparent and must be avoided by carefully calibrating a method against a known sample or result. Systematic errors influence the *accuracy* of a measurement, whereas random errors are linked to the *precision* of measurements.

Precision refers to the degree of reproducibility of a measured quantity—that is, the closeness of agreement when the same quantity is measured several times. The precision of a series of measurements is *high* (or good) if each of a series of measurements deviates by only a small amount from the average. Conversely, if there is wide deviation among the measurements, the precision is *poor* (or low). **Accuracy** refers to how close a measured value is to the accepted, or actual, value. High-precision measurements are not always accurate—a large systematic error could be present. (A tight cluster of three darts near the edge of a dart board can be considered precise but not very accurate if the intention was to strike the center of the board.) Still, scientists generally strive for high precision in measurements.

To illustrate these ideas, consider measuring the mass of an object by using the two balances shown on page 19. One of the balances is a single-pan balance that gives the mass in grams with only one decimal place. The other balance is a sophisticated analytical balance that gives the mass in grams with four decimal places. The accompanying table gives results obtained when the object is weighed three times on each balance. For the single-pan balance, the average of the measurements is 10.5 g, with measurements ranging from 10.4 g to 10.6 g. For the analytical balance, the average of the measurements is 10.4978 g, with measurements ranging from 10.4977 g to 10.4979 g. The scatter in the data obtained with the single-pan balance (±0.1 g) is greater than that obtained with the analytical balance (±0.0001 g). Thus, the results obtained by using the single-pan balance have lower (or poorer) precision than those obtained by using the analytical balance.

1-5 CONCEPT ASSESSMENT

Can a set of measurements be precise without being accurate? Can the average of a set of measurements be accurate and the individual measurements be imprecise? Explain.

1-7 Significant Figures

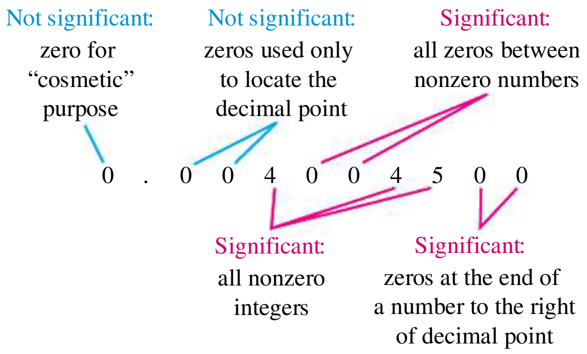
Consider these measurements made on a low-precision balance: 10.4, 10.2, and 10.3 g. The reported result is best expressed as their average, that is, 10.3 g.

A scientist would interpret these results to mean that the first two digits—10—are known with certainty and the last digit—3—is uncertain because it was estimated. That is, the mass is known only to the nearest 0.1 g, a fact that we could also express by writing 10.3 ± 0.1 g. To a scientist, the measurement 10.3 g is said to have *three* **significant figures**. If this mass is reported in kilograms rather than in grams, 10.3 g = 0.0103 kg, the measurement is still expressed to *three* significant figures even though more than three digits are shown. When measured on an analytical balance, the corresponding reported value might be 10.3107 g—a value with *six* significant figures. The number of significant figures in a measured quantity gives an indication of the capabilities of the measuring device and the precision of the measurements.

We will frequently need to determine the number of significant figures in a numerical quantity. The rules for doing this, outlined in Figure 1-11, are as follows:

- All nonzero digits are significant.
- Zeros are also significant, but with two important *exceptions* for quantities less than one. Any zeros (1) preceding the decimal point, or (2) following the decimal point and preceding the first nonzero digit, are *not* significant.
- The case of terminal zeros that precede the decimal point in quantities greater than one is *ambiguous*.

The quantity 7500 m is an example of an ambiguous case.



Not significant: zero for "cosmetic" purpose
Not significant: zeros used only to locate the decimal point
Significant: all zeros between nonzero numbers
0 . 0 0 4 0 0 4 5 0 0
Significant: all nonzero integers
Significant: zeros at the end of a number to the right of decimal point

▶ FIGURE 1-11
Determining the number of significant figures in a quantity
The quantity shown here, 0.004004500, has *seven* significant figures. All nonzero digits are significant, as are the indicated zeros.

Do we mean 7500 m, measured to the nearest meter? Nearest 10 meters? If all the zeros are significant—if the value has *four* significant figures—we can write 7500. m. That is, by writing a decimal point that is not otherwise needed, we show that all zeros preceding the decimal point are significant. This technique does not help if only one of the zeros, or if neither zero, is significant. The best approach here is to use exponential notation. (Review Appendix A if necessary.) The coefficient establishes the number of significant figures, and the power of ten locates the decimal point.

2 significant figures	*3 significant figures*	*4 significant figures*
7.5×10^3 m	7.50×10^3 m	7.500×10^3 m

Significant Figures in Numerical Calculations

Precision must neither be gained nor be lost in calculations involving measured quantities. There are several methods for determining how precisely to express the result of a calculation, but it is usually sufficient just to observe some simple rules involving significant figures.

▶ A more exact rule on multiplication/division is that the result should have about the same relative error—for example, expressed as parts per hundred (percent) or parts per thousand—as the least precisely known quantity. Usually the significant figure rule conforms to this requirement; occasionally, it does not (see Exercise 67).

The result of multiplication or division may contain only as many significant figures as the *least* precisely known quantity in the calculation.

In the following chain multiplication to determine the volume of a rectangular block of wood, we should round off the result to *three* significant figures. Figure 1-12 may help you to understand this.

$$\underset{(4\ \text{sig. fig.})}{14.79\ \text{cm}} \times \underset{(4\ \text{sig. fig.})}{12.11\ \text{cm}} \times \underset{(3\ \text{sig. fig.})}{5.05\ \text{cm}} = \underset{(3\ \text{sig. fig.})}{904\ \text{cm}^3}$$

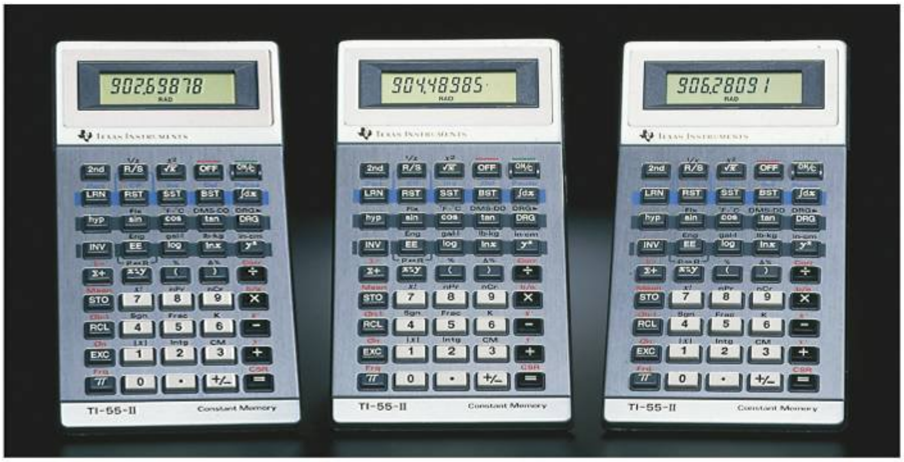
In adding and subtracting numbers, the applicable rule is as follows:

The result of addition or subtraction must be expressed with the same number of digits beyond the decimal point as the quantity carrying the *smallest* number of such digits.

▶ In addition and subtraction the *absolute* error in the result can be no less than the absolute error in the least precisely known quantity. In the summation at the right, the absolute error in one quantity is ±0.1 g; in another, ±0.01 g; and in the third, ±0.001 g. The sum *must* be expressed with an absolute error of ±0.1 g.

Consider the following sum of masses.

$$\begin{array}{r}
15.02\ \ \ \text{g} \\
9986.0\ \ \ \ \text{g} \\
3.518\ \text{g} \\
\hline
10{,}004.5\cancel{3}\cancel{8}\ \text{g}
\end{array}$$



▲ FIGURE 1-12
Significant-figure rule in multiplication
In forming the product 14.79 cm × 12.11 cm × 5.05 cm, the least precisely known quantity is 5.05 cm. Shown on the calculators are the products of 14.79 and 12.11 with 5.04, 5.05, and 5.06, respectively. In the three results, only the first two digits, 90 . . . , are identical; variations begin in the third digit. We are certainly not justified in carrying digits beyond the third. We express the volume as 904 cm^3. Usually, instead of a detailed analysis of the type done here, we can use a simpler idea: *The result of a multiplication may contain only as many significant figures as does the least precisely known quantity.*

The sum has the same uncertainty, ±0.1 g, as does the term with the *smallest* number of digits beyond the decimal point, 9986.0 g. Note that this calculation is *not* limited by significant figures. In fact, the sum has more significant figures (six) than do any of the terms in the addition.

◀ Later in the text, we will need to apply ideas about significant figures to logarithms. This concept is discussed in Appendix A.

There are two situations when a quantity appearing in a calculation may be *exact*, that is, not subject to errors in measurement. This may occur

- by definition (such as 1 min = 60 s, or 1 in. = 2.54 cm)
- as a result of counting (such as *six* faces on a cube, or *two* hydrogen atoms in a water molecule)

Exact numbers can be considered to have an unlimited number of significant figures.

1-6 CONCEPT ASSESSMENT

Which of the following is a more precise statement of the length 1 inch: 1 in. = 2.54 cm or 1 m = 39.37 in.? Explain.

◀ As added practice in working with significant figures, review the calculations in Section 1-6. You will note that they conform to the significant figure rules presented here.

Rounding Off Numerical Results

To three significant figures, we should express 15.453 as 15.5 and 14,775 as 1.48×10^4. If we need to drop just one digit, that is, to round off a number, the rule that we will follow is to increase the final digit by one unit if the digit dropped is 5, 6, 7, 8, or 9 and to leave the final digit unchanged if the digit dropped is 0, 1, 2, 3, or 4.* To three significant figures, 15.44 rounds off to 15.4, and 15.45 rounds off to 15.5.

◀ Some people prefer the "*round 5 to even*" rule. Thus 15.55 rounds to 15.6, and 17.65 rounds to 17.6. In banking and with large data sets, rounding needs to be unbiased. With a small number of data, this is less important.

---

*C. J. Guare, *J. Chem. Educ.*, **68**, 818 (1991).

EXAMPLE 1-5 Applying Significant Figure Rules: Multiplication/Division

Express the result of the following calculation with the correct number of significant figures.

$$\frac{0.225 \times 0.0035}{2.16 \times 10^{-2}} = ?$$

Analyze

By inspecting the three quantities, we see that the least precisely known quantity, 0.0035, has *two* significant figures. Our result must also contain only *two* significant figures.

Solve

When we carry out the calculation above by using an electronic calculator, the result is displayed as 0.0364583. In our analysis of this problem, we determined that the result must be rounded off to two significant figures, and so the result is properly expressed as 0.036 or as 3.6×10^{-2}.

Assess

To check for any possible calculation error, we can estimate the correct answer through a quick mental calculation by using exponential numbers. The answer should be $(2 \times 10^{-1})(4 \times 10^{-3})/(2 \times 10^{-2}) \approx 4 \times 10^{-2}$, and it is. Expressing numbers in exponential notation can often help us quickly estimate what the result of a calculation should be.

PRACTICE EXAMPLE A: Perform the following calculation, and express the result with the appropriate number of significant figures.

$$\frac{62.356}{0.000456 \times 6.422 \times 10^{3}} = ?$$

PRACTICE EXAMPLE B: Perform the following calculation, and express the result with the appropriate number of significant figures.

$$\frac{8.21 \times 10^{4} \times 1.3 \times 10^{-3}}{0.00236 \times 4.071 \times 10^{-2}} = ?$$

EXAMPLE 1-6 Applying Significant Figure Rules: Addition/Subtraction

Express the result of the following calculation with the correct number of significant figures.

$$(2.06 \times 10^{2}) + (1.32 \times 10^{4}) - (1.26 \times 10^{3}) = ?$$

Analyze

If the calculation is performed with an electronic calculator, the quantities can be entered just as they are written, and the answer obtained can be adjusted to the correct number of significant figures. To determine the correct number of significant figures, identify the largest quantity, and then write the other quantities with the same power of ten as appears in the largest quantity. The answer can have no more digits beyond the decimal point than the quantity having the smallest number of such digits.

Solve

The largest quantity is 1.32×10^{4} and thus, we write the other two quantities as 0.0206×10^{4} and 0.126×10^{4}. The result of the required calculation must be rounded off to two decimal places.

$$\begin{aligned}
&(2.06 \times 10^{2}) + (1.32 \times 10^{4}) - (1.26 \times 10^{3}) \\
&= (0.0206 \times 10^{4}) + (1.32 \times 10^{4}) - (0.126 \times 10^{4}) \\
&= (0.0206 + 1.32 - 0.126) \times 10^{4} \\
&= 1.2146 \times 10^{4} \\
&= 1.21 \times 10^{4}
\end{aligned}$$

Assess

If you refer back to the margin note on page 20, you will see that there is another way to approach this problem. To determine the absolute error in the least precisely known quantity, we write the three quantities as $(2.06 \pm 0.01) \times 10^2$, $(1.32 \pm 0.01) \times 10^4$ and $(1.26 \pm 0.01) \times 10^3$. We conclude that 1.32×10^4 has the largest absolute error ($\pm 0.01 \times 10^4$) and so, the absolute error in the result of the calculation above is also $\pm 0.01 \times 10^4$. Thus, 1.2146×10^4 is rounded to 1.21×10^4.

PRACTICE EXAMPLE A: Express the result of the following calculation with the appropriate number of significant figures.

$$0.236 + 128.55 - 102.1 = ?$$

PRACTICE EXAMPLE B: Perform the following calculation, and express the result with the appropriate number of significant figures.

$$\frac{(1.302 \times 10^3) + 952.7}{(1.57 \times 10^2) - 12.22} = ?$$

In working through the preceding examples, you likely used an electronic calculator. What's nice about using electronic calculators is that we don't have to write down intermediate results. In general, disregard occasional situations where intermediate rounding may be justified and store all intermediate results in your electronic calculator without regard to significant figures. Then, round off to the correct number of significant figures only in the final answer.

KEEP IN MIND

that addition and subtraction are governed by one significant-figure rule, and multiplication and division are governed by a different rule.

MasteringCHEMISTRY www.masteringchemistry.com

In the late 1960s, scientists heatedly debated the reported discovery of a new form of water called polywater. For a discussion of the polywater debate and the importance of the scientific method in helping the scientific community reach a consensus, go to the Focus On feature for Chapter 1 (The Scientific Method at Work: Polywater) on the MasteringChemistry site.

Summary

1-1 The Scientific Method—The **scientific method** is a set of procedures used to develop explanations of natural phenomena and possibly to predict additional phenomena. The four basic stages of the scientific method are (1) gathering data through observations and experiments; (2) reducing the data to simple verbal or mathematical expressions known as **natural laws**; (3) offering a plausible explanation of the data through a **hypothesis**; (4) testing the hypothesis through predictions and further experimentation, leading ultimately to a conceptual model called a **theory** that explains the hypothesis, often together with other related hypotheses.

1-2 Properties of Matter—**Matter** is defined as anything that occupies space, possesses mass, and displays inertia. **Composition** refers to the component parts of a sample of matter and their relative proportions. **Properties** are the qualities or attributes that distinguish one sample of matter from another. Properties of matter can be grouped into two broad categories: **physical** and **chemical**. Matter can undergo two types of changes: **chemical changes** or **reactions** are changes in composition; **physical changes** are changes in state or physical form and do not affect composition.

1-3 Classification of Matter—The basic building blocks of matter are called **atoms**. Matter that is composed of a collection of a single type of atom is known as an **element**. A sample of matter composed of two or more elements is known as a **compound**. A **molecule** is the smallest entity of a compound having the same proportions of the constituent atoms as does the compound as a whole. Collectively, elements and compounds compose the types of matter called **substances**. **Mixtures** of substances can be classified as **homogeneous** or **heterogeneous** (Fig. 1-4). The three states of matter are **solid**, **liquid**, and **gas**.

1-4 Measurement of Matter: SI (Metric) Units—Chemistry is a quantitative science, meaning that chemical measurements are usually expressed in terms of a number and an accompanying unit. The scientific system of measurement, called the *Système Internationale d'Unités* (abbreviated **SI**), involves seven base quantities (Table 1.1). **Mass** describes a quantity of matter. Weight measures the force of gravity on an object; weight is related to, but different from, mass. The temperature scales used by chemists are the **Celsius** and **Kelvin** scales. The **Fahrenheit** temperature scale, commonly used in daily life in the United States, is also used in some industrial settings. The three temperature scales can be related algebraically (Fig. 1-8).

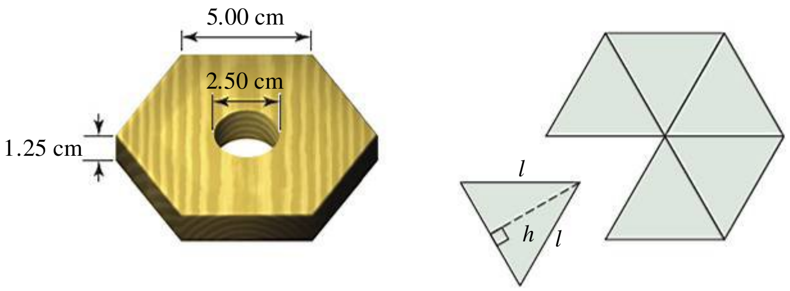
1-5 Density and Percent Composition: Their Use in Problem Solving—Mass and volume are **extensive properties**; they *depend* on the amount of matter in a sample. **Density**, the ratio of the mass of a sample to its volume, is an **intensive property**, a property *independent* of the amount of matter sampled. Density is used as a conversion factor in a variety of calculations.

1-6 Uncertainties in Scientific Measurements—Measurements are subject to **systematic** and **random errors**. In making a series of measurements, the degree to which the measurements agree with one another is known as the **precision** of the measurement, while the degree to which the measurement agrees with the actual value is referred to as the **accuracy** of the measurement.

1-7 Significant Figures—The proper use of **significant figures** is important in that it prevents the suggestion of a higher degree of precision in a calculated quantity than is warranted by the precision of the measured quantities used in the calculation. The precision of an answer cannot be greater than the precision of the numbers used in the calculation. In addition to reporting the correct number of significant figures in a calculated quantity, it is important to know the rules for rounding off numerical results.

Integrative Example

Consider a 58.35 g hexagonal block of wood that is 5.00 cm on edge and 1.25 cm thick, with a 2.50 cm diameter hole drilled through its center. Also given are the densities of the liquids hexane ($d = 0.667$ g/mL) and decane ($d = 0.845$ g/mL). Assume that the density of a mixture of the two liquids is a linear function of the volume percent composition of the solution. Determine the volume percent of hexane required in the solution so that the hexagonal block of wood will just barely float on the solution.



Analyze

The first task is to determine the density of the wood block, $d = m/V$. The mass is given, so the critical calculation is that of the volume. The key to the volume calculation is recognizing that the volume of the block is the *difference* between two volumes: The volume of the block if there were no hole *minus* the volume of the cylindrical hole. The second task is to write a simple equation relating density to the volume percent composition of the liquid solution, and then to solve that equation for the volume percent hexane that yields a solution density equal to the density calculated for the wood.

Solve

The solid hexagonal block can be divided into six smaller blocks, each an equilateral triangle of length, l, and height, h. The area of a triangle is given by the formula

$$A = \frac{1}{2}(\text{base} \times \text{height}) = \frac{1}{2} \times l \times h$$

Only the base, l, is given (5.00 cm). To express h in terms of l, we use the Pythagorean theorem for the right triangle pictured, that is, $a^2 + b^2 = c^2$, rearranged to the form $a^2 = c^2 - b^2$.

$$h^2 = l^2 - \left(\frac{l}{2}\right)^2 = l^2 - \frac{l^2}{4} = \frac{3l^2}{4} \text{ and}$$

$$h = \frac{\sqrt{3}}{2} \times l$$

Now, for the area of one of the six triangles we have

$$A = \frac{1}{2} \times l \times \frac{\sqrt{3}}{2} \times l = \frac{\sqrt{3}}{4} \times l^2$$

Substituting $l = 5.00$ cm and multiplying the cross-sectional area by the thickness, 1.25 cm, we obtain a volume of

$$V = \frac{\sqrt{3}}{4} \times (5.00\ \text{cm})^2 \times 1.25\ \text{cm} = 13.5\ \text{cm}^3$$

The volume of the hexagonal block of wood, without the cylindrical hole, is that of six triangular blocks.

$$V = 6 \times 13.5\ \text{cm}^3 = 81.0\ \text{cm}^3$$

The volume of the cylindrical hole with a radius of 1.25 cm (one-half the 2.50 cm diameter) and a height of 1.25 cm is

$$\begin{aligned} V &= \pi r^2 h = 3.1416 \times (1.25\ \text{cm})^2 \times 1.25\ \text{cm} \\ &= 6.14\ \text{cm}^3 \end{aligned}$$

The volume of the block of wood is the difference

$$V = 81.0\ \text{cm}^3 - 6.14\ \text{cm}^3 = 74.9\ \text{cm}^3$$

The density of the wood is

$$d = \frac{m}{V} = \frac{58.35\ \text{g}}{74.9\ \text{cm}^3} = 0.779\ \text{g/cm}^3 \text{ or } 0.779\ \text{g/mL}$$

The general formula for a linear (straight-line) relationship is

$$y = mx + b$$

In the present case, let y represent the density, d, of a solution (in g/mL) and x, the volume fraction of hexane (volume percent/100). By substituting the density of pure decane into the equation, we note that $x = 0$ and find that $b = 0.845$.

$$d = 0.845 = (m \times 0) + b$$

Now, using the density of pure hexane, $d = 0.667$, and the values $x = 1.00$ and $b = 0.845$, we obtain the value of m.

$$\begin{aligned} d &= 0.667 = (m \times 1.00) + 0.845 \\ m &= 0.667 - 0.845 = -0.178 \end{aligned}$$

Our final step is to find the value of x for a solution having the same density as the wood: 0.779 g/mL.

$$\begin{aligned} d &= 0.779 = -0.178x + 0.845 \\ x &= \frac{0.845 - 0.779}{0.178} = 0.37 \end{aligned}$$

The volume fraction of hexane is 0.37, and the volume percent composition of the solution is 37% hexane and 63% decane.

Assess

There is an early point in this calculation where we can check the correctness of our work. We have two expectations for the density of the block of wood: (1) it should be less than 1 g/cm^3 (practically all wood floats on water), and (2) it must fall between 0.667 g/cm^3 and 0.845 g/cm^3. If the calculated density of the wood were outside this range, the block of wood would either float on both liquids or sink in both of them, making the rest of the calculation impossible.

Another point to notice in this calculation is that we are justified in carrying three significant figures throughout the calculation up to the last step. There, because we must take the difference between two numbers of similar magnitudes, the number of significant figures drops from three to two.

PRACTICE EXAMPLE A: Magnalium is a solid mixture (an alloy) of aluminum metal and magnesium metal. An irregularly shaped chunk of a sample of magnalium is weighed twice, once in air and once in vegetable oil, by using a spring scale (see Figure 1-10). The weight in air is 211.5 g and the weight in oil is 135.3 g. If the densities of pure aluminum, pure magnesium, and vegetable oil are 2.70 g/cm^3, 1.74 g/cm^3, and 0.926 g/cm^3, respectively, then what is the mass percent of magnesium in this chunk of magnalium? Assume that the density of a mixture of the two metals is a linear function of the mass percent composition.

PRACTICE EXAMPLE B: A particular sample of seawater has a density of 1.027 g/cm^3 at 10 °C and is 2.67% sodium chloride by mass. Given that sodium chloride is 39.34% sodium by mass and that the mass of a single sodium atom is 3.817×10^{-26} kg, calculate the maximum mass of sodium and the maximum number of sodium atoms that can be extracted from a 1.5 L sample of this seawater.

MasteringCHEMISTRY

You'll find a link to additional self study questions in the study area on www.masteringchemistry.com

Exercises

(see also Appendices A-1 and A-5)

The Scientific Method

1. What are the principal reasons that one theory might be adopted over a conflicting one?

2. Can one predict how many experiments are required to verify a natural law? Explain.

3. A common belief among scientists is that there exists an underlying order to nature. Einstein described this belief in the words "God is subtle, but He is not malicious." What do you think Einstein meant by this remark?

4. Describe several ways in which a scientific law differs from a legislative law.

5. Describe the necessary characteristics of an experiment that is suitable to test a theory.

6. Describe the necessary characteristics of a scientific theory.

Properties and Classification of Matter

7. State whether the following properties of matter are physical or chemical.
(a) An iron nail is attracted to a magnet.
(b) A piece of paper spontaneously ignites when its temperature reaches 451 °F.
(c) A bronze statue develops a green coating (patina) over time.
(d) A block of wood floats on water.

8. State whether the following properties are physical or chemical.
(a) A piece of sliced apple turns brown.
(b) A slab of marble feels cool to the touch.
(c) A sapphire is blue.
(d) A clay pot fired in a kiln becomes hard and covered by a glaze.

9. Indicate whether each sample of matter listed is a substance or a mixture; if it is a mixture, indicate whether it is homogeneous or heterogeneous.
(a) clean fresh air
(b) a silver-plated spoon
(c) garlic salt
(d) ice

10. Indicate whether each sample of matter listed is a substance or a mixture; if it is a mixture, indicate whether it is homogeneous or heterogeneous.
(a) a wooden beam
(b) red ink
(c) distilled water
(d) freshly squeezed orange juice

11. Suggest physical changes by which the following mixtures can be separated.
(a) iron filings and wood chips
(b) ground glass and sucrose (cane sugar)
(c) water and olive oil
(d) gold flakes and water

12. What type of change—physical or chemical—is necessary to separate the following?
[*Hint:* Refer to a listing of the elements.]
(a) sugar from a sand/sugar mixture
(b) iron from iron oxide (rust)
(c) pure water from seawater
(d) water from a slurry of sand in water

Exponential Arithmetic

13. Express each number in exponential notation. **(a)** 8950.; **(b)** 10,700.; **(c)** 0.0240; **(d)** 0.0047; **(e)** 938.3; **(f)** 275,482.

14. Express each number in common decimal form. **(a)** 3.21×10^{-2}; **(b)** 5.08×10^{-4}; **(c)** 121.9×10^{-5}; **(d)** 16.2×10^{-2}.

15. Express each value in exponential form. Where appropriate, include units in your answer.
(a) speed of sound (sea level): 34,000 centimeters per second
(b) equatorial radius of Earth: 6378 kilometers
(c) the distance between the two hydrogen atoms in the hydrogen molecule: 74 trillionths of a meter
(d) $\dfrac{(2.2 \times 10^{3}) + (4.7 \times 10^{2})}{5.8 \times 10^{-3}} =$

16. Express each value in exponential form. Where appropriate, include units in your answer.
(a) solar radiation received by Earth: 173 thousand trillion watts
(b) average human cell diameter: 1 ten-millionth of a meter
(c) the distance between the centers of the atoms in silver metal: 142 trillionths of a meter
(d) $\dfrac{(5.07 \times 10^{4}) \times (1.8 \times 10^{-3})^{2}}{0.065 + (3.3 \times 10^{-2})} =$

Significant Figures

17. Indicate whether each of the following is an exact number or a measured quantity subject to uncertainty.
(a) the number of sheets of paper in a ream of paper
(b) the volume of milk in a liter bottle
(c) the distance between Earth and the sun
(d) the distance between the centers of the two oxygen atoms in the oxygen molecule

18. Indicate whether each of the following is an exact number or a measured quantity subject to uncertainty.
(a) the number of pages in this text
(b) the number of days in the month of January
(c) the area of a city lot
(d) the distance between the centers of the atoms in a gold medal

19. Express each of the following to *four* significant figures. **(a)** 3984.6; **(b)** 422.04; **(c)** 186,000; **(d)** 33,900; **(e)** 6.321×10^4; **(f)** 5.0472×10^{-4}.

20. How many significant figures are shown in each of the following? If this is indeterminate, explain why. **(a)** 450; **(b)** 98.6; **(c)** 0.0033; **(d)** 902.10; **(e)** 0.02173; **(f)** 7000; **(g)** 7.02; **(h)** 67,000,000

21. Perform the following calculations; express each answer in exponential form and with the appropriate number of significant figures.
(a) $0.406 \times 0.0023 =$
(b) $0.1357 \times 16.80 \times 0.096 =$
(c) $0.458 + 0.12 - 0.037 =$
(d) $32.18 + 0.055 - 1.652 =$

22. Perform the following calculations; express each number and the answer in exponential form and with the appropriate number of significant figures.
(a) $\dfrac{320 \times 24.9}{0.080} =$
(b) $\dfrac{432.7 \times 6.5 \times 0.002300}{62 \times 0.103} =$
(c) $\dfrac{32.44 + 4.9 - 0.304}{82.94} =$
(d) $\dfrac{8.002 + 0.3040}{13.4 - 0.066 + 1.02} =$

23. Perform the following calculations and retain the appropriate number of significant figures in each result.
(a) $(38.4 \times 10^{-3}) \times (6.36 \times 10^5) =$
(b) $\dfrac{(1.45 \times 10^2) \times (8.76 \times 10^{-4})}{(9.2 \times 10^{-3})^2} =$
(c) $24.6 + 18.35 - 2.98 =$
(d) $(1.646 \times 10^3) - (2.18 \times 10^2) + [(1.36 \times 10^4) \times (5.17 \times 10^{-2})] =$
(e)

$$\frac{-7.29 \times 10^{-4} + \sqrt{(7.29 \times 10^{-4})^2 + 4(1.00)(2.7 \times 10^{-5})}}{2 \times (1.00)}$$

[*Hint:* The significant figure rule for the extraction of a root is the same as for multiplication.]

24. Express the result of each of the following calculations in exponential form and with the appropriate number of significant figures.
(a)
$(4.65 \times 10^4) \times (2.95 \times 10^{-2}) \times (6.663 \times 10^{-3}) \times 8.2 =$
(b) $\dfrac{1912 \times (0.0077 \times 10^4) \times (3.12 \times 10^{-3})}{(4.18 \times 10^{-4})^3} =$
(c) $(3.46 \times 10^3) \times 0.087 \times 15.26 \times 1.0023 =$
(d) $\dfrac{(4.505 \times 10^{-2})^2 \times 1.080 \times 1545.9}{0.03203 \times 10^3} =$
(e)

$$\frac{(-3.61 \times 10^{-4}) + \sqrt{(3.61 \times 10^{-4})^2 + 4(1.00)(1.9 \times 10^{-5})}}{2 \times (1.00)}$$

[*Hint:* The significant figure rule for the extraction of a root is the same as for multiplication.]

25. An American press release describing the 1986 nonstop, round-the-world trip by the ultra-lightweight aircraft *Voyager* included the following data:

flight distance: 25,012 mi
flight time: 9 days, 3 minutes, 44 seconds
fuel capacity: nearly 9000 lb
fuel remaining at end of flight: 14 gal

To the maximum number of significant figures permitted, calculate
(a) the average speed of the aircraft in kilometers per hour
(b) the fuel consumption in kilometers per kilogram of fuel (assume a density of 0.70 g/mL for the fuel)

26. Use the concept of significant figures to criticize the way in which the following information was presented. "The estimated proved reserve of natural gas as of January 1, 1982, was 2,911,346 trillion cubic feet."

Units of Measurement

27. Perform the following conversions.
(a) 0.127 L = ____ mL
(b) 15.8 mL = ____ L
(c) 981 cm^3 = ____ L
(d) 2.65 m^3 = ____ cm^3

28. Perform the following conversions.
(a) 1.55 kg = ____ g
(b) 642 g = ____ kg
(c) 2896 mm = ____ cm
(d) 0.086 cm = ____ mm

29. Perform the following conversions from non-SI to SI units. (Use information from the inside back cover, as needed.)
(a) 68.4 in. = ____ cm
(b) 94 ft = ____ m
(c) 1.42 lb = ____ g
(d) 248 lb = ____ kg
(e) 1.85 gal = ____ dm^3
(f) 3.72 qt = ____ mL

30. Determine the number of the following:
(a) square meters (m^2) in 1 square kilometer (km^2)
(b) cubic centimeters (cm^3) in 1 cubic meter (m^3)
(c) square meters (m^2) in 1 square mile (mi^2) (1 mi = 5280 ft)

31. Which is the greater mass, 3245 μg or 0.00515 mg? Explain.

32. Which is the greater mass, 3257 mg or 0.000475 kg? Explain.

33. The non-SI unit, the hand (used by equestrians), is 4 inches. What is the height, in meters, of a horse that stands 15 hands high?

34. The unit *furlong* is used in horse racing. The units *chain* and *link* are used in surveying. There are exactly 8 furlongs in 1 mi, 10 chains in 1 furlong, and 100 links in 1 chain. To three significant figures, what is the length of 1 link in centimeters?

35. A sprinter runs the 100 yd dash in 9.3 s. At this same rate,
(a) how long would it take the sprinter to run 100.0 m?
(b) what is the sprinter's speed in meters per second?
(c) how long would it take the sprinter to run a distance of 1.45 km?

36. A non-SI unit of mass used in pharmaceutical work is the grain (gr) (15 gr = 1.0 g). An aspirin tablet contains 5.0 gr of aspirin. A 155 lb arthritic individual takes two aspirin tablets per day.
(a) What is the quantity of aspirin in two tablets, expressed in milligrams?
(b) What is the dosage rate of aspirin, expressed in milligrams of aspirin per kilogram of body mass?
(c) At the given rate of consumption of aspirin tablets, how many days would it take to consume 1.0 kg of aspirin?

37. In SI units, land area is measured in *hectares* (1 hectare = 1 hm^2). The commonly used unit for land area in the United States is the *acre*. How many acres correspond to 1 hectare? (1 mi^2 = 640 acres, 1 mi = 5280 ft, 1 ft = 12 in.).

38. In an engineering reference book, you find that the density of iron is 0.284 lb/in.^3. What is the density in g/cm^3?

39. In a user's manual accompanying an American-made automobile, a typical gauge pressure for optimal performance of automobile tires is 32 lb/in.^2. What is this pressure in grams per square centimeter and kilograms per square meter?

40. The volume of a red blood cell is about $90.0 \times 10^{-12}\ \text{cm}^3$. Assuming that red blood cells are spherical, what is the diameter of a red blood cell in millimeters?

Temperature Scales

41. We want to mark off a thermometer in both Celsius and Fahrenheit temperatures. On the Celsius scale, the lowest temperature mark is at −10 °C, and the highest temperature mark is at 50 °C. What are the equivalent Fahrenheit temperatures?

42. The highest and lowest temperatures on record for San Bernardino, California, are 118 °F and 17 °F, respectively. What are these temperatures on the Celsius scale?

43. The absolute zero of temperature is −273.15 °C. Should it be possible to achieve a temperature of −465 °F? Explain.

44. A family/consumer science class is given an assignment in candy-making that requires a sugar mixture to be brought to a "soft-ball" stage (234–240 °F). A student borrows a thermometer having a range from −10 °C to 110 °C from the chemistry laboratory to do this assignment. Will this thermometer serve the purpose? Explain.

45. You decide to establish a new temperature scale on which the melting point of mercury (−38.9 °C) is 0 °M, and the boiling point of mercury (356.9 °C) is 100 °M. What would be **(a)** the boiling point of water in °M; and **(b)** the temperature of absolute zero in °M?

46. You decide to establish a new temperature scale on which the melting point of ammonia (−77.75 °C) is 0 °A and the boiling point of ammonia (−33.35 °C) is 100 °A. What would be **(a)** the boiling point of water in °A; and **(b)** the temperature of absolute zero in °A?

Density

47. A 2.18 L sample of butyric acid, a substance present in rancid butter, has a mass of 2088 g. What is the density of butyric acid in grams per milliliter?

48. A 15.2 L sample of chloroform at 20 °C has a mass of 22.54 kg. What is the density of chloroform at 20 °C, in grams per milliliter?

49. To determine the density of acetone, a 55.0 gal drum is weighed twice. The drum weighs 75.0 lb when empty and 437.5 lb when filled with acetone. What is the density of acetone expressed in grams per milliliter?

50. To determine the volume of an irregularly shaped glass vessel, the vessel is weighed empty (121.3 g) and when filled with carbon tetrachloride (283.2 g). What is the volume capacity of the vessel, in milliliters, given that the density of carbon tetrachloride is 1.59 g/mL?

51. A solution consisting of 8.50% acetone and 91.5% water by mass has a density of 0.9867 g/mL. What mass of acetone, in kilograms, is present in 7.50 L of the solution?

52. A solution contains 10.05% sucrose (cane sugar) by mass. What mass of the solution, in grams, is needed for an application that requires 1.00 kg sucrose?

53. A fertilizer contains 21% nitrogen by mass. What mass of this fertilizer, in kilograms, is required for an application requiring 225 g of nitrogen?

54. A vinegar sample is found to have a density of 1.006 g/mL and to contain 5.4% acetic acid by mass. How many grams of acetic acid are present in 1.00 L of this vinegar?

55. Calculate the mass of a block of iron ($d = 7.86\ \text{g/cm}^3$) with dimensions of 52.8 cm × 6.74 cm × 3.73 cm.

56. Calculate the mass of a cylinder of stainless steel ($d = 7.75\ \text{g/cm}^3$) with a height of 18.35 cm and a radius of 1.88 cm.

57. The following densities are given at 20 °C: water, 0.998 g/cm^3; iron, 7.86 g/cm^3; aluminum, 2.70 g/cm^3. Arrange the following items in terms of *increasing* mass.

(a) a rectangular bar of iron,
81.5 cm × 2.1 cm × 1.6 cm

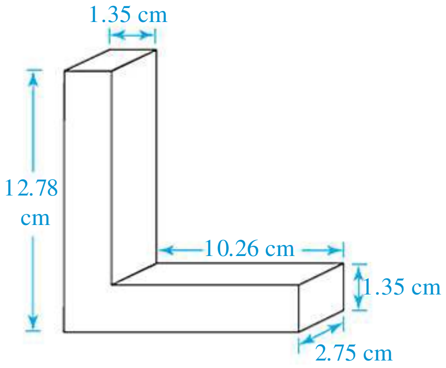
(b) a sheet of aluminum foil,
12.12 m × 3.62 m × 0.003 cm

(c) 4.051 L of water

58. To determine the approximate mass of a small spherical shot of copper, the following experiment is performed. When 125 pieces of the shot are counted out and added to 8.4 mL of water in a graduated cylinder, the total volume becomes 8.9 mL. The density of copper is 8.92 g/cm^3. Determine the approximate mass of a single piece of shot, assuming that all of the pieces are of the same dimensions.

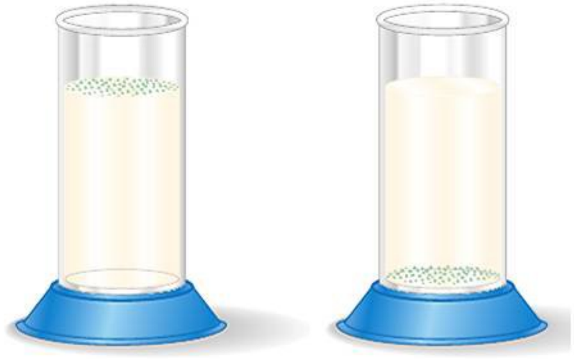
59. The density of aluminum is 2.70 g/cm^3. A square piece of aluminum foil, 22.86 cm on a side is found to weigh 2.568 g. What is the thickness of the foil, in millimeters?

60. The angle iron pictured here is made of steel with a density of 7.78 g/cm^3. What is the mass, in grams, of this object?



61. In normal blood, there are about 5.4×10^9 red blood cells per milliliter. The volume of a red blood cell is about 90.0×10^{-12} cm^3, and its density is 1.096 g/mL. How many liters of whole blood would be needed to collect 0.5 kg of red blood cells?

62. A technique once used by geologists to measure the density of a mineral is to mix two dense liquids in such proportions that the mineral grains just float. When a sample of the mixture in which the mineral calcite just floats is put in a special density bottle, the weight is 15.4448 g. When empty, the bottle weighs 12.4631 g, and when filled with water, it weighs 13.5441 g. What is the density of the calcite sample? (All measurements were carried out at 25 °C, and the density of water at 25 °C is 0.9970 g/mL).



▲ At the left, grains of the mineral *calcite* float on the surface of the liquid bromoform (d = 2.890 g/mL). At the right, the grains sink to the bottom of liquid chloroform (d = 1.444 g/mL). By mixing bromoform and chloroform in just the proportions required so that the grains barely float, the density of the calcite can be determined (Exercise 62).

Percent Composition

63. In a class of 76 students, the results of a particular examination were 7 A's, 22 B's, 37 C's, 8 D's, 2 F's. What was the percent distribution of grades, that is, % A's, % B's, and so on?

64. A class of 84 students had a final grade distribution of 18% A's, 25% B's, 32% C's, 13% D's, 12% F's. How many students received each grade?

65. A solution of sucrose in water is 28.0% sucrose by mass and has a density of 1.118 g/mL. What mass of sucrose, in grams, is contained in 3.50 L of this solution?

66. A solution containing 12.0% sodium hydroxide by mass in water has a density of 1.131 g/mL. What volume of this solution, in liters, must be used in an application requiring 2.25 kg of sodium hydroxide?

Integrative and Advanced Exercises

67. According to the rules on significant figures, the product of the measured quantities 99.9 m and 1.008 m should be expressed to three significant figures—101 m^2. Yet, in this case, it would be more appropriate to express the result to *four* significant figures—100.7 m^2. Explain why.

68. For a solution containing 6.38% para-diclorobenzene by mass in benzene, the density of the solution as a function of temperature (t) in the temperature range 15 to 65 °C is given by the equation

$$d(g/mL) = 1.5794 - 1.836 \times 10^{-3}(t - 15)$$

At what temperature will the solution have a density of 1.543 g/mL?

69. A solution used to chlorinate a home swimming pool contains 7% chlorine by mass. An ideal chlorine level for the pool is one part per million (1 ppm). (Think of 1 ppm as being 1 g chlorine per million grams of water.) If you assume densities of 1.10 g/mL for the chlorine solution and 1.00 g/mL for the swimming pool water, what volume of the chlorine solution, in liters, is required to produce a chlorine level of 1 ppm in an 18,000-gallon swimming pool?

70. A standard 1.000 kg mass is to be cut from a bar of steel having an equilateral triangular cross section with sides equal to 2.50 in. The density of the steel is 7.70 g/cm^3. How many inches long must the section of bar be?

71. The volume of seawater on Earth is about 330,000,000 mi^3. If seawater is 3.5% sodium chloride by mass and has a density of 1.03 g/mL, what is the approximate mass of sodium chloride, in tons, dissolved in the seawater on Earth (1 ton = 2000 lb)?

72. The diameter of metal wire is often referred to by its American wire-gauge number. A 16-gauge wire has a diameter of 0.05082 in. What length of wire, in meters, is found in a 1.00 lb spool of 16-gauge copper wire? The density of copper is 8.92 g/cm^3.

73. Magnesium occurs in seawater to the extent of 1.4 g magnesium per kilogram of seawater. What volume of seawater, in cubic meters, would have to be processed to produce 1.00×10^5 tons of magnesium (1 ton = 2000 lb)? Assume a density of 1.025 g/mL for seawater.

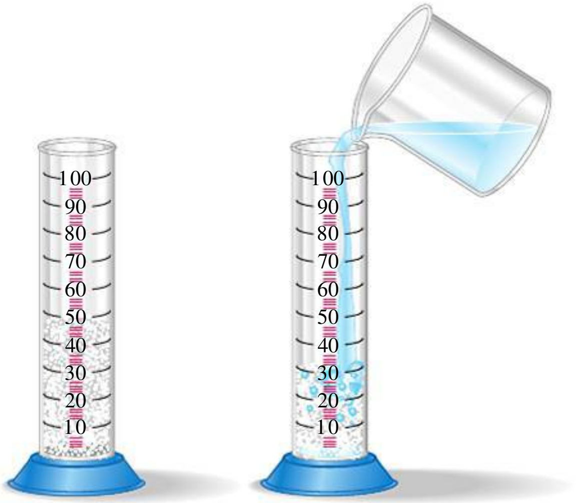
74. A typical rate of deposit of dust ("dustfall") from unpolluted air was reported as 10 tons per square mile per month. **(a)** Express this dustfall in milligrams per square meter per hour. **(b)** If the dust has an average density of 2 g/cm^3, how long would it take to accumulate a layer of dust 1 mm thick?

75. In the United States, volume of irrigation water is usually expressed in acre-feet. One acre-foot is a volume of water sufficient to cover 1 acre of land to a depth of 1 ft (640 acres = 1 mi^2; 1 mi = 5280 ft). The principal lake in the California Water Project is Lake Oroville, whose water storage capacity is listed as 3.54×10^6 acre-feet. Express the volume of Lake Oroville in **(a)** cubic feet; **(b)** cubic meters; **(c)** U.S. gallons.

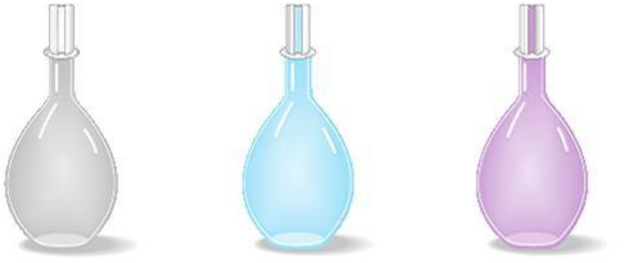
76. A Fahrenheit and a Celsius thermometer are immersed in the same medium. At what Celsius temperature will the numerical reading on the Fahrenheit thermometer be

- **(a)** 49° less than that on the Celsius thermometer;
- **(b)** twice that on the Celsius thermometer;
- **(c)** one-eighth that on the Celsius thermometer;
- **(d)** 300° more than that on the Celsius thermometer?

77. The accompanying illustration shows a 100.0 mL graduated cylinder half-filled with 8.0 g of diatomaceous earth, a material consisting mostly of silica and used as a filtering medium in swimming pools. How many milliliters of water are required to fill the cylinder to the 100.0 mL mark? The diatomaceous earth is insoluble in water and has a density of 2.2 g/cm^3.



78. The simple device pictured here, a pycnometer, is used for precise density determinations. From the data presented, together with the fact that the density of water at 20 °C is 0.99821 g/mL, determine the density of methanol, in grams per milliliter.



Empty
25.601 g

Filled with water
at 20 °C: 35.552 g

Filled with methanol
at 20 °C: 33.490 g

79. If the pycnometer of Exercise 78 is filled with ethanol at 20 °C instead of methanol, the observed mass is 33.470 g. What is the density of ethanol? How precisely could you determine the composition of an ethanol–methanol solution by measuring its density with a pycnometer? Assume that the density of the solution is a linear function of the volume percent composition.

80. A pycnometer (see Exercise 78) weighs 25.60 g empty and 35.55 g when filled with water at 20 °C. The density of water at 20 °C is 0.9982 g/mL. When 10.20 g lead is placed in the pycnometer and the pycnometer is again filled with water at 20 °C, the total mass is 44.83 g. What is the density of the lead in grams per cubic centimeter?

81. The Greater Vancouver Regional District (GVRD) chlorinates the water supply of the region at the rate of 1 ppm, that is, 1 kilogram of chlorine per million kilograms of water. The chlorine is introduced in the form of sodium hypochlorite, which is 47.62% chlorine. The population of the GVRD is 1.8 million persons. If each person uses 750 L of water per day, how many kilograms of sodium hypochlorite must be added to the water supply each week to produce the required chlorine level of 1 ppm?

82. A Boeing 767 due to fly from Montreal to Edmonton required refueling. Because the fuel gauge on the aircraft was not working, a mechanic used a dipstick to determine that 7682 L of fuel were left on the plane. The plane required 22,300 kg of fuel to make the trip. In order to determine the volume of fuel required, the pilot asked for the conversion factor needed to convert a volume of fuel to a mass of fuel. The mechanic gave the factor as 1.77. Assuming that this factor was in metric units (kg/L), the pilot calculated the volume to be added as 4916 L. This volume of fuel was added and the 767 subsequently ran out the fuel, but landed safely by gliding into Gimli Airport near Winnipeg. The error arose because the factor 1.77 was in units of pounds per liter. What volume of fuel should have been added?

83. The following equation can be used to relate the density of liquid water to Celsius temperature in the range from 0 °C to about 20 °C:

$$d(\mathrm{g/cm^3}) = \frac{0.99984 + (1.6945 \times 10^{-2}t) - (7.987 \times 10^{-6}t^2)}{1 + (1.6880 \times 10^{-2}t)}$$

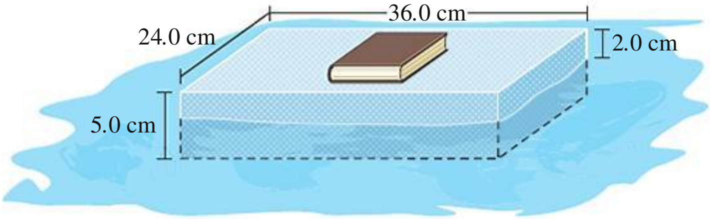
(a) To four significant figures, determine the density of water at 10 °C.

(b) At what temperature does water have a density of 0.99860 g/cm^3?

(c) In the following ways, show that the density passes through a maximum somewhere in the temperature range to which the equation applies.

- **(i)** by estimation
- **(ii)** by a graphical method
- **(iii)** by a method based on differential calculus

84. A piece of high-density Styrofoam measuring 24.0 cm by 36.0 cm by 5.0 cm floats when placed in a tub of water. When a 1.5 kg book is placed on top of the Styrofoam, the Styrofoam partially sinks, as illustrated in the diagram below. Assuming that the density of water is 1.00 g/mL, what is the density of Styrofoam?



85. A tabulation of data lists the following equation for calculating the densities (d) of solutions of naphthalene in benzene at 30 °C as a function of the mass percent of naphthalene.

$$d(\mathrm{g/cm^3}) = \frac{1}{1.153 - 1.82 \times 10^{-3}(\%N) + 1.08 \times 10^{-6}(\%N)^2}$$

Use the equation above to calculate **(a)** the density of pure benzene at 30 °C; **(b)** the density of pure naphthalene at 30 °C; **(c)** the density of solution at 30 °C that is 1.15% naphthalene; **(d)** the mass percent of naphthalene in a solution that has a density of 0.952 g/cm^3 at 30 °C. [*Hint*: For (d), you need to use the quadratic formula. See Section A-3 of Appendix A.]

86. The total volume of ice in the Antarctic is about 3.01×10^7 km^3. If all the ice in the Antarctic were to melt completely, estimate the rise, h, in sea level that would result from the additional liquid water entering the oceans. The densities of ice and fresh water are 0.92 g/cm^3 and 1.0 g/cm^3, respectively. Assume that the oceans of the world cover an area, A, of about 3.62×10^8 km^2 and that the increase in volume of the oceans can be calculated as $A \times h$.

87. An empty 3.00 L bottle weighs 1.70 kg. Filled with a certain wine, it weighs 4.72 kg. The wine contains 11.5% ethyl alcohol by mass. How many grams of ethyl alcohol are there in 250.0 mL of this wine?

88. The filament in an incandescent light bulb is made from tungsten metal ($d = 19.3$ g/cm^3) that has been drawn into a very thin wire. The diameter of the wire is difficult to measure directly, so it is sometimes estimated by measuring the mass of a fixed length of wire. If a 0.200 m length of tungsten wire weighs 42.9 mg, then what is the diameter of the wire? Express your answer in millimeters.

89. Blood alcohol content (BAC) is sometimes reported in weight-volume percent and, when it is, a BAC of 0.10% corresponds to 0.10 g ethyl alcohol per 100 mL of blood. In many jurisdictions, a person is considered legally intoxicated if his or her BAC is 0.10%. Suppose that a 68 kg person has a total blood volume of 5.4 L and breaks down ethyl alcohol at a rate of 10.0 grams per hour.* How many 145 mL glasses of wine, consumed over three hours, will produce a BAC of 0.10% in this 68 kg person? Assume the wine has a density of 1.01 g/mL and is 11.5% ethyl alcohol by mass. (*The rate at which ethyl alcohol is broken down varies dramatically from person to person. The value given here for the rate is a realistic, but not necessarily accurate, value.)

Feature Problems

90. In an attempt to determine any possible relationship between the year in which a U.S. penny was minted and its current mass (in grams), students weighed an assortment of pennies and obtained the following data.

1968	1973	1977	1980	1982	1983	1985
3.11	3.14	3.13	3.12	3.12	2.51	2.54
3.08	3.06	3.10	3.11	2.53	2.49	2.53
3.09	3.07	3.06	3.08	2.54	2.47	2.53

What valid conclusion(s) might they have drawn about the relationship between the masses of the pennies within a given year and from year to year?

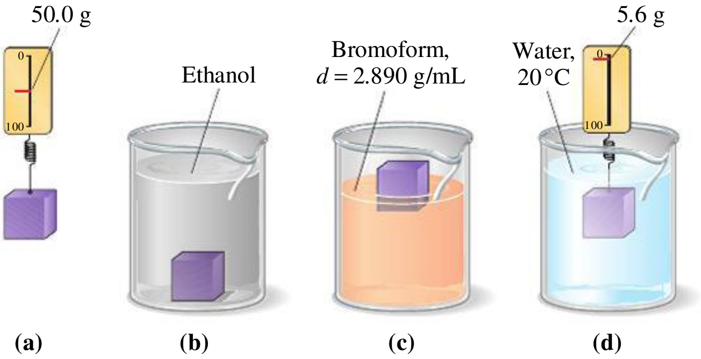
91. In the third century BC, the Greek mathematician Archimedes is said to have discovered an important principle that is useful in density determinations. The story told is that King Hiero of Syracuse (in Sicily) asked Archimedes to verify that an ornate crown made for him by a goldsmith consisted of pure gold and not a gold–silver alloy. Archimedes had to do this, of course, without damaging the crown in any way. Describe how Archimedes did this, or if you don't know the rest of the story, rediscover Archimedes's principle and explain how it can be used to settle the question.

92. The Galileo thermometer shown in the photograph is based on the dependence of density on temperature. The liquid in the outer cylinder and the liquid in the partially filled floating glass balls are the same except that a colored dye has been added to the liquid in the balls. Explain how the Galileo thermometer works.

93. The canoe gliding gracefully along the water in the photograph is made of concrete, which has a density of about 2.4 g/cm^3. Explain why the canoe does not sink.

UNIVERSITY OF KANSAS
THE ODYSSEY

94. The accompanying sketches suggest four observations made on a small block of plastic material. Tell what conclusions can be drawn from each sketch, and conclude by giving your best estimate of the density of the plastic.



95. As mentioned on page 13, the MCO was lost because of a mix-up in the units used to calculate the force needed to correct its trajectory. Ground-based computers generated the force correction file. On September 29, 1999, it was discovered that the forces reported by the ground-based computer for use in MCO navigation software were low by a factor of 4.45. The erroneous trajectory brought the MCO 56 km above the surface of Mars; the correct trajectory would have brought the MCO approximately 250 km above the surface. At 250 km, the MCO would have successfully entered the desired elliptic orbit. The data contained in the force correction file were delivered in lb-sec instead of the required SI units of newton-sec for the MCO navigation software. The newton is the SI unit of force and is described in Appendix B. The British Engineering (gravitational) system uses a pound (lb) as a unit of force and ft/s^2 as a unit of acceleration. In turn, the pound is defined as the pull of Earth on a unit of mass at a location where the acceleration due to gravity is 32.174 ft/s^2. The unit of mass in this case is the slug, which is 14.59 kg. Thus,

$$\text{BE unit of force} = 1 \text{ pound} = (\text{slug})(\text{ft/s}^2)$$

Use this information to confirm that

$$\begin{aligned}\text{BE unit of force} &= 4.45 \times \text{SI unit of force}\\ 1 \text{ pound} &= 4.45 \text{ newton}\end{aligned}$$

Self-Assessment Exercises

96. In your own words, define or explain the following terms or symbols: **(a)** mL; **(b)** % by mass; **(c)** °C; **(d)** density; **(e)** element.

97. Briefly describe each of the following ideas: **(a)** SI base units; **(b)** significant figures; **(c)** natural law; **(d)** exponential notation.

98. Explain the important distinctions between each pair of terms: **(a)** mass and weight; **(b)** intensive and extensive properties; **(c)** substance and mixture; **(d)** systematic and random errors; **(e)** hypothesis and theory.

99. The fact that the volume of a fixed amount of gas at a fixed temperature is inversely proportional to the gas pressure is an example of **(a)** a hypothesis; **(b)** a theory; **(c)** a paradigm; **(d)** the absolute truth; **(e)** a natural law.

100. A good example of a homogeneous mixture is
(a) a cola drink in a tightly capped bottle
(b) distilled water leaving a distillation apparatus
(c) oxygen gas in a cylinder used in welding
(d) the material produced in a kitchen blender

101. Compared with its mass on Earth, the mass of the same object on the moon should be **(a)** less; **(b)** more; **(c)** the same; **(d)** nearly the same, but somewhat less.

102. Of the following masses, two are expressed to the nearest milligram. The two are **(a)** 32.7 g; **(b)** 0.03271 kg; **(c)** 32.7068 g; **(d)** 32.707 g; **(e)** 30.7 mg; **(f)** 3×10^3 μg.

103. The highest temperature of the following group is **(a)** 217 K; **(b)** 273 K; **(c)** 217 °F; **(d)** 105 °C; **(e)** 373 K.

104. Which of the following quantities has the greatest mass?

(a) 752 mL of water at 20 °C
(b) 1.05 L of ethanol at 20 °C ($d = 0.789$ g/mL)
(c) 750 g of chloroform at 20 °C ($d = 1.483$ g/mL)
(d) a cube of balsa wood ($d = 0.11$ g/cm^3) that is 19.20 cm on edge

105. The density of water is 0.9982 g/cm^3 at 20 °C. Express the density of water at 20 °C in the following units: **(a)** g/L; **(b)** kg/m^3; **(c)** kg/km^3.

106. Two students each made four measurements of the mass of an object. Their results are shown in the table below.

	Student A	Student B
Four measurements:	51.6, 50.8, 52.2, 50.2 g	50.1, 49.6, 51.0, 49.4 g
Their average:	51.3 g	50.0 g

The exact mass of the object is 51.0 g. Whose results are more precise, Student A's or Student B's? Whose results are more accurate?

107. The reported value for the volume of a rectangular piece of cardboard with the dimensions 36 cm × 20.2 cm × 9 mm should be **(a)** 6.5×10^3 cm^3; **(b)** 7×10^2 cm^3; **(c)** 655 cm^3; **(d)** 6.5×10^2 cm^3.

108. List the following in the order of increasing precision, indicating any quantities about which the precision is uncertain: **(a)** 1400 km; **(b)** 1516 kg; **(c)** 0.00304 g; **(d)** 125.34 cm; **(e)** 2000 mg.

109. *Without doing detailed calculations*, explain which of the following objects contains the greatest mass of the element iron.

(a) A 1.00 kg pile of pure iron filings.

(b) A cube of wrought iron, 5.0 cm on edge. Wrought iron contains 98.5% iron by mass and has a density of 7.7 g/cm^3.

(c) A square sheet of stainless steel 0.30 m on edge and 1.0 mm thick. The stainless steel is an alloy (mixture) containing iron, together with 18% chromium, 8% nickel, and 0.18% carbon by mass. Its density is 7.7 g/cm^3.

(d) 10.0 L of a solution characterized as follows: $d = 1.295$ g/mL. This solution is 70.0% water and 30.0% of a compound of iron, by mass. The iron compound consists of 34.4% iron by mass.

110. A lump of pure copper weighs 25.305 g in air and 22.486 g when submerged in water ($d = 0.9982$ g/mL) at 20.0 °C. Suppose the copper is then rolled into a 248 cm^2 foil of uniform thickness. What will this thickness be, in millimeters?

111. Water, a compound, is a substance. Is there any circumstance under which a sample of pure water can exist as a heterogeneous mixture? Explain.

112. Appendix E describes a useful study aid known as concept mapping. Using the method presented in Appendix E, construct a concept map illustrating the different concepts presented in Sections 1-2, 1-3, and 1-4.

2-8 Using the Mole Concept in Calculations

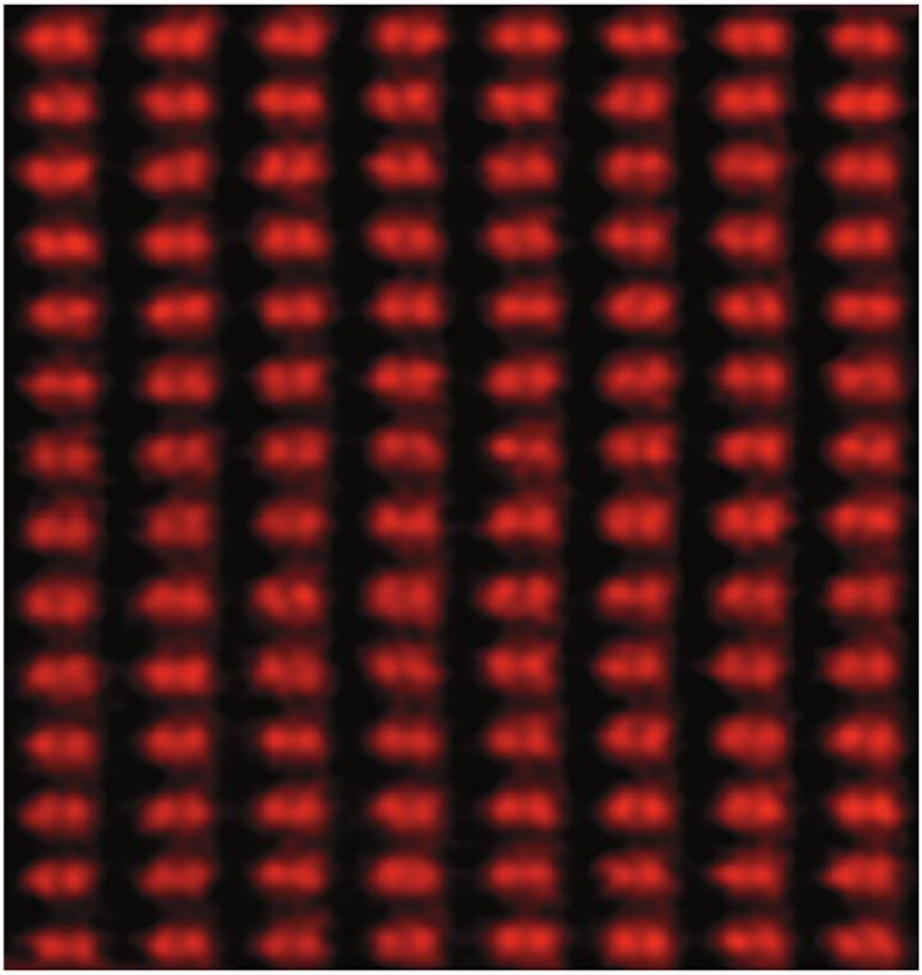

Image of silicon atoms that are only 78 pm apart; image produced by using a scanning transmission electron microscope (STEM). The hypothesis that all matter is made up of atoms has existed for more than 2000 years. It is only within the last few decades, however, that techniques have been developed that can render individual atoms visible.

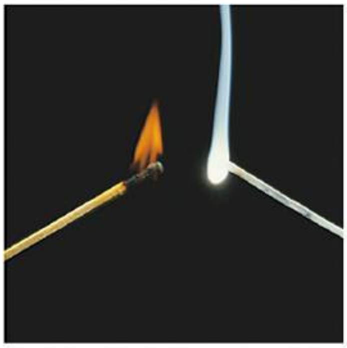
We begin this chapter with a brief survey of early chemical discoveries, culminating in Dalton's atomic theory. This is followed by a description of the physical evidence leading to the modern picture of the *nuclear atom*, in which protons and neutrons are combined into a nucleus with electrons in space surrounding the nucleus. We will also introduce the periodic table as the primary means of organizing elements into groups with similar properties. Finally, we will introduce the concept of the mole and the Avogadro constant, which are the principal tools for counting atoms and molecules and measuring amounts of substances. We will use these tools throughout the text.

2-1 Early Chemical Discoveries and the Atomic Theory

Chemistry has been practiced for a very long time, even if its practitioners were much more interested in its applications than in its underlying principles. The blast furnace for extracting iron from iron ore appeared as early as A.D. 1300, and such important chemicals as sulfuric acid (oil of vitriol), nitric acid (aqua fortis), and sodium sulfate (Glauber's salt) were all well known and used several hundred years ago. Before the end of the eighteenth century, the principal gases of the atmosphere—nitrogen and oxygen—had been isolated, and natural laws had been proposed describing the physical behavior of gases. Yet chemistry cannot be said to have entered the modern age until the process of combustion was explained. In this section, we explore the direct link between the explanation of combustion and Dalton's atomic theory.



▲ FIGURE 2-1
Two combustion reactions
The apparent product of the combustion of the match—the ash—weighs *less* than the match. The product of the combustion of the magnesium ribbon (the "smoke") weighs *more* than the ribbon. Actually, in each case, the total mass remains unchanged. To understand this, you have to know that oxygen gas enters into both combustions and that water and carbon dioxide are also products of the combustion of the match.

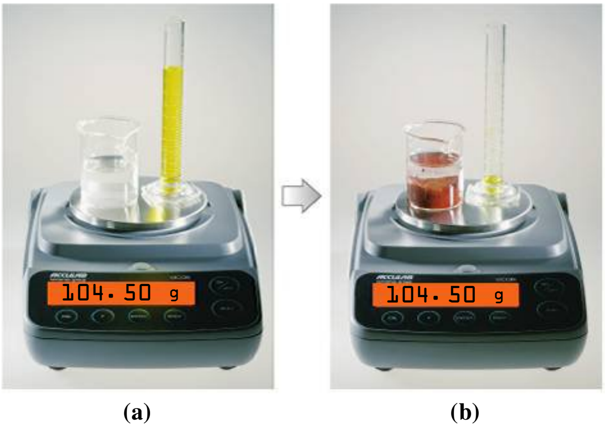
Law of Conservation of Mass

The process of combustion—burning—is so familiar that it is hard to realize what a difficult riddle it posed for early scientists. Some of the difficult-to-explain observations are described in Figure 2-1.

In 1774, Antoine Lavoisier (1743–1794) performed an experiment in which he heated a sealed glass vessel containing a sample of tin and some air. He found that the mass before heating (glass vessel + tin + air) and after heating (glass vessel + "tin calx" + remaining air) were the same. Through further experiments, he showed that the product of the reaction, tin calx (tin oxide), consisted of the original tin together with a portion of the air. Experiments like this proved to Lavoisier that oxygen from air is essential to combustion, and also led him to formulate the **law of conservation of mass**:

> The total mass of substances present after a chemical reaction is the same as the total mass of substances before the reaction.

This law is illustrated in Figure 2-2, where the reaction between silver nitrate and potassium chromate to give a red solid (silver chromate) is monitored by placing the reactants on a single-pan balance—the total mass does not change. Stated another way, the law of conservation of mass says that matter is neither created nor destroyed in a chemical reaction.



◀ FIGURE 2-2
Mass is conserved during a chemical reaction
(a) Before the reaction, a beaker with a silver nitrate solution and a graduated cylinder with a potassium chromate solution are placed on a single-pan balance, which displays their combined mass—104.50 g. **(b)** When the solutions are mixed, a chemical reaction occurs that forms silver chromate (red precipitate) in a potassium nitrate solution. Note that the total mass—104.50 g—remains unchanged.

EXAMPLE 2-1 Applying the Law of Conservation of Mass

A 0.455 g sample of magnesium is allowed to burn in 2.315 g of oxygen gas. The sole product is magnesium oxide. After the reaction, no magnesium remains and the mass of unreacted oxygen is 2.015 g. What mass of magnesium oxide is produced?

Analyze

The total mass is unchanged. The total mass is the sum of the masses of the substances present initially. The mass of magnesium oxide is the total mass minus the mass of unreacted oxygen.

Solve

First, determine the total mass before the reaction.

$$\begin{aligned}\text{mass before reaction} &= 0.455\text{ g magnesium} + 2.315\text{ g oxygen}\\ &= 2.770\text{ g mass before reaction}\end{aligned}$$

The total mass after the reaction is the same as before the reaction.

$$\begin{aligned}2.770\text{ g mass after reaction} &= ?\text{ g magnesium oxide after reaction}\\ &\quad + 2.015\text{ g oxygen after reaction}\end{aligned}$$

Solve for the mass of magnesium oxide.

$$\begin{aligned}?\text{ g magnesium oxide after reaction} &= 2.770\text{ g mass after reaction}\\ &\quad - 2.015\text{ g oxygen after reaction}\\ &= 0.755\text{ g magnesium oxide after reaction}\end{aligned}$$

Assess

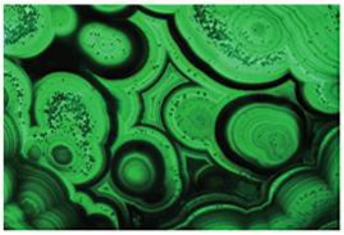
Here is another approach. The mass of oxygen that reacted is 2.315 g − 2.015 g = 0.300 g. Thus, 0.300 g oxygen combined with 0.455 g magnesium to give 0.300 g + 0.455 g = 0.755 g magnesium oxide.

PRACTICE EXAMPLE A: A 0.382 g sample of magnesium is allowed to react with 2.652 g of nitrogen gas. The sole product is magnesium nitride. After the reaction, the mass of unreacted nitrogen is 2.505 g. What mass of magnesium nitride is produced?

PRACTICE EXAMPLE B: A 7.12 g sample of magnesium is heated with 1.80 g of bromine. All the bromine is used up, and 2.07 g of magnesium bromide is the only product. What mass of magnesium remains *unreacted*?

2-1 CONCEPT ASSESSMENT

Jan Baptista van Helmont (1579–1644) weighed a young willow tree and the soil in which the tree was planted. Five years later he found that the mass of soil had decreased by only 0.057 kg, while that of the tree had increased by 75 kg. During that period he had added only water to the bucket in which the tree was planted. Helmont concluded that essentially all the mass gained by the tree had come from the water. Was this a valid conclusion? Explain.



(a)

(b)

▲ The mineral malachite **(a)** and the green patina on a copper roof **(b)** are both basic copper carbonate, just like the basic copper carbonate prepared by Proust in 1799.

Law of Constant Composition

In 1799, Joseph Proust (1754–1826) reported, "One hundred pounds of copper, dissolved in sulfuric or nitric acids and precipitated by the carbonates of soda or potash, invariably gives 180 pounds of green carbonate."* This and similar observations became the basis of the **law of constant composition**, or the **law of definite proportions**:

> All samples of a compound have the same composition—the same proportions by mass of the constituent elements.

To see how the law of constant composition works, consider the compound water. Water is made up of two atoms of hydrogen (H) for every atom of oxygen (O), a fact that can be represented symbolically by a *chemical formula*, the familiar H_2O.

---

*The substance Proust produced is actually a more complex substance called *basic* copper carbonate. Proust's results were valid because, like all compounds, basic copper carbonate has a constant composition.

The two samples described below have the same proportions of the two elements, expressed as percentages by mass. To determine the percent by mass of hydrogen, for example, simply divide the mass of hydrogen by the sample mass and multiply by 100%. For each sample, you will obtain the same result: 11.19% H.

Sample A and Its Composition		Sample B and Its Composition	
10.000 g		27.000 g	
1.119 g H	% H = 11.19	3.021 g H	% H = 11.19
8.881 g O	% O = 88.81	23.979 g O	% O = 88.81

EXAMPLE 2-2 Using the Law of Constant Composition

In Example 2-1 we found that when 0.455 g of magnesium reacted with 2.315 g of oxygen, 0.755 g of magnesium oxide was obtained. Determine the mass of magnesium contained in a 0.500 g sample of magnesium oxide.

Analyze

We know that 0.755 g of magnesium oxide contains 0.455 g of magnesium. According to the law of constant composition, the mass ratio 0.455 g magnesium/0.755 g magnesium oxide should exist in all samples of magnesium oxide.

Solve

Application of the law of constant composition gives

$$\frac{0.455\text{ g magnesium}}{0.755\text{ g magnesium oxide}} = \frac{?\text{ g magnesium}}{0.500\text{ g magnesium oxide}}$$

Solving the expression above, we obtain

$$\begin{aligned} ?\text{ g magnesium} &= 0.500\,\cancel{\text{g magnesium oxide}} \times \frac{0.455\text{ g magnesium}}{0.755\,\cancel{\text{g magnesium oxide}}} \\ &= 0.301\text{ g magnesium} \end{aligned}$$

Assess

You can also work this problem by using mass percentages. If 0.755 g of magnesium oxide contains 0.455 g of magnesium, then magnesium oxide is (0.455 g/0.755 g) × 100% = 60.3% magnesium by mass and (100% − 60.3%) = 39.7% oxygen by mass. Thus, a 0.500 g sample of magnesium oxide must contain 0.500 g × 60.3% = 0.301 g of magnesium and 0.500 g × 39.7% = 0.199 g of oxygen.

PRACTICE EXAMPLE A: What masses of magnesium and oxygen must be combined to make exactly 2.000 g of magnesium oxide?

PRACTICE EXAMPLE B: What substances are present, and what are their masses, after the reaction of 10.00 g of magnesium and 10.00 g of oxygen?

2-2 CONCEPT ASSESSMENT

When 4.15 g magnesium and 82.6 g bromine react, (1) all the magnesium is used up, (2) some bromine remains unreacted, and (3) magnesium bromide is the only product. With this information alone, is it possible to deduce the mass of magnesium bromide produced? Explain.

Dalton's Atomic Theory

From 1803 to 1808, John Dalton, an English schoolteacher, used the two fundamental laws of chemical combination just described as the basis of an atomic theory. His theory involved three assumptions:

1. Each chemical element is composed of minute, indivisible particles called atoms. Atoms can be neither created nor destroyed during a chemical change.

▲ John Dalton (1766–1844), developer of the atomic theory. Dalton has not been considered a particularly good experimenter, perhaps because of his color blindness (a condition sometimes called daltonism). However, he did skillfully use the data of others in formulating his atomic theory. (The Granger Collection)

2. All atoms of an element are alike in mass (weight) and other properties, but the atoms of one element are different from those of all other elements.
3. In each of their compounds, different elements combine in a simple numerical ratio, for example, one atom of A to one of B (AB), or one atom of A to two of B (AB_2).

If atoms of an element are indestructible (assumption 1), then the *same* atoms must be present after a chemical reaction as before. The total mass remains unchanged. Dalton's theory explains the law of conservation of mass. If all atoms of an element are alike in mass (assumption 2) and if atoms unite in *fixed* numerical ratios (assumption 3), the percent composition of a compound must have a unique value, regardless of the origin of the sample analyzed. Dalton's theory also explains the law of constant composition.

Like all good theories, Dalton's atomic theory led to a prediction—the **law of multiple proportions**.

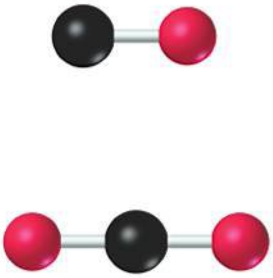
> If two elements form more than a single compound, the masses of one element combined with a fixed mass of the second are in the ratio of small whole numbers.

To illustrate, consider two oxides of carbon (an oxide is a combination of an element with oxygen). In one oxide, 1.000 g of carbon is combined with 1.333 g of oxygen, and in the other, with 2.667 g of oxygen. We see that the second oxide is richer in oxygen; in fact, it contains twice as much oxygen as the first, 2.667 g/1.333 g = 2.00. We now know that the first oxide corresponds to the formula CO and the second, CO_2 (Fig. 2-3).

KEEP IN MIND

that all we know is that the second oxide is twice as rich in oxygen as the first. If the first is CO, the possibilities for the second are CO_2, C_2O_4, C_3O_6, and so on. (See also Exercise 18.)

The characteristic relative masses of the atoms of the various elements became known as atomic weights, and throughout the nineteenth century, chemists worked at establishing reliable values of relative atomic weights. Mostly, however, chemists directed their attention to discovering new elements, synthesizing new compounds, developing techniques for analyzing materials, and in general, building up a vast body of chemical knowledge. Efforts to unravel the structure of the atom became the focus of physicists, as we see in the next several sections.

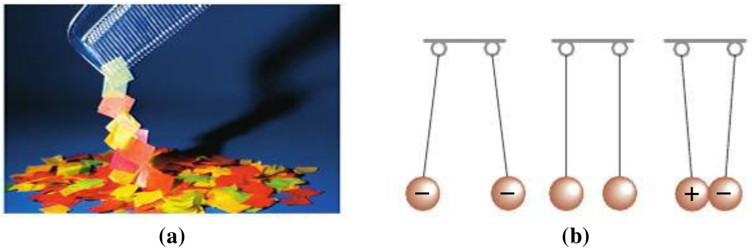


▲ FIGURE 2-3
Molecules CO and CO_2 illustrating the law of multiple proportions
The mass of carbon is the same in the two molecules, but the mass of oxygen in CO_2 is twice the mass of oxygen in CO. Thus, in accordance with the law of multiple proportions, the masses of oxygen in the two compounds, relative to a fixed mass of carbon, are in a ratio of small whole numbers, 2:1.

2-2 Electrons and Other Discoveries in Atomic Physics

Fortunately, we can acquire a qualitative understanding of atomic structure without having to retrace all the discoveries that preceded atomic physics. We do, however, need a few key ideas about the interrelated phenomena of electricity and magnetism, which we briefly discuss here. Electricity and magnetism were used in the experiments that led to the current theory of atomic structure.

Certain objects display a property called electric charge, which can be either positive (+) or negative (−). Positive and negative charges attract each other, while two positive or two negative charges repel each other. As we learn in this section, all objects of matter are made up of charged particles. An object having equal numbers of positively and negatively charged particles carries no net charge and is electrically neutral. If the number of positive charges exceeds the number of negative charges, the object has a net positive charge. If negative charges exceed positive charges, the object has a net negative charge. Sometimes when one substance is rubbed against another, as in combing hair, net electric charges build up on the objects, implying that rubbing separates

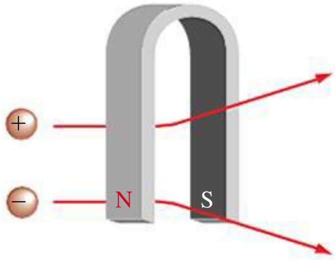


▲ FIGURE 2-4
Forces between electrically charged objects
(a) Electrostatically charged comb. If you comb your hair on a dry day, a static charge develops on the comb and causes bits of paper to be attracted to the comb. **(b)** Both objects on the left carry a negative electric charge. Objects with like charge repel each other. The objects in the center lack any electric charge and exert no forces on each other. The objects on the right carry opposite charges—one positive and one negative—and attract each other.

◀ We will use *electrostatics* (charge attractions and repulsions) to explain and understand many chemical properties.

some positive and negative charges (Fig. 2-4). Moreover, when a stationary (static) positive charge builds up in one place, a negative charge of equal size appears somewhere else; charge is balanced.

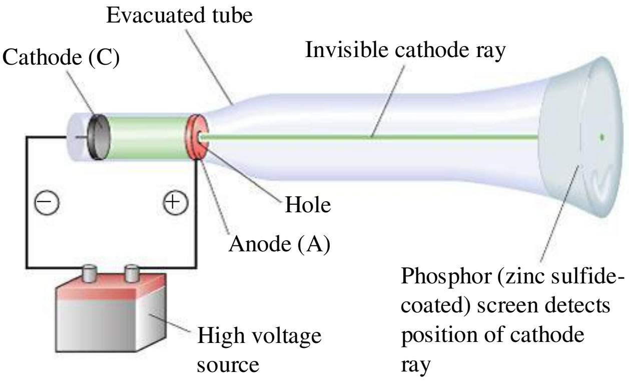
Figure 2-5 shows how charged particles behave when they move through the field of a magnet. They are deflected from their straight-line path into a curved path in a plane perpendicular to the field. Think of the field or region of influence of the magnet as represented by a series of invisible "lines of force" running from the north pole to the south pole of the magnet.



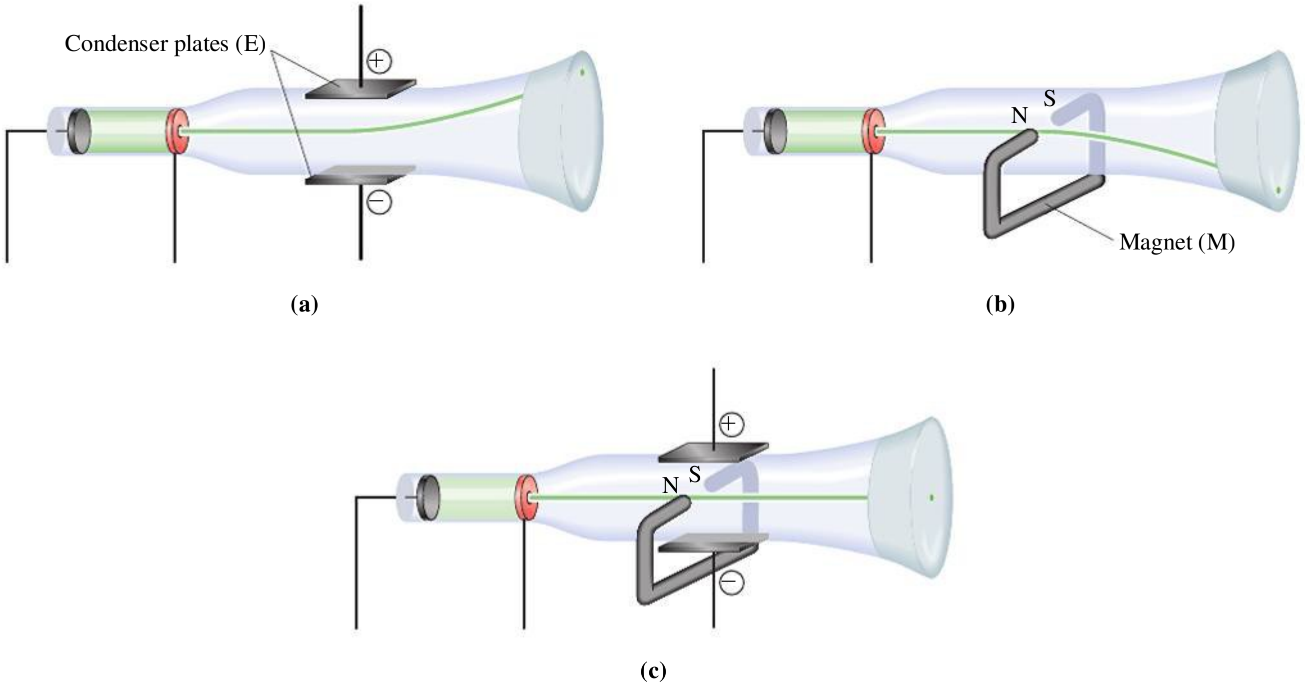
▲ FIGURE 2-5
Effect of a magnetic field on charged particles
When charged particles travel through a magnetic field so that their path is perpendicular to the field, they are deflected by the field. Negatively charged particles are deflected in one direction, and positively charged particles in the opposite direction. Several phenomena described in this section depend on this behavior.

The Discovery of Electrons

CRT, the abbreviation for cathode-ray tube, was once a familiar acronym. Before liquid crystal display (LCD) was available, the CRT was the heart of computer monitors and TV sets. The first cathode-ray tube was made by Michael Faraday (1791–1867) about 150 years ago. When he passed electricity through glass tubes from which most of the air had been evacuated, Faraday discovered **cathode rays**, a type of radiation emitted by the negative terminal, or *cathode*. The radiation crossed the evacuated tube to the positive terminal, or *anode*. Later scientists found that cathode rays travel in straight lines and have properties that are independent of the cathode material (that is, whether it is iron, platinum, and so on). The construction of a CRT is shown in Figure 2-6. The cathode rays produced in the CRT are invisible, and they can be detected only by the light emitted by materials that they strike. These materials, called *phosphors*, are painted on the end of the CRT so that the path of the cathode rays can be revealed. (*Fluorescence* is the term used to describe the emission of light by a phosphor when it is struck by



◀ FIGURE 2-6
A cathode-ray tube
The high-voltage source of electricity creates a negative charge on the electrode at the left (cathode) and a positive charge on the electrode at the right (anode). Cathode rays pass from the cathode (C) to the anode (A), which is perforated to allow the passage of a narrow beam of cathode rays. The rays are visible only through the green fluorescence that they produce on the zinc sulfide–coated screen at the end of the tube. They are invisible in other parts of the tube.



▲ FIGURE 2-7
Cathode rays and their properties
(a) Deflection of cathode rays in an electric field. The beam of cathode rays is deflected as it travels from left to right in the field of the electrically charged condenser plates (E). The deflection corresponds to that expected of negatively charged particles.
(b) Deflection of cathode rays in a magnetic field. The beam of cathode rays is deflected as it travels from left to right in the field of the magnet (M). The deflection corresponds to that expected of negatively charged particles. **(c)** Determining the mass-to-charge ratio, m/e, for cathode rays. The cathode-ray beam strikes the end screen undeflected if the forces exerted on it by the electric and magnetic fields are counterbalanced. By knowing the strengths of the electric and magnetic fields, together with other data, a value of m/e can be obtained. Precise measurements yield a value of -5.6857×10^{-9} g per coulomb. (Because cathode rays carry a negative charge, the sign of the mass-to-charge ratio is also negative.)

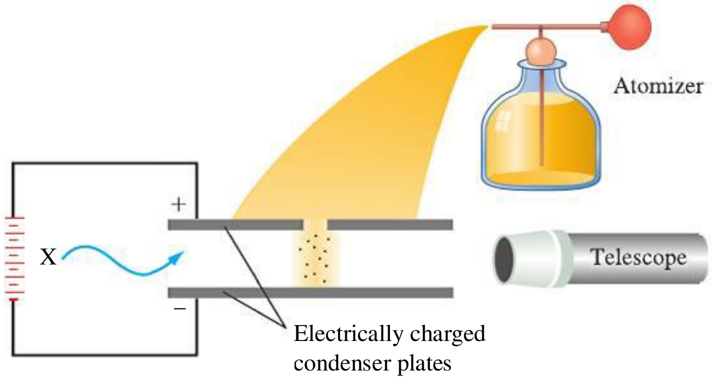
energetic radiation.) Another significant observation about cathode rays is that they are deflected by electric and magnetic fields in the manner expected for negatively charged particles (Fig. 2-7a, b).

In 1897, by the method outlined in Figure 2-7(c), J. J. Thomson (1856–1940) established the ratio of mass (m) to electric charge (e) for cathode rays, that is, m/e. Also, Thomson concluded that cathode rays are negatively charged *fundamental* particles of matter found in all atoms. (The properties of cathode rays are *independent* of the composition of the cathode.) Cathode rays subsequently became known as **electrons**, a term first proposed by George Stoney in 1874.

Robert Millikan (1868–1953) determined the electronic charge e through a series of oil-drop experiments (1906–1914), described in Figure 2-8. The currently accepted value of the electronic charge e, expressed in coulombs to five significant figures, is -1.6022×10^{-19} C. By combining this value with an accurate value of the mass-to-charge ratio for an electron, we find that the mass of an electron is 9.1094×10^{-28} g.

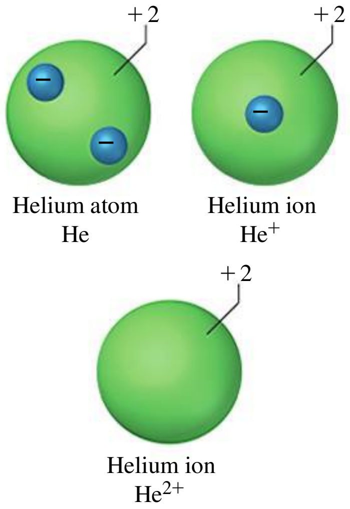
▶ The coulomb (C) is the SI unit of electric charge (see also Appendix B).

Once the electron was seen to be a fundamental particle of matter found in all atoms, atomic physicists began to speculate on how these particles were incorporated into atoms. The commonly accepted model was that proposed by J. J. Thomson. Thomson thought that the positive charge necessary to counterbalance the negative charges of electrons in a neutral atom was in the form of



◀ FIGURE 2-8
Millikan's oil-drop experiment
Ions (charged atoms or molecules) are produced by energetic radiation, such as X-rays (X). Some of these ions become attached to oil droplets, giving them a net charge. The fall of a droplet in the electric field between the condenser plates is speeded up or slowed down, depending on the magnitude and sign of the charge on the droplet. By analyzing data from a large number of droplets, Millikan concluded that the magnitude of the charge, q, on a droplet is an *integral* multiple of the electric charge, e. That is, $q = ne$ (where $n = 1, 2, 3, \ldots$).

a nebulous cloud. Electrons, he suggested, floated in a diffuse cloud of positive charge (rather like a lump of gelatin with electron "fruit" embedded in it). This model became known as the plum-pudding model because of its similarity to a popular English dessert. The plum-pudding model is illustrated in Figure 2-9 for a neutral atom and for atomic species, called *ions*, which carry a net charge.



▲ FIGURE 2-9
The plum-pudding atomic model
According to this model, a helium atom would have a +2 cloud of positive charge and two electrons (−2). If a helium atom loses one electron, it becomes charged and is called an *ion*. This ion, referred to as He^{+}, has a net charge of 1+. If the helium atom loses both electrons, the He^{2+} ion forms.

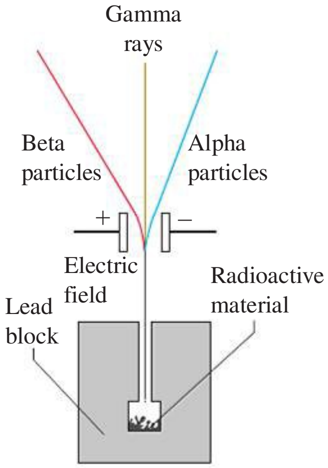
X-Rays and Radioactivity

Cathode-ray research had many important spin-offs. In particular, two natural phenomena of immense theoretical and practical significance were discovered in the course of other investigations.

In 1895, Wilhelm Roentgen (1845–1923) noticed that when cathode-ray tubes were operating, certain materials *outside* the tubes glowed or fluoresced. He showed that this fluorescence was caused by radiation emitted by the cathode-ray tubes. Because of the unknown nature of this radiation, Roentgen coined the term *X-ray*. We now recognize the X-ray as a form of high-energy electromagnetic radiation, which is discussed in Chapter 8.

Antoine Henri Becquerel (1852–1908) associated X-rays with fluorescence and wondered if naturally fluorescent materials produce X-rays. To test this idea, he wrapped a photographic plate with black paper, placed a coin on the paper, covered the coin with a uranium-containing fluorescent material, and exposed the entire assembly to sunlight. When he developed the film, a clear image of the coin could be seen. The fluorescent material had emitted radiation (presumably X-rays) that penetrated the paper and exposed the film. On one occasion, because the sky was overcast, Becquerel placed the experimental assembly inside a desk drawer for a few days while waiting for the weather to clear. On resuming the experiment, Becquerel decided to replace the original photographic film, expecting that it may have become slightly exposed. He developed the original film and found that instead of the expected feeble image, there was a very sharp one. The film had become strongly exposed because the uranium-containing material had emitted radiation continuously, even when it was not fluorescing. Becquerel had discovered **radioactivity**.

Ernest Rutherford (1871–1937) identified two types of radiation from radioactive materials, alpha (α) and beta (β). **Alpha particles** carry two fundamental units of positive charge and have essentially the same mass as helium atoms. In fact, alpha particles are identical to He^{2+} ions. **Beta particles** are negatively charged particles produced by changes occurring within the nuclei of radioactive atoms and have the same properties as electrons. A third form of radiation, which is not affected by electric or magnetic fields, was discovered in 1900 by Paul Villard. This radiation, called **gamma rays** (γ),



▲ FIGURE 2-10
Three types of radiation from radioactive materials
The radioactive material is enclosed in a lead block. All the radiation except that passing through the narrow opening is absorbed by the lead. When the escaping radiation is passed through an electric field, it splits into three beams. One beam is undeflected—these are gamma (γ) rays. A second beam is attracted to the negatively charged plate. These are the positively charged alpha (α) particles. The third beam, of negatively charged beta (β) particles, is deflected toward the positive plate.

is not made up of particles; it is electromagnetic radiation of extremely high penetrating power. These three forms of radioactivity are illustrated in Figure 2-10.

By the early 1900s, additional radioactive elements were discovered, principally by Marie and Pierre Curie. Rutherford and Frederick Soddy made another profound finding: The chemical properties of a radioactive element *change* as it undergoes radioactive decay. This observation suggests that radioactivity involves fundamental changes at the *subatomic* level—in radioactive decay, one element is changed into another, a process known as *transmutation*.

2-3 The Nuclear Atom

In 1909, Rutherford, with his assistant Hans Geiger, began a line of research using α particles as probes to study the inner structure of atoms. Based on Thomson's plum-pudding model, Rutherford expected that most particles in a beam of α particles would pass through thin sections of matter largely undeflected, but that some α particles would be slightly scattered or deflected as they encountered electrons. By studying these scattering patterns, he hoped to deduce something about the distribution of electrons in atoms.

The apparatus used for these studies is pictured in Figure 2-11. Alpha particles were detected by the flashes of light they produced when they struck a zinc sulfide screen mounted on the end of a telescope. When Geiger and Ernst Marsden, a student, bombarded very thin foils of gold with α particles, they observed the following:

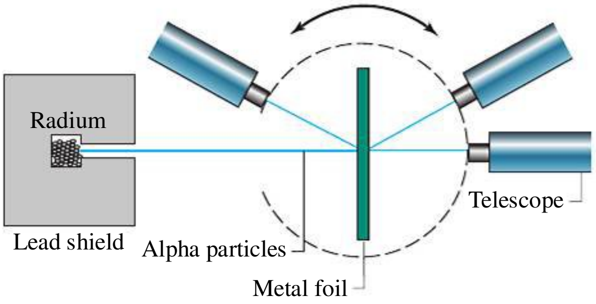
- The majority of α particles penetrated the foil undeflected.
- Some α particles experienced slight deflections.
- A few (about 1 in every 20,000) suffered rather serious deflections as they penetrated the foil.
- A similar number did not pass through the foil at all, but bounced back in the direction from which they had come.

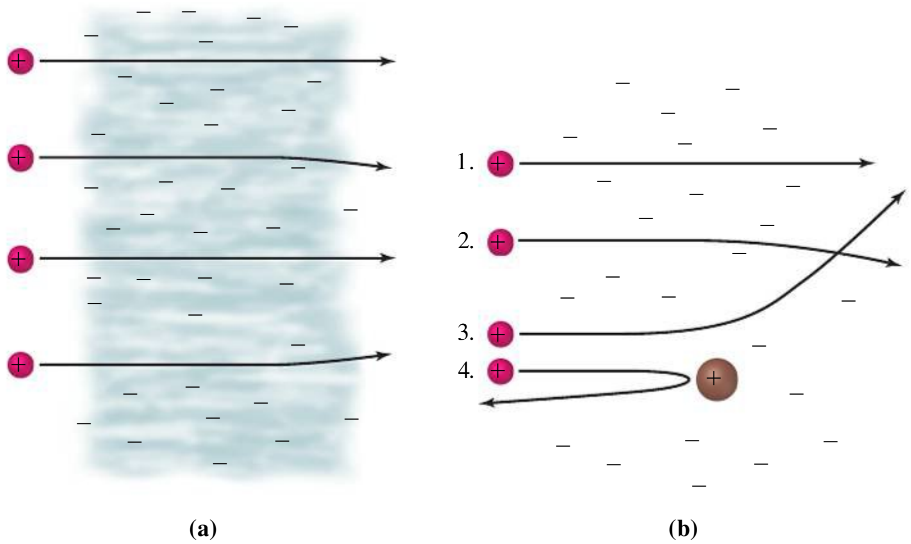
The large-angle scattering greatly puzzled Rutherford. As he commented some years later, this observation was "about as credible as if you had fired a 15-inch shell at a piece of tissue paper and it came back and hit you." By 1911, though, Rutherford had an explanation. He based his explanation on a model of the atom known as the *nuclear atom* and having these features:

1. Most of the mass and all of the positive charge of an atom are centered in a very small region called the *nucleus*. The remainder of the atom is mostly *empty space*.
2. The magnitude of the positive charge is different for different atoms and is approximately one-half the atomic weight of the element.
3. There are as many electrons outside the nucleus as there are units of positive charge on the nucleus. The atom as a whole is electrically neutral.

▶ Perhaps because he found it tedious to sit in the dark and count spots of light on a zinc sulfide screen, Geiger was motivated to develop an automatic radiation detector. The result was the well-known Geiger counter.

▶ FIGURE 2-11
The scattering of α particles by metal foil
The telescope travels in a circular track around an evacuated chamber containing the metal foil. Most α particles pass through the metal foil undeflected, but some are deflected through large angles.





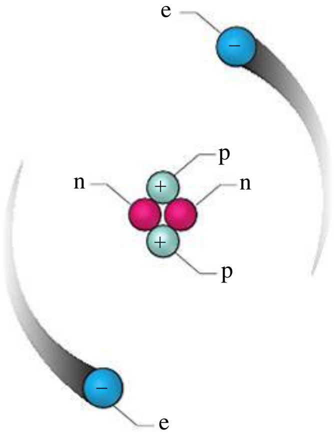
▲ FIGURE 2-12
Explaining the results of α-particle scattering experiments
(a) Rutherford's expectation was that small, positively charged α particles should pass through the nebulous, positively charged cloud of the Thomson plum-pudding model largely undeflected. Some would be slightly deflected by passing near electrons (present to neutralize the positive charge of the cloud). **(b)** Rutherford's explanation was based on a nuclear atom. With an atomic model having a small, dense, positively charged nucleus and extranuclear electrons, we would expect the four different types of paths actually observed:

1. undeflected straight-line paths exhibited by most of the α particles
2. slight deflections of α particles passing close to electrons
3. severe deflections of α particles passing close to a nucleus
4. reflections from the foil of α particles approaching a nucleus head-on

Rutherford's initial expectation and his explanation of the α-particle experiments are described in Figure 2-12.

Discovery of Protons and Neutrons

Rutherford's nuclear atom suggested the existence of positively charged fundamental particles of matter in the nuclei of atoms. Rutherford himself discovered these particles, called **protons**, in 1919 in studies involving the scattering of α particles by nitrogen atoms in air. The protons were freed as a result of collisions between α particles and the nuclei of nitrogen atoms. At about this same time, Rutherford predicted the existence in the nucleus of electrically neutral fundamental particles. In 1932, James Chadwick showed that a newly discovered penetrating radiation consisted of beams of *neutral* particles. These particles, called **neutrons**, originated from the nuclei of atoms. Thus, it has been only for about the past 100 years that we have had the atomic model suggested by Figure 2-13.



▲ FIGURE 2-13
The nuclear atom—illustrated by the helium atom
In this drawing, electrons are shown much closer to the nucleus than is the case. The actual situation is more like this: If the entire atom were represented by a room, 5 m × 5 m × 5 m, the nucleus would occupy only about as much space as the period at the end of this sentence.

2-3 CONCEPT ASSESSMENT

In light of information presented to this point in the text, explain which of the three assumptions of Dalton's atomic theory (page 37) can still be considered correct and which cannot.

TABLE 2.1 Properties of Three Fundamental Particles

	Electric Charge		Mass	
	SI (C)	Atomic	SI (g)	Atomic (u)[a]
Proton	$+1.6022 \times 10^{-19}$	$+1$	1.6726×10^{-24}	1.0073
Neutron	0	0	1.6749×10^{-24}	1.0087
Electron	-1.6022×10^{-19}	-1	9.1094×10^{-28}	0.00054858

[a] u is the SI symbol for atomic mass unit (abbreviated as amu).

▶ The masses of the proton and neutron are different in the fourth significant figure. The charges of the proton and electron, however, are believed to be exactly equal in magnitude (but opposite in sign). The charges and masses are known much more precisely than suggested here. More precise values are given on the inside back cover.

Properties of Protons, Neutrons, and Electrons

The number of protons in a given atom is called the **atomic number**, or the **proton number, *Z***. The number of electrons in the atom is also equal to Z because the atom is electrically neutral. The total number of protons and neutrons in an atom is called the **mass number, *A***. The number of neutrons, the **neutron number**, is $A - Z$. An electron carries an atomic unit of negative charge, a proton carries an atomic unit of positive charge, and a neutron is electrically neutral. Table 2.1 presents the charges and masses of protons, neutrons, and electrons in two ways.

The **atomic mass unit** (described more fully on page 46) is defined as exactly 1/12 of the mass of the atom known as carbon-12 (read as carbon twelve). An atomic mass unit is abbreviated as amu and denoted by the symbol u. As we see from Table 2.1, the proton and neutron masses are just slightly greater than 1 u. By comparison, the mass of an electron is only about 1/2000th the mass of the proton or neutron.

The three subatomic particles considered in this section are the only ones involved in the phenomena of interest to us in this text. You should be aware, however, that a study of matter at its most fundamental level must consider many additional subatomic particles. The electron is believed to be a truly fundamental particle. However, modern particle physics now considers the neutron and proton to be composed of other, more fundamental particles.

2-4 Chemical Elements

Now that we have acquired some fundamental ideas about atomic structure, we can more thoroughly discuss the concept of chemical elements.

All atoms of a particular element have the same atomic number, Z, and, conversely, all atoms with the same number of protons are atoms of the same element. The elements shown on the inside front cover have atomic numbers from $Z = 1$ to $Z = 112$. Each element has a name and a distinctive symbol. **Chemical symbols** are one- or two-letter abbreviations of the name (usually the English name). The first (but never the second) letter of the symbol is capitalized; for example: carbon, C; oxygen, O; neon, Ne; and silicon, Si. Some elements known since ancient times have symbols based on their Latin names, such as Fe for iron (*ferrum*) and Pb for lead (*plumbum*). The element sodium has the symbol Na, based on the Latin *natrium* for sodium carbonate. Potassium has the symbol K, based on the Latin *kalium* for potassium carbonate. The symbol for tungsten, W, is based on the German *wolfram*.

▶ The discovery of element 112 has recently been authenticated by IUPAC. However, element 112 has not yet been given a name or symbol.

▶ Other atomic symbols not based on English names include Cu, Ag, Sn, Sb, Au, and Hg.

Elements beyond uranium ($Z = 92$) do not occur naturally and must be synthesized in particle accelerators (described in Chapter 25). Elements of the very highest atomic numbers have been produced only on a limited number of occasions, a few atoms at a time. Inevitably, controversies have arisen about which research team discovered a new element and, in fact, whether a discovery was made at all. However, international agreement has been reached on the first 112 elements; each one, except element 112, has an official name and symbol.

Isotopes

To represent the composition of any particular atom, we need to specify its number of protons (p), neutrons (n), and electrons (e). We can do this with the symbolism

$$\begin{tikzcd} \text{number p + number n} \arrow[dr] & & \\ & {}^{A}_{Z}\text{E} & \text{symbol of element} \arrow[l] \\ \text{number p} \arrow[ur] & & \end{tikzcd} \tag{2.1}$$

This symbolism indicates that the atom is element E and that it has atomic number Z and mass number A. For example, an atom of aluminum represented as ${}^{27}_{13}\text{Al}$ has 13 protons and 14 neutrons in its nucleus and 13 electrons outside the nucleus. (Recall that an atom has the same number of electrons as protons.)

Contrary to what Dalton thought, we now know that atoms of an element do not necessarily all have the same mass. In 1912, J. J. Thomson measured the mass-to-charge ratios of positive ions formed from neon atoms. From these ratios he deduced that about 91% of the atoms had one mass and that the remaining atoms were about 10% heavier. All neon atoms have 10 protons in their nuclei, and most have 10 neutrons as well. A very few neon atoms, however, have 11 neutrons and some have 12. We can represent these three different types of neon atoms as

$${}^{20}_{10}\text{Ne} \qquad {}^{21}_{10}\text{Ne} \qquad {}^{22}_{10}\text{Ne}$$

◀ Because neon is the only element with $Z = 10$, the symbols ${}^{20}\text{Ne}$, ${}^{21}\text{Ne}$, and ${}^{22}\text{Ne}$ convey the same meaning as ${}^{20}_{10}\text{Ne}$, ${}^{21}_{10}\text{Ne}$, and ${}^{22}_{10}\text{Ne}$.

◀ Odd-numbered elements tend to have fewer isotopes than do even-numbered elements. Section 25-7 will explain why.

Atoms that have the *same* atomic number (Z) but *different* mass numbers (A) are called **isotopes**. Of all Ne atoms on Earth, 90.51% are ${}^{20}_{10}\text{Ne}$. The percentages of ${}^{21}_{10}\text{Ne}$ and ${}^{22}_{10}\text{Ne}$ are 0.27% and 9.22%, respectively. These percentages—90.51%, 0.27%, 9.22%—are the **percent natural abundances** of the three neon isotopes. Sometimes the mass numbers of isotopes are incorporated into the names of elements, such as neon-20 (neon twenty). Percent natural abundances are always based on *numbers*, not masses. Thus, 9051 of every 10,000 neon atoms are neon-20 atoms. Some elements, as they exist in nature, consist of just a single type of atom and therefore do not have naturally occurring isotopes.* Aluminum, for example, consists only of aluminum-27 atoms.

◀ Usually all the isotopes of an element share the same name and atomic symbol. The exception is hydrogen. Isotope ${}^{2}_{1}\text{H}$ is called deuterium (symbol D), and ${}^{3}_{1}\text{H}$ is tritium (T).

Ions

When atoms lose or gain electrons, for example, in the course of a chemical reaction, the species formed are called **ions** and carry net charges. Because an electron is negatively charged, adding electrons to an electrically neutral atom produces a negatively charged ion. Removing electrons results in a positively charged ion. The number of protons does not change when an atom becomes an ion. For example, ${}^{20}\text{Ne}^{+}$ and ${}^{22}\text{Ne}^{2+}$ are ions. The first one has 10 protons, 10 neutrons, and *9* electrons. The second one also has 10 protons, but 12 neutrons and *8* electrons. The charge on an ion is equal to the number of protons *minus* the number of electrons. That is

$$\begin{tikzcd} \text{number p + number n} \arrow[dr] & & \\ & {}^{A}_{Z}\text{E}^{\#\pm} & \text{number p} - \text{number e} \arrow[l, bend right] \\ \text{number p} \arrow[ur] & & \end{tikzcd} \tag{2.2}$$

◀ In this expression, #± indicates that the charge is written with the number (#) *before* the + or − sign. However, when the charge is 1+ or 1−, the number 1 is not included.

Another example is the ${}^{16}\text{O}^{2-}$ ion. In this ion, there are 8 protons (atomic number 8), 8 neutrons (mass number − atomic number), and *10* electrons ($8 - 10 = -2$).

---

*__Nuclide__ is the general term used to describe an atom with a particular atomic number and mass number. Although there are several elements with only one naturally occurring nuclide, it is possible to produce additional nuclides of these elements—isotopes—by artificial means (Section 25-3). The artificial isotopes are radioactive, however. In all, the number of synthetic isotopes exceeds the number of naturally occurring ones by several fold.

EXAMPLE 2-3 Relating the Numbers of Protons, Neutrons, and Electrons in Atoms and Ions

Through an appropriate symbol, indicate the number of protons, neutrons, and electrons in **(a)** an atom of barium-135 and **(b)** the double negatively charged ion of selenium-80.

Analyze

Given the name of an element, we can find the symbol and the atomic number, Z, for that element from a list of elements or a periodic table. To determine the number of protons, neutrons, and electrons, we make use of the following relationships:

$$Z = \text{number p} \qquad A = \text{number p} + \text{number n} \qquad \text{charge} = \text{number p} - \text{number e}$$

The relationships above are summarized in expression (2.2).

Solve

(a) We are given the name (barium) and the mass number of the atom (135). From a list of the elements or a periodic table we obtain the symbol (Ba) and the atomic number $(Z = 56)$, leading to the symbolic representation

$${}^{135}_{56}\text{Ba}$$

From this symbol one can deduce that the neutral atom has 56 protons; a neutron number of $A - Z = 135 - 56 = 79$ neutrons; and a number of electrons equal to Z, that is, 56 electrons.

(b) We are given the name (selenium) and the mass number of the ion (80). From a list of the elements or a periodic table we obtain the symbol (Se) and the atomic number (34). Together with the fact that the ion carries a charge of 2−, we have the data required to write the symbol

$${}^{80}_{34}\text{Se}^{2-}$$

From this symbol, we can deduce that the ion has 34 protons; a neutron number of $A - Z = 80 - 34 = 46$ neutrons; and 36 electrons, leading to a net charge of $+34 - 36 = -2$.

Assess

When writing the symbol for a particular atom or ion, we often omit the atomic number. For example, for ${}^{135}_{56}\text{Ba}$ and ${}^{80}_{34}\text{Se}^{2-}$, we often use the simpler representations ${}^{135}\text{Ba}$ and ${}^{80}\text{Se}^{2-}$.

PRACTICE EXAMPLE A: Use the notation ${}^{A}_{Z}E$ to represent the isotope of silver having a neutron number of 62.

PRACTICE EXAMPLE B: Use the notation ${}^{A}_{Z}E$ to represent a tin ion having the same number of electrons as an atom of the isotope cadmium-112. Explain why there can be more than one answer.

2-4 CONCEPT ASSESSMENT

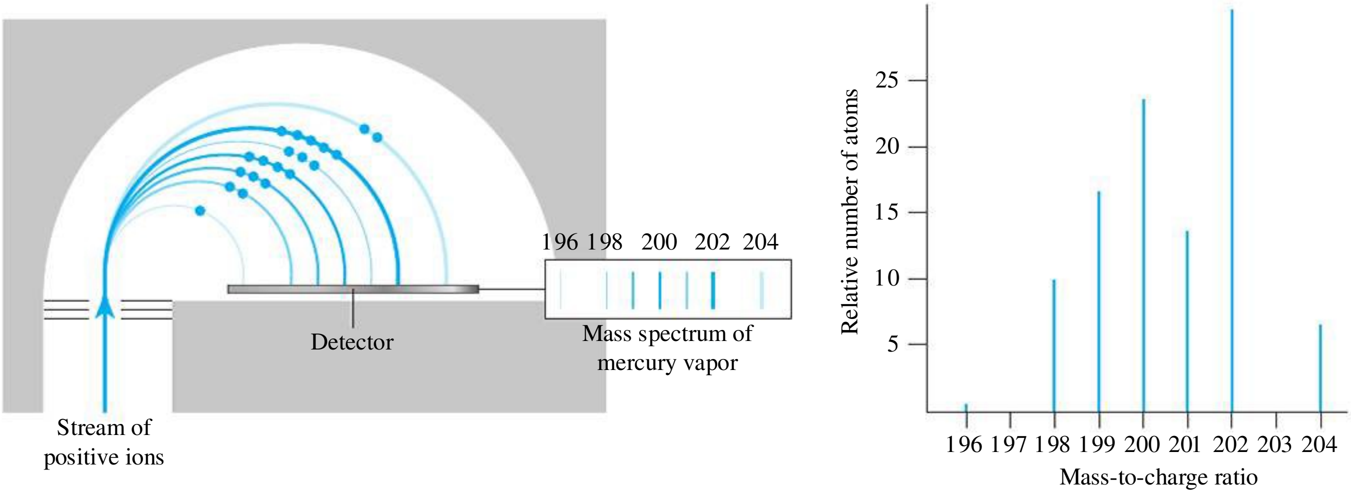
What is the single exception to the statement that all atoms comprise protons, neutrons, and electrons?

Isotopic Masses

We cannot determine the mass of an individual atom just by adding up the masses of its fundamental particles. When protons and neutrons combine to form a nucleus, a very small portion of their original mass is converted to energy and released. However, we cannot predict exactly how much this so-called nuclear binding energy will be. Determining the masses of individual atoms, then, is something that must be done by experiment, in the following way. By international agreement, one type of atom has been chosen and assigned a specific mass. This standard is an atom of the isotope carbon-12, which is assigned a mass of exactly 12 atomic mass units, that is, 12 u. Next, the masses of other atoms relative to carbon-12 are determined with a **mass spectrometer**. In this device, a beam of gaseous ions passing through electric and magnetic fields separates into components of differing masses. The

▶ Ordinarily we expect like-charged objects (such as protons) to repel each other. The forces holding protons and neutrons together in the nucleus are very much stronger than ordinary electrical forces (Section 25-6).

▶ This definition also establishes that one atomic mass unit (1 u) is *exactly* 1/12 the mass of a carbon-12 atom.



▲ FIGURE 2-14

A mass spectrometer and mass spectrum

In this mass spectrometer, a gaseous sample is ionized by bombardment with electrons in the lower part of the apparatus (not shown). The positive ions thus formed are subjected to an electrical force by the electrically charged velocity selector plates and a magnetic force by a magnetic field perpendicular to the page. Only ions with a particular velocity pass through and are deflected into circular paths by the magnetic field. Ions with different masses strike the detector (here a photographic plate) in different regions. The more ions of a given type, the greater the response of the detector (intensity of line on the photographic plate). In the mass spectrum shown for mercury, the response of the ion detector (intensity of lines on photographic plate) has been converted to a scale of relative numbers of atoms. The percent natural abundances of the mercury isotopes are ^{196}Hg, 0.146%; ^{198}Hg, 10.02%; ^{199}Hg, 16.84%; ^{200}Hg, 23.13%; ^{201}Hg, 13.22%; ^{202}Hg, 29.80%; and ^{204}Hg, 6.85%.

separated ions are focused on a measuring instrument, which records their presence and amounts. Figure 2-14 illustrates mass spectrometry and a typical mass spectrum.

Although mass numbers are whole numbers, the actual masses of individual atoms (in atomic mass units, u) are never whole numbers, except for carbon-12. However, they are very close in value to the corresponding mass numbers, as we can see for the isotope oxygen-16. From mass spectral data the ratio of the mass of ^{16}O to ^{12}C is found to be 1.33291. Thus, the mass of the oxygen-16 atom is

$$1.33291 \times 12\ \text{u} = 15.9949\ \text{u}$$

which is very nearly equal to the mass number of 16.

◀ The primary standard for atomic masses has evolved over time. For example, Dalton originally assigned H a mass of 1 u. Later, chemists took naturally occurring oxygen at 16 u to be the definition of the atomic-weight scale. Concurrently, physicists defined the oxygen-16 isotope as 16 u. This resulted in conflicting values. In 1971 the adoption of carbon-12 as the universal standard resolved this disparity.

EXAMPLE 2-4 Establishing Isotopic Masses by Mass Spectrometry

With mass spectral data, the mass of an oxygen-16 atom is found to be 1.06632 times that of a nitrogen-15 atom. Given that ^{16}O has a mass of 15.9949 u (see above), what is the mass of a nitrogen-15 atom, in u?

Analyze

Given the ratio (mass of ^{16}O)/(mass of ^{15}N) = 1.06632 and the mass of ^{16}O, 15.9949 u, we solve for the mass of ^{15}N.

Solve

We know that

$$\frac{\text{mass of }^{16}\text{O}}{\text{mass of }^{15}\text{N}} = 1.06632$$

(continued)

We solve the expression above for the mass of ^{15}N and then substitute 15.9949 u for the mass of ^{16}O. We obtain the result

$$\text{mass of } ^{15}\text{N} = \frac{\text{mass of } ^{16}\text{O}}{1.06632} = \frac{15.9949 \text{ u}}{1.06632} = 15.0001 \text{ u}$$

Assess

The mass of ^{15}N is very nearly 15, as we should expect. If we had mistakenly multiplied instead of dividing by the ratio 1.06632, the result would have been slightly larger than 16 and clearly incorrect.

PRACTICE EXAMPLE A: What is the ratio of masses for $^{202}Hg/^{12}C$, if the isotopic mass for ^{202}Hg is 201.97062 u?

PRACTICE EXAMPLE B: An isotope with atomic number 64 and mass number 158 is found to have a mass ratio relative to that of carbon-12 of 13.16034. What is the isotope, what is its atomic mass in u, and what is its mass relative to oxygen-16?

2-5 Atomic Mass

In a table of atomic masses, the value listed for carbon is 12.0107, yet the atomic mass standard is *exactly* 12. Why the difference? The atomic mass standard is based on a sample of carbon containing only atoms of carbon-12, whereas naturally occurring carbon contains some carbon-13 atoms as well. The existence of these two isotopes causes the observed atomic mass to be greater than 12. The **atomic mass (weight)*** of an element is the average of the isotopic masses, *weighted* according to the naturally occurring abundances of the isotopes of the element. In a weighted average, we must assign greater importance—give greater weight—to the quantity that occurs more frequently. Since carbon-12 atoms are much more abundant than carbon-13, the weighted average must lie much closer to 12 than to 13. This is the result that we get by applying the following general equation, where the right-hand side of the equation includes one term for each naturally occurring isotope.

▶ Carbon-14, used for radiocarbon dating, is formed in the upper atmosphere. The amount of carbon-14 on Earth is too small to affect the atomic mass of carbon.

KEEP IN MIND

that the fractional abundance is the percent abundance divided by 100%. Thus, a 98.93% abundance is a 0.9893 abundance.

$$\begin{matrix}\text{at. mass}\\ \text{of an}\\ \text{element}\end{matrix} = \left(\begin{matrix}\text{fractional}\\ \text{abundance of}\\ \text{isotope 1}\end{matrix} \times \begin{matrix}\text{mass of}\\ \text{isotope 1}\end{matrix}\right) + \left(\begin{matrix}\text{fractional}\\ \text{abundance of}\\ \text{isotope 2}\end{matrix} \times \begin{matrix}\text{mass of}\\ \text{isotope 2}\end{matrix}\right) + \dots \quad \textbf{(2.3)}$$

The first term on the right side of equation (2.3) represents the contribution from isotope 1; the second term represents the contribution from isotope 2; and so on.

We will use equation (2.3), with appropriate data, in Example 2-6, but first let us illustrate the ideas of fractional abundance and a weighted average in a different way in establishing the atomic mass of naturally occurring carbon. The mass spectrum of carbon shows that 98.93% of carbon atoms are carbon-12 with a mass of exactly 12 u; the rest are carbon-13 atoms with a mass of 13.0033548378 u. Therefore:

$$\begin{aligned}\begin{matrix}\text{at. mass of naturally}\\ \text{occurring carbon}\end{matrix} &= 0.9893 \times 12 \text{ u} + (1 - 0.9893) \times 13.0033548378 \text{ u}\\ &= 13.0033548378 \text{ u} - 0.9893 \times (13.0033548378 \text{ u} - 12 \text{ u})\\ &= 13.0033548378 \text{ u} - 0.9893 \times (1.0033548378 \text{ u})\\ &= 13.0033548378 \text{ u} - 0.9893\\ &= 12.0107 \text{ u}\end{aligned}$$

---

*Since Dalton's time, atomic masses have been called atomic weights. They still are by most chemists, yet what we are describing here is mass, not weight. Old habits die hard.

It is important to note that, in the setup above, 12 u and the "1" appearing in the factor (1 − 0.9893) are exact numbers. Thus, by applying the rules for significant figures (see Chapter 1), the atomic mass of carbon can be reported with four decimal places.

To determine the atomic mass of an element having three naturally occurring isotopes, such as potassium, we would have to include three contributions in the weighted average, and so on.

The percent natural abundances of most of the elements remain very nearly constant from one sample of matter to another. For example, the proportions of ^{12}C and ^{13}C atoms are the same in samples of pure carbon (diamond), carbon dioxide gas, and a mineral form of calcium carbonate (calcite). We can treat all natural carbon-containing materials as if there were a single *hypothetical* type of carbon atom with a mass of 12.0107 u. This means that once weighted-average atomic masses have been determined and tabulated, we can simply use these values in calculations requiring atomic masses.

Sometimes a qualitative understanding of the relationship between isotopic masses, percent natural abundances, and weighted-average atomic mass is all that we need, and no calculation is necessary, as illustrated in Example 2-5. Example 2-6 and the accompanying Practice Examples provide additional applications of equation (2.3).

The table of atomic masses (inside the front cover) shows that some atomic masses are stated more precisely than others. For example, the atomic mass of F is given as 18.9984 u and that of Kr is given as 83.798 u. In fact, the atomic mass of fluorine is known even more precisely (18.9984032 u); the value of 18.9984 u has been rounded off to six significant figures. Why is the atomic mass of F known so much more precisely than that of Kr? Only one type of fluorine atom occurs naturally: fluorine-19. Determining the atomic mass of

EXAMPLE 2-5 Understanding the Meaning of a Weighted-Average Atomic Mass

The two naturally occurring isotopes of lithium, lithium-6 and lithium-7, have masses of 6.01512 u and 7.01600 u, respectively. Which of these two occurs in greater abundance?

Analyze

Look up the atomic mass of Li and compare it with the masses of ^{6}Li and ^{7}Li. If the atomic mass of Li is closer to that of ^{6}Li, then ^{6}Li is the more abundant isotope. If the atomic mass of Li is closer to that of ^{7}Li, then ^{7}Li is the more abundant isotope.

Solve

From a table of atomic masses (inside the front cover), we see that the atomic mass of lithium is 6.941 u. Because this value—a weighted-average atomic mass—is much closer to 7.01600 u than to 6.01512 u, lithium-7 must be the more abundant isotope.

Assess

Atomic masses of specific isotopes can be determined very precisely. The values given above for ^{6}Li and ^{7}Li have been rounded to five decimal places. The precise values are 6.015122795 u and 7.01600455 u.

PRACTICE EXAMPLE A: The two naturally occurring isotopes of boron, boron-10 and boron-11, have masses of 10.0129370 u and 11.0093054 u, respectively. Which of these two occurs in greater abundance?

PRACTICE EXAMPLE B: Indium has two naturally occurring isotopes and a weighted atomic mass of 114.818 u. One of the isotopes has a mass of 112.904058 u. Which of the following must be the second isotope: ^{111}In, ^{112}In, ^{114}In, or ^{115}In? Which of the two naturally occurring isotopes must be the more abundant?

EXAMPLE 2-6 Relating the Masses and Natural Abundances of Isotopes to the Atomic Mass of an Element

Bromine has two naturally occurring isotopes. One of them, bromine-79, has a mass of 78.9183 u and an abundance of 50.69%. What must be the mass and percent natural abundance of the other, bromine-81?

Analyze

Although the atomic mass of Br is not given explicitly, it is a known quantity. From the inside front cover, we find that the atomic mass of Br is 79.904 u. We need to apply two key concepts: (1) the atomic mass of Br is a weighted average of the masses of ^{79}Br and ^{81}Br, and (2) the percent natural abundances of ^{79}Br and ^{81}Br must add up to 100%.

Solve

The atomic mass of Br is a weighted average of the masses of ^{79}Br and ^{81}Br:

$$\text{atomic mass} = \left(\begin{array}{l}\text{fraction of atoms}\\ \text{that are } {}^{79}\text{Br} \times\\ \text{mass of } {}^{79}\text{Br}\end{array}\right) + \left(\begin{array}{l}\text{fraction of atoms}\\ \text{that are } {}^{81}\text{Br} \times\\ \text{mass of } {}^{81}\text{Br}\end{array}\right)$$

Because the percent natural abundances must total 100%, the percent natural abundance of ^{81}Br is $100\% - 50.69\% = 49.31\%$. Substituting 79.904 u for the atomic mass, 78.9183 u for the mass of ^{79}Br, and the fractional abundances of the two isotopes, we obtain

$$\begin{aligned}79.904\text{ u} &= (0.5069 \times 78.9183\text{ u}) + (0.4931 \times \text{mass of } {}^{81}\text{Br})\\ &= 40.00\text{ u} + (0.4931 \times \text{mass of } {}^{81}\text{Br})\end{aligned}$$

$$\text{mass of } {}^{81}\text{Br} = \frac{79.904\text{ u} - 40.00\text{ u}}{0.4931} = 80.92\text{ u}$$

To four significant figures, the natural abundance of the bromine-81 isotope is 49.31% and its mass is 80.92 u.

Assess

We can check the final result by working the problem in reverse and using numbers that are slightly rounded. The atomic mass of Br is $50.69\% \times 78.92\text{ u} + 49.31\% \times 80.92\text{ u} \approx \frac{1}{2}(79\text{ u} + 81\text{ u}) = 80\text{ u}$. The estimated atomic mass (80 u) is close to the actual atomic mass of 79.904 u.

PRACTICE EXAMPLE A: The masses and percent natural abundances of the three naturally occurring isotopes of silicon are ^{28}Si, 27.9769265325 u, 92.223%; ^{29}Si, 28.976494700 u, 4.685%; ^{30}Si, 29.973377017 u, 3.092%. Calculate the weighted-average atomic mass of silicon.

PRACTICE EXAMPLE B: Use data from Example 2-5 to determine the percent natural abundances of lithium-6 and lithium-7.

fluorine means establishing the mass of this type of atom as precisely as possible. The atomic mass of krypton is known less precisely because krypton has six naturally occurring isotopes. Because the percent distribution of the isotopes of krypton differs very slightly from one sample to another, the weighted-average atomic mass of krypton cannot be stated with high precision.

2-5 CONCEPT ASSESSMENT

The value listed for chromium in the table of atomic masses inside the front cover is 51.9961 u. Should we conclude that naturally occurring chromium atoms are all of the type $^{52}_{24}$Cr? The same table lists a value of 65.409 u for zinc. Should we conclude that zinc occurs as a mixture of isotopes? Explain.

2-6 Introduction to the Periodic Table

Scientists spend a lot of time organizing information into useful patterns. Before they can organize information, however, they must possess it, and it must be correct. Botanists had enough information about plants to organize their field in the eighteenth century. Because of uncertainties in atomic masses and because many elements remained undiscovered, chemists were not able to organize the elements until a century later.

We can distinguish one element from all others by its particular set of observable physical properties. For example, sodium has a low density of 0.971 g/cm^3 and a low melting point of 97.81 °C. No other element has this same combination of density and melting point. Potassium, though, also has a low density (0.862 g/cm^3) and low melting point (63.65 °C), much like sodium. Sodium and potassium further resemble each other in that both are good conductors of heat and electricity, and both react vigorously with water to liberate hydrogen gas. Gold, conversely, has a density (19.32 g/cm^3) and melting point (1064 °C) that are very much higher than those of sodium or potassium, and gold does not react with water or even with ordinary acids. It does resemble sodium and potassium in its ability to conduct heat and electricity, however. Chlorine is very different still from sodium, potassium, and gold. It is a gas under ordinary conditions, which means that the melting point of solid chlorine (−101 °C) is far below room temperature. Also, chlorine is a nonconductor of heat and electricity.

Even from these very limited data, we get an inkling of a useful classification scheme of the elements. If the scheme is to group together elements with similar properties, then sodium and potassium should appear in the same group. And if the classification scheme is in some way to distinguish between elements that are good conductors of heat and electricity and those that are not, chlorine should be set apart from sodium, potassium, and gold. The classification system we need is the one shown in Figure 2-15 (and inside the front cover), known as the **periodic table** of the elements. In

KEEP IN MIND

that the periodic table shown in Figure 2-15 is the one currently recommended by IUPAC. The discovery of element 112 has recently been authenticated by IUPAC (in May 2009) but the element has not yet been named. Elements with atomic numbers greater than 112 have been reported but not fully authenticated. In Figure 2-15, lutetium (Lu) and lawrencium (Lr) are the last members of the lanthanide and actinide series, respectively. A strong argument* has been made for placing Lu and Lr in group 3, meaning the lanthanide series would end with ytterbium (Yb) and the actinide series would end with nobelium (Nb). To date, IUPAC has not endorsed placing Lu and Lr in group 3.

▲ FIGURE 2-15
Periodic table of the elements
Atomic masses are relative to carbon-12. For certain radioactive elements, the numbers listed in parentheses are the mass numbers of the most stable isotopes. Metals are shown in tan, nonmetals in blue, and metalloids in green. The noble gases (also nonmetals) are shown in pink.

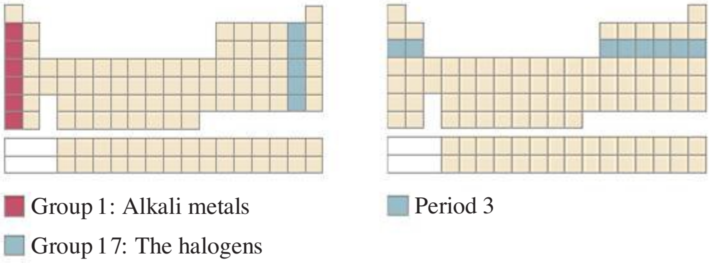
---

* See W. B. Jensen, *J. Chem. Educ.*, **59**, 634 (1982).

Chapter 9, we will describe how the periodic table was formulated, and we will also learn its theoretical basis. For the present, we will consider only a few features of the table.

Features of the Periodic Table In the periodic table, elements are listed according to increasing atomic number starting at the upper left and arranged in a series of horizontal rows. This arrangement places similar elements in *vertical* **groups**, or **families**. For example, sodium and potassium are found together in a group labeled 1 (called the *alkali metals*). We should expect other members of the group, such as cesium and rubidium, to have properties similar to sodium and potassium. Chlorine is found at the other end of the table in a group labeled 17. Some of the groups are given distinctive names, mostly related to an important property of the elements in the group. For example, the group 17 elements are called the *halogens*, a term derived from Greek, meaning "salt former."

▶ That elements in one group have similar properties is perhaps the most useful simplifying feature of atomic properties. Significant differences within a group do occur. The manner and reason for such differences is much of what we try to discover in studying chemistry.



Each element is listed in the periodic table by placing its symbol in the middle of a box in the table. The atomic number (Z) of the element is shown above the symbol, and the weighted-average atomic mass of the element is shown below its symbol. Some periodic tables provide other information, such as density and melting point, but the atomic number and atomic mass are generally sufficient for our needs. Elements with atomic masses in parentheses, such as plutonium, Pu (244), are produced synthetically, and the number shown is the mass number of the most stable isotope.

It is customary also to divide the elements into two broad categories—**metals** and **nonmetals**. In Figure 2-15, colored backgrounds are used to distinguish the metals (tan) from the nonmetals (blue and pink). Except for mercury, a liquid, metals are solids at room temperature. They are generally malleable (capable of being flattened into thin sheets), ductile (capable of being drawn into fine wires), and good conductors of heat and electricity, and have a lustrous or shiny appearance. The properties of nonmetals are generally opposite those of metals; for example, nonmetals are poor conductors of heat and electricity. Several of the nonmetals, such as nitrogen, oxygen, and chlorine, are gases at room temperature. Some, such as silicon and sulfur, are brittle solids. One—bromine—is a liquid.

▶ There is lack of agreement on just which elements to label as metalloids. However, they are generally considered either to lie adjacent to the stair-step line or to be close by.

Two other highlighted categories in Figure 2-15 are a special group of nonmetals known as the **noble gases** (pink), and a small group of elements, often called **metalloids** (green), that have some metallic and some nonmetallic properties.

The *horizontal* rows of the table are called **periods**. (The periods are numbered at the extreme left in the periodic table inside the front cover.) The first period of the table consists of just two elements, hydrogen and helium. This is followed by two periods of eight elements each, lithium through neon and sodium through argon. The fourth and fifth periods contain 18 elements each, ranging from potassium through krypton and from rubidium through xenon. The sixth period is a long one of 32 members. To fit this period in a table that is held to a maximum width of 18 members, 15 members of the period are placed at the bottom of the periodic table. This series of 15 elements start with lanthanum ($Z = 57$), and these elements are called the **lanthanides**. The seventh and final period is incomplete (some members are yet to be discovered), but it is known to be a long one. A 15-member series is also extracted from the seventh period and placed at the bottom of the table. Because the elements in this series start with actinium $(Z = 89)$, they are called the **actinides**.

The labeling of the groups of the periodic table has been a matter of some debate among chemists. The 1-18 numbering system used in Figure 2-15 is the one most recently adopted. Group labels previously used in the United States consisted of a letter and a number, closely following the method adopted by Mendeleev, the developer of the periodic table. As seen in Figure 2-15, the A groups 1 and 2 are separated from the remaining A groups (3 to 8) by B groups 1 through 8. The International Union of Pure and Applied Chemistry (IUPAC) recommended the simple 1 to 18 numbering scheme in order to avoid confusion between the American number and letter system and that used in Europe, where some of the A and B designations were switched! Currently, the IUPAC system is officially recommended by the American Chemical Society (ACS) and chemical societies in other nations. Because both numbering systems are in use, we show both in Figure 2-15 and in the periodic table inside the front cover. However, except for an occasional reminder of the earlier system, we will use the IUPAC numbering system in this text.

◀ Mendeleev's arrangement of the elements in the original periodic table was based on observed chemical and physical properties of the elements and their compounds. The arrangement of the elements in the modern periodic table is based on atomic properties–atomic number and electron configuration.

Useful Relationships from the Periodic Table

The periodic table helps chemists describe and predict the properties of chemical compounds and the outcomes of chemical reactions. Throughout this text, we will use it as an aid to understanding chemical concepts. One application of the table worth mentioning here is how it can be used to predict likely charges on simple monatomic ions.

Main-group elements are those in groups 1, 2, and 13 to 18. When main-group metal atoms in groups 1 and 2 form ions, they lose the same number of electrons as the IUPAC group number. Thus, Na atoms (group 1) lose one electron to become Na^+, and Ca atoms (group 2) lose two electrons to

EXAMPLE 2-7 Describing Relationships Based on the Periodic Table

Refer to the periodic table on the inside front cover, and indicate

(a) the element that is in group 14 and the fourth period;
(b) two elements with properties similar to those of molybdenum (Mo);
(c) the ion most likely formed from a strontium atom.

Analyze

For **(a)**, the key concept is that the rows (periods) are numbered 1 through 7, starting from the top of the periodic table, and the groups are numbered 1 through 18, starting from the left side. For **(b)**, the key concept is that elements in the same group have similar properties. For **(c)**, the key concept is that main-group metal atoms in groups 1 and 2 form positive ions with charges of +1 and +2, respectively.

Solve

(a) The elements in the fourth period range from K $(Z = 19)$ to Kr $(Z = 36)$. Those in group 14 are C, Si, Ge, Sn, and Pb. The only element that is common to both of these groupings is Ge $(Z = 32)$.

(b) Molybdenum is in group 6. Two other members of this group that should resemble it are chromium (Cr) and tungsten (W).

(c) Strontium (Sr) is in group 2. It should form the ion Sr^{2+}.

Assess

In Chapter 8, we will examine in greater detail reasons for the arrangement of the periodic table.

PRACTICE EXAMPLE A: Write a symbol for the ion most likely formed by an atom of each of the following: Li, S, Ra, F, I, and Al.

PRACTICE EXAMPLE B: Classify each of the following elements as a main-group or transition element. Also, specify whether they are metals, metalloids, or nonmetals: Na, Re, S, I, Kr, Mg, U, Si, B, Al, As, H.

become Ca^{2+}. Aluminum, in group 13, loses three electrons to form Al^{3+} (here the charge is "group number minus 10"). The few other metals in groups 13 and higher form more than one possible ion, a matter that we deal with in Chapter 9.

When nonmetal atoms form ions, they gain electrons. The number of electrons gained is normally 18 minus the IUPAC group number. Thus, an O atom gains $18 - 16 = 2$ electrons to become O^{2-}, and a Cl atom gains $18 - 17 = 1$ electron to become Cl^{-}. The "18 minus group number" rule suggests that an atom of Ne in group 18 gains no electrons: $18 - 18 = 0$. The very limited tendency of the noble gas atoms to form ions is one of several characteristics of this family of elements.

The elements in groups 3 to 12 are the **transition elements**, and because all of them are metals, they are also called the **transition metals**. Like the main-group metals, the transition metals form positive ions, but the number of electrons lost is not related in any simple way to the group number, mostly because transition metals can form two or more ions of differing charge.

2-7 The Concept of the Mole and the Avogadro Constant

Starting with Dalton, chemists have recognized the importance of relative numbers of atoms, as in the statement that *two* hydrogen atoms and *one* oxygen atom combine to form *one* molecule of water. Yet it is physically impossible to count every atom in a macroscopic sample of matter. Instead, some other measurement must be employed, which requires a relationship between the measured quantity, usually mass, and some known, but uncountable, number of atoms. Consider a practical example of mass substituting for a desired number of items. Suppose you want to nail down new floorboards on the deck of a mountain cabin, and you have calculated how many nails you will need. If you have an idea of how many nails there are in a pound, then you can buy the nails by the pound.

The SI quantity that describes an amount of substance by relating it to a number of particles of that substance is called the *mole* (abbreviated *mol*). A **mole** is the amount of a substance that contains the same number of elementary entities as there are atoms in exactly 12 g of pure carbon-12. The "number of elementary entities (atoms, molecules, and so on)" in a mole is the **Avogadro constant, N_A.**

▶ Because the value of Avogadro's number depends, in part, on a measurement, the value has changed slightly over the years. The values recommended since 1986 by the Committee on Data for Science and Technology (CODATA) are listed below.

Year	Avogadro's Number
1986	6.0221367×10^{23}
1998	$6.02214199 \times 10^{23}$
2002	6.0221415×10^{23}
2006	$6.02214179 \times 10^{23}$

$$N_A = 6.02214179 \times 10^{23}\ \text{mol}^{-1} \qquad \textbf{(2.4)}$$

The Avogadro constant consists of a number, $6.02214179 \times 10^{23}$, known as Avogadro's *number*, and a unit, mol^{-1}. The unit mol^{-1} signifies that the entities being counted are those present in 1 mole.

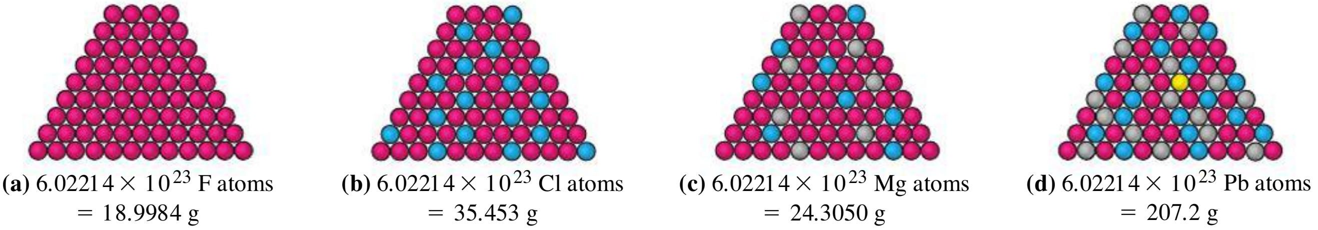
The value of Avogadro's number is based on both a definition and a measurement. A mole of carbon-12 is *defined* to be 12 g. If the mass of one carbon-12 atom is *measured* by using a mass spectrometer (see Figure 2-14), the mass would be about 1.9926×10^{-23} g. The ratio of these two masses provides an estimate of Avogadro's number. In actual fact, accurate determinations of Avogadro's number make use of other measurements, not the measurement of the mass of a single atom of carbon-12.

▶ When rounding Avogadro's number or any other accurately known value, keep one more significant figure than that of the least accurate number in the calculation to avoid rounding errors.

Often the value of N_A is rounded off to $6.022 \times 10^{23}\ \text{mol}^{-1}$, or even to $6.02 \times 10^{23}\ \text{mol}^{-1}$.

If a substance contains atoms of only a single isotope, then

$$1\ \text{mol}\ {}^{12}\text{C} = 6.02214 \times 10^{23}\ {}^{12}\text{C atoms} = 12.0000\ \text{g}$$
$$1\ \text{mol}\ {}^{16}\text{O} = 6.02214 \times 10^{23}\ {}^{16}\text{O atoms} = 15.9949\ \text{g (and so on)}$$



(a) 6.02214×10^{23} F atoms $= 18.9984$ g

(b) 6.02214×10^{23} Cl atoms $= 35.453$ g

(c) 6.02214×10^{23} Mg atoms $= 24.3050$ g

(d) 6.02214×10^{23} Pb atoms $= 207.2$ g

▲ FIGURE 2-16
Distribution of isotopes in four elements
(a) There is only one type of fluorine atom, ^{19}F (shown in red). (b) In chlorine, 75.77% of the atoms are ^{35}Cl (red) and the remainder are ^{37}Cl (blue). (c) Magnesium has one principal isotope, ^{24}Mg (red), and two minor ones, ^{25}Mg (gray) and ^{26}Mg (blue). (d) Lead has four naturally occurring isotopes: 1.4% ^{204}Pb (yellow), 24.1% ^{206}Pb (blue), 22.1% ^{207}Pb (gray), and 52.4% ^{208}Pb (red).

Most elements are composed of mixtures of two or more isotopes so that the atoms in a sample of the element are not all of the same mass but are present in their naturally occurring proportions. Thus, in one mole of carbon, most of the atoms are carbon-12, but some are carbon-13. In one mole of oxygen, most of the atoms are oxygen-16, but some are oxygen-17 and some are oxygen-18. As a result,

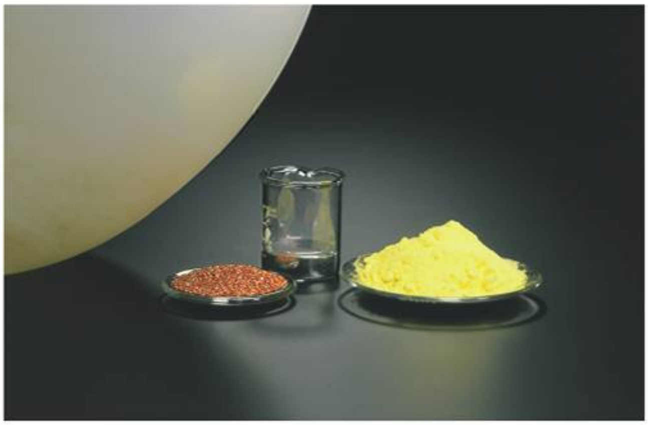
$$1 \text{ mol of C} = 6.02214 \times 10^{23} \text{ C atoms} = 12.0107 \text{ g}$$
$$1 \text{ mol of O} = 6.02214 \times 10^{23} \text{ O atoms} = 15.9994 \text{ g, and so on.}$$

The Avogadro constant was purposely chosen so that the mass of one mole of carbon-12 atoms—exactly 12 g—would have the same *numeric* value as the mass of a single carbon-12 atom—exactly 12 u. As a result, for all other elements the numeric value of the mass in grams of one mole of atoms and the weighted-average atomic mass in atomic mass units are equal. For example, the weighted average atomic mass of lithium is 6.941 u and the mass of one mole of lithium atoms is 6.941 g. Thus, we can easily establish the mass of one mole of atoms, called the **molar mass, *M***, from a table of atomic masses.* For example, the molar mass of lithium is 6.941 g Li/mol Li. Figure 2-16 attempts to portray the distribution of isotopes of an element, and Figure 2-17 pictures one mole each of four common elements.

◀ The weighted-average atomic mass of carbon was calculated on page 48.

KEEP IN MIND

that molar mass has the unit g/mol.



◀ FIGURE 2-17
One mole of an element
The watch glasses contain one mole of copper atoms (left) and one mole of sulfur atoms (right). The beaker contains one mole of mercury atoms as liquid mercury, and the balloon, of which only a small portion is visible here, contains one mole of helium atoms in the gaseous state.

---

*Atomic mass (atomic weight) values in tables are often written without units, especially if they are referred to as *relative* atomic masses. This simply means that the values listed are in relation to *exactly* 12 (rather than 12 u) for carbon-12. We will use the atomic mass unit (u) when referring to atomic masses (atomic weights). Most chemists do.

2-6 CONCEPT ASSESSMENT

Dividing the molar mass of gold by the Avogadro constant yields the mass of any individual atom of naturally occurring gold. In contrast, no naturally occurring atom of silver has the mass obtained by dividing the molar mass of silver by the Avogadro constant. How can this be?

Thinking About Avogadro's Number

Avogadro's number (6.02214×10^{23}) is an enormously large number and practically inconceivable in terms of ordinary experience. Suppose we were counting garden peas instead of atoms. If the typical pea had a volume of about 0.1 cm^3, the required pile of peas would cover the United States to a depth of about 6 km (4 mi). Or imagine that grains of wheat could be counted at the rate of 100 per minute. A given individual might be able to count out about 4 billion grains in a lifetime. Even so, if all the people currently on Earth were to spend their lives counting grains of wheat, they could not reach Avogadro's number. In fact, if all the people who ever lived on Earth had spent their lifetimes counting grains of wheat, the total would still be far less than Avogadro's number. (And Avogadro's number of wheat grains is far more wheat than has been produced in human history.) Now consider a much more efficient counting device, a modern personal computer; it is capable of counting at a rate of about 1 billion units per second. The task of counting out Avogadro's number would still take about 20 million years!

▶ You will have an opportunity to calculate a value of N_A at several points in the text, starting with Exercise 113 in Chapter 3.

Avogadro's number is clearly not a useful number for counting ordinary objects. However, when this inconceivably large number is used to count inconceivably small objects, such as atoms and molecules, the result is a quantity of material that is easily within our grasp, essentially a "handful."

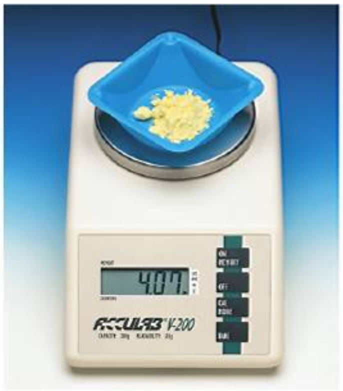
2-8 Using the Mole Concept in Calculations

Throughout the text, the mole concept will provide conversion factors for problem-solving situations. With each new situation, we will explore how the mole concept applies. For now, we will deal with the relationship between numbers of atoms and the mole. Consider the statement: 1 mol S = 6.022×10^{23} S atoms = 32.065 g S. This allows us to write the conversion factors

$$\frac{1 \text{ mol S}}{6.022 \times 10^{23} \text{ S atoms}} \quad \text{and} \quad \frac{32.065 \text{ g S}}{1 \text{ mol S}}$$

In calculations requiring the Avogadro constant, students often ask when to multiply and when to divide by N_A. One answer is always to use the constant in a way that gives the proper cancellation of units. Another answer is to think in terms of the expected result. In calculating a number of atoms, we expect the answer to be a very large number and certainly *never* smaller than one. The number of moles of atoms, conversely, is generally a number of more modest size and will often be less than one.

In the following examples, we use atomic masses and the Avogadro constant in calculations to determine the number of atoms present in a given sample. Atomic masses and the Avogadro constant are known rather precisely, and students often wonder how many significant figures to carry in atomic masses or the Avogadro constant when performing calculations. Here is a useful rule of thumb.



▲ FIGURE 2-18 **Measurement of 7.64×10^{22} S atoms (0.127 mol S)—Example 2-8 illustrated**
The balance was set to zero (tared) when just the weighing boat was present. The sample of sulfur weighs 4.07 g.

To ensure the maximum precision allowable, carry at least one more significant figure in well-known physical constants than in other measured quantities.

For example, in calculating the mass of 0.600 mol of sulfur, we should use the atomic mass of S with *at least* four significant figures. The answer 0.600 mol S × 32.07 g S/mol S = 19.2 g S is a more precise response than 0.600 mol S × 32.1 g S/mol S = 19.3 g S.

EXAMPLE 2-8 Relating Number of Atoms, Amount in Moles, and Mass in Grams

In the sample of sulfur weighing 4.07 g pictured in Figure 2-18, **(a)** how many moles of sulfur are present, and **(b)** what is the total number of sulfur atoms in the sample?

Analyze

For **(a)**, the conversion pathway is g S → mol S. To carry out this conversion, we multiply 4.07 g S by the conversion factor (1 mol S/32.07 g S). The conversion factor is the molar mass inverted. For **(b)**, the conversion pathway is mol S → atoms S. To carry out this conversion, we multiply the quantity in moles from part **(a)** by the conversion factor (6.022×10^{23} atoms S/1 mol S).

Solve

(a) For the conversion g S → mol S, using ($1/M$) as a conversion factor achieves the proper cancellation of units. The result of this calculation should be stored without rounding it off because it is required in part (b).

$$?\ \text{mol S} = 4.07\ \cancel{\text{g S}} \times \frac{1\ \text{mol S}}{32.07\ \cancel{\text{g S}}} = 0.127\ \text{mol S}$$

(b) The conversion mol S → atoms S is carried out using the Avogadro constant as a conversion factor.

$$?\ \text{atoms S} = 0.127\ \cancel{\text{mol S}} \times \frac{6.022 \times 10^{23}\ \text{atoms S}}{1\ \cancel{\text{mol S}}} = 7.64 \times 10^{22}\ \text{atoms S}$$

Assess

By including units in our calculations, we can check that proper cancellation of units occurs. Also, if our only concern is to calculate the number of sulfur atoms in the sample, the calculations carried out in parts **(a)** and **(b)** could be combined into a single calculation, as shown below.

$$?\ \text{atoms S} = 4.07\ \cancel{\text{g S}} \times \frac{1\ \cancel{\text{mol S}}}{32.07\ \cancel{\text{g S}}} \times \frac{6.022 \times 10^{23}\ \text{atoms S}}{1\ \cancel{\text{mol S}}} = 7.64 \times 10^{22}\ \text{atoms S}$$

Had we rounded 4.07 g S × (1 mol S/32.07 g S) to 0.127 mol S and used the rounded result in part (b), we would have obtained a final answer of 7.65×10^{22} atoms S. With a single line calculation, we do not have to write down an intermediate result and we avoid round-off errors.

PRACTICE EXAMPLE A: What is the mass of 2.35×10^{24} atoms of Cu?

PRACTICE EXAMPLE B: How many lead-206 atoms are present in a 22.6 g sample of lead metal? [*Hint:* See Figure 2-16.]

Example 2-9 is perhaps the most representative use of the mole concept. Here it is part of a larger problem that requires other unrelated conversion factors as well. One approach is to outline a conversion pathway to get from the given to the desired information.

EXAMPLE 2-9 Combining Several Factors in a Calculation—Molar Mass, the Avogadro Constant, Percent Abundances

Potassium-40 is one of the few naturally occurring radioactive isotopes of elements of low atomic number. Its percent natural abundance among K isotopes is 0.012%. How many ^{40}K atoms are present in 225 mL of whole milk containing 1.65 mg K/mL?

(continued)

Analyze

Ultimately we need to complete the conversion mL milk → atoms ^{40}K. There is no single conversion factor that allows us to complete this conversion in one step, so we anticipate having to complete several steps or conversions. We are told the milk contains 1.65 mg K/mL = 1.65×10^{-3} g K/mL, and this information can be used to carry out the conversion mL milk → g K. We can carry out the conversions g K → mol K → atoms K by using conversion factors based on the molar mass of K and the Avogadro constant. The final conversion, atoms K → atoms ^{40}K, can be carried out by using a conversion factor based on the percent natural abundance of ^{40}K. A complete conversion pathway is shown below:

$$\text{mL milk} \rightarrow \text{mg K} \rightarrow \text{g K} \rightarrow \text{mol K} \rightarrow \text{atoms K} \rightarrow \text{atoms } ^{40}\text{K}$$

Solve

The required conversions can be carried out in a stepwise fashion, or they can be combined into a single line calculation. Let's use a stepwise approach. First, we convert from mL milk to g K.

$$? \text{ g K} = 225 \text{ mL milk} \times \frac{1.65 \text{ mg K}}{1 \text{ mL milk}} \times \frac{1 \text{ g K}}{1000 \text{ mg K}} = 0.371 \text{ g K}$$

Next, we convert from g K to mol K,

$$? \text{ mol K} = 0.371 \text{ g K} \times \frac{1 \text{ mol K}}{39.10 \text{ g K}} = 9.49 \times 10^{-3} \text{ mol K}$$

and then we convert from mol K to atoms K.

$$? \text{ atoms K} = 9.49 \times 10^{-3} \text{ mol K} \times \frac{6.022 \times 10^{23} \text{ atoms K}}{1 \text{ mol K}} = 5.71 \times 10^{21} \text{ atoms K}$$

Finally, we convert from atoms K to atoms ^{40}K.

$$? \text{ atoms } ^{40}\text{K} = 5.71 \times 10^{21} \text{ atoms K} \times \frac{0.012 \text{ atoms } ^{40}\text{K}}{100 \text{ atoms K}} = 6.9 \times 10^{17} \text{ atoms } ^{40}\text{K}$$

Assess

The final answer is rounded to two significant figures because the least precisely known quantity in the calculation, the percent natural abundance of ^{40}K, has two significant figures. It is possible to combine the steps above into a single line calculation.

$$? \text{ atoms } ^{40}\text{K} = 225 \text{ mL milk} \times \frac{1.65 \text{ mg K}}{1 \text{ mL milk}} \times \frac{1 \text{ g K}}{1000 \text{ mg K}} \times \frac{1 \text{ mol K}}{39.10 \text{ g K}}$$

$$\times \frac{6.022 \times 10^{23} \text{ atoms K}}{1 \text{ mol K}} \times \frac{0.012 \text{ atoms } ^{40}\text{K}}{100 \text{ atoms K}}$$

$$= 6.9 \times 10^{17} \text{ atoms } ^{40}\text{K}$$

PRACTICE EXAMPLE A: How many Pb atoms are present in a small piece of lead with a volume of 0.105 cm^3? The density of Pb = 11.34 g/cm^3.

PRACTICE EXAMPLE B: Rhenium-187 is a radioactive isotope that can be used to determine the age of meteorites. A 0.100 mg sample of Re contains 2.02×10^{17} atoms of ^{187}Re. What is the percent abundance of rhenium-187 in the sample?

MasteringCHEMISTRY **www.masteringchemistry.com**

What is the most abundant element? This seemingly simple question does not have a simple answer. To learn more about the abundances of elements in the universe and in the Earth's crust, go to the Focus On feature for Chapter 2, entitled Occurrence and Abundances of the Elements, on the MasteringChemistry site.

Summary

2-1 Early Chemical Discoveries and the Atomic Theory—Modern chemistry began with eighteenth-century discoveries leading to the formulation of two basic laws of chemical combination, the **law of conservation of mass** and the **law of constant composition (definite proportions)**. These discoveries led to Dalton's atomic theory—that matter is composed of indestructible particles called atoms, that the atoms of an element are identical to one another but different from atoms of all other elements, and that chemical compounds are combinations of atoms of different elements. Based on this theory, Dalton proposed still another law of chemical combination, the **law of multiple proportions**.

2-2 Electrons and Other Discoveries in Atomic Physics—The first clues to the structures of atoms came through the discovery and characterization of **cathode rays** (**electrons**). Key experiments were those that established the mass-to-charge ratio (Fig. 2-7) and then the charge on an electron (Fig. 2-8). Two important accidental discoveries made in the course of cathode-ray research were of X-rays and **radioactivity**. The principal types of radiation emitted by radioactive substances are **alpha** (α) **particles**, **beta** (β) **particles**, and **gamma** (γ) **rays** (Fig. 2-10).

2-3 The Nuclear Atom—Studies on the scattering of α particles by thin metal foils (Fig. 2-11) led to the concept of the nuclear atom—a tiny, but massive, positively charged nucleus surrounded by lightweight, negatively charged electrons (Fig. 2-12). A more complete description of the nucleus was made possible by the discovery of **protons** and **neutrons**. An individual atom is characterized in terms of its **atomic number** (**proton number**) Z and **mass number**, A. The difference, $A - Z$, is the **neutron number**. The masses of individual atoms and their component parts are expressed in **atomic mass units** (**u**).

2-4 Chemical Elements—All elements from $Z = 1$ to $Z = 112$ have been characterized and all but element 112 have been given a name and **chemical symbol**. Knowledge of the several elements following $Z = 112$ is more tenuous. **Nuclide** is the term used to describe an atom with a particular atomic number and a particular mass number. Atoms of the same element that differ in mass number are called **isotopes**. The **percent natural abundance** of an isotope and the precise mass of its atoms can be established with a **mass spectrometer** (Fig. 2-14). A special symbolism (expression 2.2) is used to represent the composition of an atom or an **ion** derived from the atom.

2-5 Atomic Mass—The **atomic mass** (**weight**) of an element is a weighted average based on an assigned value of exactly 12 u for the isotope carbon-12. This weighted average is calculated from the experimentally determined atomic masses and percent abundances of the naturally occurring isotopes of the element through expression (2.3).

2-6 Introduction to the Periodic Table—The **periodic table** (Fig. 2-15) is an arrangement of the elements in horizontal rows called **periods** and vertical columns called **groups** or **families**. Each group consists of elements with similar physical and chemical properties. The elements can also be subdivided into broad categories. One categorization is that of **metals**, **nonmetals**, **metalloids**, and **noble gases**. Another is that of **main-group elements** and **transition elements** (**transition metals**). Included among the transition elements are the two subcategories **lanthanides** and **actinides**. The table has many uses, as will be seen throughout the text. Emphasis in this chapter is on the periodic table as an aid in writing symbols for simple ions.

2-7 The Concept of the Mole and Avogadro Constant—The **Avogadro constant**, $N_A = 6.02214 \times 10^{23}\ \text{mol}^{-1}$, represents the number of carbon-12 atoms in *exactly* 12 g of carbon-12. More generally, it is the number of elementary entities (for example, atoms or molecules) present in an amount known as one **mole** of substance. The mass of one mole of atoms of an element is called its **molar mass**, M.

2-8 Using the Mole Concept in Calculations—Molar mass and the Avogadro constant are used in a variety of calculations involving the mass, amount (in moles), and number of atoms in a sample of an element. Other conversion factors may also be involved in these calculations. The mole concept is encountered in ever broader contexts throughout the text.

Integrative Example

A stainless steel ball bearing has a radius of 6.35 mm and a density of 7.75 g/cm^3. Iron is the principal element in steel. Carbon is a key minor element. The ball bearing contains 0.25% carbon, by mass. Given that the percent natural abundance of ^{13}C is 1.108%, how many ^{13}C atoms are present in the ball bearing?

Analyze

The goal is to determine the number of carbon-13 atoms found in a ball bearing with a particular composition. The critical point in this problem is recognizing that we can relate number of atoms to mass by using molar mass and Avogadro's constant. The first step is to use the radius of the ball bearing to determine its volume. The second step is to determine the mass of carbon present by using the density of steel along with the percent composition. The third step uses the molar mass of carbon to convert grams of carbon to moles of carbon; Avogadro's constant is then used to convert moles of carbon to the number of carbon atoms. In the final step, the natural abundance of carbon-13 atoms is used to find the number of carbon-13 atoms in the total number of carbon atoms in the ball bearing.

Solve

The ball-bearing volume in cubic centimeters is found by applying the formula for the volume of a sphere, $V = 4/3\,\pi r^3$. Remember to convert the given radius from millimeters to centimeters, so that the volume will be in cubic centimeters.

$$V = \frac{4\pi}{3}\left[6.35\text{ mm} \times \frac{1\text{ cm}}{10\text{ mm}}\right]^3 = 1.07\text{ cm}^3$$

The product of the volume of the ball bearing and the density of steel equals the mass. The mass of the ball bearing multiplied by the percent carbon in the steel gives the mass of carbon present.

$$?\text{ g C} = 1.07\text{ cm}^3 \times \frac{7.75\text{ g steel}}{1\text{ cm}^3\text{ steel}} \times \frac{0.25\text{ g C}}{100\text{ g steel}} = 0.021\text{ g C}$$

The mass of carbon is first converted to moles of carbon by using the inverse of the molar mass of carbon. Avogadro's constant is then used to convert moles of carbon to atoms of carbon.

$$?\text{ C atoms} = 0.021\text{ g C} \times \frac{1\text{ mol C}}{12.011\text{ g C}} \times \frac{6.022 \times 10^{23}\text{ C atoms}}{1\text{ mol C}}$$
$$= 1.1 \times 10^{21}\text{ C atoms}$$

The number of ^{13}C atoms is determined by using the percent natural abundance of carbon-13.

$$?\ ^{13}\text{C atoms} = 1.1 \times 10^{21}\text{ C atoms} \times \frac{1.108\ ^{13}\text{C atoms}}{100\text{ C atoms}}$$
$$= 1.2 \times 10^{19}\ ^{13}\text{C atoms}$$

Assess

The number of carbon-13 atoms is smaller than the number of carbon atoms, which it should be, given that the natural abundance of carbon-13 is just 1.108%. To avoid mistakes, every quantity should be clearly labeled with its appropriate unit so that units cancel properly. Two points made by this problem are, first, that the relatively small ball bearing contains a large number of carbon-13 atoms even though carbon-13's abundance is only 1.108% of all carbon atoms. Second, the size of any atom must be very small.

PRACTICE EXAMPLE A: Calculate the number of ^{63}Cu atoms in a cubic crystal of copper that measures 25 nm on edge. The density of copper is 8.92 g/cm^3 and the percent natural abundance of ^{63}Cu is 69.17%.

PRACTICE EXAMPLE B: The United States Food and Drug Administration (USFDA) suggests a daily value of 18 mg Fe for adults and for children over four years of age. The label on a particular brand of cereal states that one serving (55 g) of dry cereal contains 45% of the daily value of Fe. Given that the percent natural abundance of ^{58}Fe is 0.282%, how many full servings of dry cereal must be eaten to consume exactly one mole of ^{58}Fe? The atomic weight of ^{58}Fe is 57.9333 u. Is it possible for a person to consume this much cereal in a lifetime, assuming that one full serving of cereal is eaten every day?

Exercises

Law of Conservation of Mass

1. When an iron object rusts, its mass increases. When a match burns, its mass decreases. Do these observations violate the law of conservation of mass? Explain.
2. When a strip of magnesium metal is burned in air (recall Figure 2-1), it produces a white powder that weighs more than the original metal. When a strip of magnesium is burned in a flashbulb, the bulb weighs the same before and after it is flashed. Explain the difference in these observations.
3. A 0.406 g sample of magnesium reacts with oxygen, producing 0.674 g of magnesium oxide as the only product. What mass of oxygen was consumed in the reaction?
4. A 1.446 g sample of potassium reacts with 8.178 g of chlorine to produce potassium chloride as the only product. After the reaction, 6.867 g of chlorine remains unreacted. What mass of potassium chloride was formed?
5. When a solid mixture consisting of 10.500 g calcium hydroxide and 11.125 g ammonium chloride is strongly heated, gaseous products are evolved and 14.336 g of a solid residue remains. The gases are passed into 62.316 g water, and the mass of the resulting solution is 69.605 g. Within the limits of experimental error, show that these data conform to the law of conservation of mass.
6. Within the limits of experimental error, show that the law of conservation of mass was obeyed in the following experiment: 10.00 g calcium carbonate (found in limestone) was dissolved in 100.0 mL hydrochloric acid ($d = 1.148$ g/mL). The products were 120.40 g solution (a mixture of hydrochloric acid and calcium chloride) and 2.22 L carbon dioxide gas ($d = 1.9769$ g/L).

Law of Constant Composition

7. In Example 2-1, we established that the mass ratio of magnesium to magnesium oxide is 0.455 g magnesium/0.755 g magnesium oxide.
(a) What is the ratio of oxygen to magnesium oxide, by mass?
(b) What is the mass ratio of oxygen to magnesium in magnesium oxide?
(c) What is the percent by mass of magnesium in magnesium oxide?

8. Samples of pure carbon weighing 3.62, 5.91, and 7.07 g were burned in an excess of air. The masses of carbon dioxide obtained (the sole product in each case) were 13.26, 21.66, and 25.91 g, respectively.
(a) Do these data establish that carbon dioxide has a fixed composition?
(b) What is the composition of carbon dioxide, expressed in % C and % O, by mass?

9. In one experiment, 2.18 g sodium was allowed to react with 16.12 g chlorine. All the sodium was used up, and 5.54 g sodium chloride (salt) was produced. In a second experiment, 2.10 g chlorine was allowed to react with 10.00 g sodium. All the chlorine was used up, and 3.46 g sodium chloride was produced. Show that these results are consistent with the law of constant composition.

10. When 3.06 g hydrogen was allowed to react with an excess of oxygen, 27.35 g water was obtained. In a second experiment, a sample of water was decomposed by electrolysis, resulting in 1.45 g hydrogen and 11.51 g oxygen. Are these results consistent with the law of constant composition? Demonstrate why or why not.

11. In one experiment, the burning of 0.312 g sulfur produced 0.623 g sulfur dioxide as the sole product of the reaction. In a second experiment, 0.842 g sulfur dioxide was obtained. What mass of sulfur must have been burned in the second experiment?

12. In one experiment, the reaction of 1.00 g mercury and an excess of sulfur yielded 1.16 g of a sulfide of mercury as the sole product. In a second experiment, the same sulfide was produced in the reaction of 1.50 g mercury and 1.00 g sulfur.
(a) What mass of the sulfide of mercury was produced in the second experiment?
(b) What mass of which element (mercury or sulfur) remained *unreacted* in the second experiment?

Law of Multiple Proportions

13. Sulfur forms two compounds with oxygen. In the first compound, 1.000 g sulfur is combined with 0.998 g oxygen, and in the second, 1.000 g sulfur is combined with 1.497 g oxygen. Show that these results are consistent with Dalton's law of multiple proportions.

14. Phosphorus forms two compounds with chlorine. In the first compound, 1.000 g of phosphorus is combined with 3.433 g chlorine, and in the second, 2.500 g phosphorus is combined with 14.308 g chlorine. Show that these results are consistent with Dalton's law of multiple proportions.

15. The following data were obtained for compounds of nitrogen and hydrogen:

Compound	Mass of Nitrogen, g	Mass of Hydrogen, g
A	0.500	0.108
B	1.000	0.0720
C	0.750	0.108

(a) Show that these data are consistent with the law of multiple proportions.
(b) If the formula of compound B is N_2H_2, what are the formulas of compounds A and C?

16. The following data were obtained for compounds of iodine and fluorine:

Compound	Mass of Iodine, g	Mass of Fluorine, g
A	1.000	0.1497
B	0.500	0.2246
C	0.750	0.5614
D	1.000	1.0480

(a) Show that these data are consistent with the law of multiple proportions.
(b) If the formula for compound A is IF, what are the formulas for compounds B, C, and D?

17. There are two oxides of copper. One oxide has 20% oxygen, by mass. The second oxide has a *smaller* percent of oxygen than the first. What is the probable percent of oxygen in the second oxide?

18. The two oxides of carbon described on page 38 were CO and CO_2. Another oxide of carbon has 1.106 g of oxygen in a 2.350 g sample. In what ratio are carbon and oxygen atoms combined in molecules of this third oxide? Explain.

Fundamental Charges and Mass-to-Charge Ratios

19. The following observations were made for a series of five oil drops in an experiment similar to Millikan's (see Figure 2-8). Drop 1 carried a charge of 1.28×10^{-18} C; drops 2 and 3 each carried $\frac{1}{2}$ the charge of drop 1; drop 4 carried $\frac{1}{8}$ the charge of drop 1; drop 5 had a charge four times that of drop 1. Are these data consistent with the value of the electronic charge given in the text? Could Millikan have inferred the charge on the electron from this particular series of data? Explain.

20. In an experiment similar to that described in Exercise 19, drop 1 carried a charge of 6.41×10^{-19} C; drop 2 had $\frac{1}{2}$ the charge of drop 1; drop 3 had twice the charge of drop 1; drop 4 had a charge of 1.44×10^{-18} C; and drop 5 had $\frac{1}{3}$ the charge of drop 4. Are these data consistent with the value of the electronic charge given in the text? Could Millikan have inferred the charge on the electron from this particular series of data? Explain.

21. Use data from Table 2.1 to verify that
(a) the mass of electrons is about 1/2000 that of H atoms;
(b) the mass-to-charge ratio (m/e) for positive ions is considerably larger than that for electrons.

22. Determine the approximate value of m/e in coulombs per gram for the ions ${}^{127}_{53}\mathrm{I}^-$ and ${}^{32}_{16}\mathrm{S}^{2-}$. Why are these values only approximate?

Atomic Number, Mass Number, and Isotopes

23. The following radioactive isotopes have applications in medicine. Write their symbols in the form ${}^{A}_{Z}\mathrm{E}$. **(a)** cobalt-60; **(b)** phosphorus-32; **(c)** iron-59; **(d)** radium-226.

24. For the isotope ${}^{202}\mathrm{Hg}$, express the percentage of the fundamental particles in the nucleus that are neutrons.

25. Complete the following table. What minimum amount of information is required to completely characterize an atom or ion?
[*Hint:* Not all rows can be completed.]

Name	Symbol	Number Protons	Number Electrons	Number Neutrons	Mass Number
Sodium	${}^{23}_{11}\mathrm{Na}$	11	11	12	23
Silicon	—	—	—	14	—
—	—	37	—	—	85
—	${}^{40}\mathrm{K}$	—	—	—	—
—	—	—	33	42	—
—	${}^{20}\mathrm{Ne}^{2+}$	—	—	—	—
—	—	—	—	—	80
—	—	—	—	126	—

26. Arrange the following species in order of increasing **(a)** number of electrons; **(b)** number of neutrons; **(c)** mass.

$${}^{112}_{50}\mathrm{Sn} \quad {}^{40}_{18}\mathrm{Ar} \quad {}^{122}_{52}\mathrm{Te} \quad {}^{59}_{29}\mathrm{Cu} \quad {}^{120}_{48}\mathrm{Cd} \quad {}^{58}_{27}\mathrm{Co} \quad {}^{39}_{19}\mathrm{K}$$

27. For the atom ${}^{108}\mathrm{Pd}$ with mass 107.90389 u, determine
(a) the numbers of protons, neutrons, and electrons in the atom;
(b) the ratio of the mass of this atom to that of an atom of ${}^{12}_{6}\mathrm{C}$.

28. For the ion ${}^{228}\mathrm{Ra}^{2+}$ with a mass of 228.030 u, determine
(a) the numbers of protons, neutrons, and electrons in the ion;
(b) the ratio of the mass of this ion to that of an atom of ${}^{16}\mathrm{O}$ (refer to page 47).

29. An isotope of silver has a mass that is 6.68374 times that of oxygen-16. What is the mass in u of this isotope? (Refer to page 47.)

30. The ratio of the masses of the two naturally occurring isotopes of indium is 1.0177:1. The heavier of the two isotopes has 7.1838 times the mass of ${}^{16}\mathrm{O}$. What are the masses in u of the two isotopes? (Refer to page 47.)

31. The following data on isotopic masses are from a chemical handbook. What is the ratio of each of these masses to that of ${}^{12}_{6}\mathrm{C}$? **(a)** ${}^{35}_{17}\mathrm{Cl}$, 34.96885 u; **(b)** ${}^{26}_{12}\mathrm{Mg}$, 25.98259 u; **(c)** ${}^{222}_{86}\mathrm{Rn}$, 222.0175 u.

32. The following ratios of masses were obtained with a mass spectrometer: ${}^{19}_{9}\mathrm{F}/{}^{12}_{6}\mathrm{C} = 1.5832$; ${}^{35}_{17}\mathrm{Cl}/{}^{19}_{9}\mathrm{F} = 1.8406$; ${}^{81}_{35}\mathrm{Br}/{}^{35}_{17}\mathrm{Cl} = 2.3140$. Determine the mass of a ${}^{81}_{35}\mathrm{Br}$ atom in amu.

33. Which of the following species has
(a) equal numbers of neutrons and electrons;
(b) protons, neutrons, and electrons in the ratio 9:11:8;
(c) a number of neutrons equal to the number of protons plus one-half the number of electrons?

$${}^{24}\mathrm{Mg}^{2+},\ {}^{47}\mathrm{Cr},\ {}^{60}\mathrm{Co}^{3+},\ {}^{35}\mathrm{Cl}^{-},\ {}^{124}\mathrm{Sn}^{2+},\ {}^{226}\mathrm{Th},\ {}^{90}\mathrm{Sr}$$

34. Given the same species as listed in Exercise 33, which has
(a) equal numbers of neutrons and protons;
(b) protons contributing more than 50% of the mass;
(c) about 50% more neutrons than protons?

35. An isotope with mass number 44 has four more neutrons than protons. This is an isotope of what element?

36. Identify the isotope X that has one more neutron than protons and a mass number equal to nine times the charge on the ion X^{3+}.

37. Iodine has many radioactive isotopes. Iodine-123 is a radioactive isotope used for obtaining images of the thyroid gland. Iodine-123 is administered to patients in the form of sodium iodide capsules that contain ${}^{123}\mathrm{I}^-$ ions. Determine the number of neutrons, protons, and electrons in a single ${}^{123}\mathrm{I}^-$ ion.

38. Iodine-131 is a radioactive isotope that has important medical uses. Small doses of iodine-131 are used for treating hyperthyroidism (overactive thyroid) and larger doses are used for treating thyroid cancer. Iodine-131 is administered to patients in the form of sodium iodide capsules that contain ${}^{131}\mathrm{I}^-$ ions. Determine the number of neutrons, protons, and electrons in a single ${}^{131}\mathrm{I}^-$ ion.

39. Americium-241 is a radioactive isotope that is used in high-precision gas and smoke detectors. How many neutrons, protons, and electrons are there in an atom of americium-241?

40. Some foods are made safer to eat by being exposed to gamma rays from radioactive isotopes, such as cobalt-60. The energy from the gamma rays kills bacteria in the food. How many neutrons, protons, and electrons are there in an atom of cobalt-60?

Atomic Mass Units, Atomic Masses

41. Which statement is probably true concerning the masses of *individual* chlorine atoms: *All have*, *some have*, or *none has* a mass of 35.4527 u? Explain.

42. The mass of a carbon-12 atom is taken to be exactly 12 u. Are there likely to be any other atoms with an *exact* integral (whole number) mass, expressed in u? Explain.

43. There are three naturally occurring isotopes of magnesium. Their masses and percent natural abundances are 23.985042 u, 78.99%; 24.985837 u, 10.00%; and 25.982593 u, 11.01%. Calculate the weighted-average atomic mass of magnesium.

44. There are four naturally occurring isotopes of chromium. Their masses and percent natural abundances are 49.9461 u, 4.35%; 51.9405 u, 83.79%; 52.9407 u, 9.50%; and 53.9389 u, 2.36%. Calculate the weighted-average atomic mass of chromium.

45. The two naturally occurring isotopes of silver have the following abundances: ^{107}Ag, 51.84%; ^{109}Ag, 48.16%. The mass of ^{107}Ag is 106.905092 u. What is the mass of ^{109}Ag?

46. Bromine has two naturally occurring isotopes. One of them, bromine-79, has a mass of 78.918336 u and a natural abundance of 50.69%. What must be the mass and percent natural abundance of the other isotope, bromine-81?

47. The three naturally occurring isotopes of potassium are ^{39}K, 38.963707 u; ^{40}K, 39.963999 u; and ^{41}K. The percent natural abundances of ^{39}K and ^{41}K are 93.2581% and 6.7302%, respectively. Determine the isotopic mass of ^{41}K.

48. What are the percent natural abundances of the two naturally occurring isotopes of boron, ^{10}B and ^{11}B? These isotopes have masses of 10.012937 u and 11.009305 u, respectively.

Mass Spectrometry

49. A mass spectrum of germanium displayed peaks at mass numbers 70, 72, 73, 74, and 76, with relative heights of 20.5, 27.4, 7.8, 36.5, and 7.8, respectively.
(a) In the manner of Figure 2-14, sketch this mass spectrum.
(b) Estimate the weighted-average atomic mass of germanium, and state why this result is only approximately correct.

50. Hydrogen and chlorine atoms react to form simple diatomic molecules in a 1:1 ratio, that is, HCl. The natural abundances of the chlorine isotopes are 75.77% ^{35}Cl and 24.23% ^{37}Cl. The natural abundances of ^{2}H and ^{3}H are 0.015% and less than 0.001%, respectively.
(a) How many different HCl molecules are possible, and what are their mass numbers (that is, the sum of the mass numbers of the H and Cl atoms)?
(b) Which is the most abundant of the possible HCl molecules? Which is the second most abundant?

The Periodic Table

51. Refer to the periodic table inside the front cover and identify
(a) the element that is in group 14 and the fourth period
(b) one element similar to and one unlike sulfur
(c) the alkali metal in the fifth period
(d) the halogen element in the sixth period

52. Refer to the periodic table inside the front cover and identify
(a) the element that is in group 11 and the sixth period
(b) an element with atomic number greater than 50 that has properties similar to the element with atomic number 18
(c) the group number of an element E that forms an ion E^{2-}
(d) an element M that you would expect to form the ion M^{3+}

53. Assuming that the seventh period of the periodic table has 32 members, what should be the atomic number of **(a)** the noble gas following radon (Rn); **(b)** the alkali metal following francium (Fr)?

54. Find the several pairs of elements that are “out of order” in terms of increasing atomic mass and explain why the reverse order is necessary.

The Avogadro Constant and the Mole

55. What is the total number of atoms in **(a)** 15.8 mol Fe; **(b)** 0.000467 mol Ag; **(c)** 8.5×10^{-11} mol Na?

56. *Without doing detailed calculations*, indicate which of the following quantities contains the greatest number of atoms: 6.022×10^{23} Ni atoms, 25.0 g nitrogen, 52.0 g Cr, 10.0 cm^3 Fe ($d = 7.86$ g/cm^3). Explain your reasoning.

57. Determine
(a) the number of moles of Zn in a 415.0 g sample of zinc metal

(b) the number of Cr atoms in 147.4 kg chromium
(c) the mass of a one-trillion-atom (1.0×10^{12}) sample of metallic gold
(d) the mass of one fluorine atom

58. Determine
(a) the number of Kr atoms in a 5.25-mg sample of krypton
(b) the molar mass, M, and identity of an element if the mass of a 2.80×10^{22}-atom sample of the element is 2.09 g
(c) the mass of a sample of phosphorus that contains the same number of atoms as 44.75 g of magnesium

59. How many Cu atoms are present in a piece of sterling-silver jewelry weighing 33.24 g? (Sterling silver is a silver–copper alloy containing 92.5% Ag by mass.)

60. How many atoms are present in a $75.0\ \text{cm}^3$ sample of plumber's solder, a lead–tin alloy containing 67% Pb by mass and having a density of $9.4\ \text{g/cm}^3$?

61. How many ^{204}Pb atoms are present in a piece of lead weighing 215 mg? The percent natural abundance of ^{204}Pb is 1.4%.

62. A particular lead–cadmium alloy is 8.0% cadmium by mass. What mass of this alloy, in grams, must you weigh out to obtain a sample containing 6.50×10^{23} Cd atoms?

63. Medical experts generally believe a level of 30 μg Pb per deciliter of blood poses a significant health risk (1 dL = 0.1 L). Express this level **(a)** in the unit mol Pb/L blood; **(b)** as the number of Pb atoms per milliliter blood.

64. During a severe episode of air pollution, the concentration of lead in the air was observed to be $3.01\ \mu\text{g Pb/m}^3$. How many Pb atoms would be present in a 0.500 L sample of this air (the approximate lung capacity of a human adult)?

65. *Without doing detailed calculations*, determine which of the following samples has the greatest number of atoms:
(a) a cube of iron with a length of 10.0 cm ($d = 7.86\ \text{g/cm}^3$)
(b) 1.00 kg of hydrogen contained in a 10,000 L balloon
(c) a mound of sulfur weighing 20.0 kg
(d) a 76 lb sample of liquid mercury ($d = 13.5\ \text{g/mL}$)

66. *Without doing detailed calculations*, determine which of the following samples occupies the largest volume:
(a) 25.5 mol of sodium metal ($d = 0.971\ \text{g/cm}^3$)
(b) 0.725 L of liquid bromine ($d = 3.12\ \text{g/mL}$)
(c) 1.25×10^{25} atoms of chromium metal ($d = 9.4\ \text{g/cm}^3$)
(d) 2.15 kg of plumber's solder ($d = 9.4\ \text{g/cm}^3$), a lead–tin alloy with a 2:1 atom ratio of lead to tin

Integrative and Advanced Exercises

67. A solution was prepared by dissolving 2.50 g potassium chlorate (a substance used in fireworks and flares) in 100.0 mL water at 40 °C. When the solution was cooled to 20 °C, its volume was still found to be 100.0 mL, but some of the potassium chlorate had crystallized (deposited from the solution as a solid). At 40 °C, the density of water is 0.9922 g/mL, and at 20 °C, the potassium chlorate solution had a density of 1.0085 g/mL.
(a) Estimate, to two significant figures, the mass of potassium perchlorate that crystallized.
(b) Why can't the answer in **(a)** be given more precisely?

68. William Prout (1815) proposed that all other atoms are built up of hydrogen atoms, suggesting that all elements should have integral atomic masses based on an atomic mass of one for hydrogen. This hypothesis appeared discredited by the discovery of atomic masses, such as 24.3 u for magnesium and 35.5 u for chlorine. In terms of modern knowledge, explain why Prout's hypothesis is actually quite reasonable.

69. Fluorine has a single atomic species, ^{19}F. Determine the atomic mass of ^{19}F by summing the masses of its protons, neutrons, and electrons, and compare your results with the value listed on the inside front cover. Explain why the agreement is poor.

70. Use 1×10^{-13} cm as the approximate diameter of the spherical nucleus of the hydrogen-1 atom, together with data from Table 2.1, to estimate the density of matter in a proton.

71. Use fundamental definitions and statements from Chapters 1 and 2 to establish the fact that $6.022 \times 10^{23}\ \text{u} = 1.000\ \text{g}$.

72. In each case, identify the element in question.
(a) The mass number of an atom is 234 and the atom has 60.0% more neutrons than protons.
(b) An ion with a 2+ charge has 10.0% more protons than electrons.
(c) An ion with a mass number of 110 and a 2+ charge has 25.0% more neutrons than electrons.

73. Determine the only possible 2+ ion for which the following two conditions are both satisfied:
- The net ionic charge is *one-tenth* the nuclear charge.
- The number of neutrons is *four* more than the number of electrons.

74. Determine the only possible isotope (E) for which the following conditions are met:
- The mass number of E is 2.50 times its atomic number.
- The atomic number of E is equal to the mass number of another isotope (Y). In turn, isotope Y has a neutron number that is 1.33 times the atomic number of Y and equal to the neutron number of selenium-82.

75. Suppose we redefined the atomic mass scale by arbitrarily assigning to the naturally occurring *mixture* of chlorine isotopes an atomic mass of 35.00000 u.
(a) What would be the atomic masses of helium, sodium, and iodine on this new atomic mass scale?

(b) Why do these three elements have nearly integral (whole-number) atomic masses based on carbon-12, but not based on naturally occurring chlorine?

76. The two naturally occurring isotopes of nitrogen have masses of 14.0031 and 15.0001 u, respectively. Determine the percentage of ^{15}N atoms in naturally occurring nitrogen.

77. The masses of the naturally occurring mercury isotopes are ^{196}Hg, 195.9658 u; ^{198}Hg, 197.9668 u; ^{199}Hg, 198.9683 u; ^{200}Hg, 199.9683 u; ^{201}Hg, 200.9703 u; ^{202}Hg, 201.9706 u; and ^{204}Hg, 203.9735 u. Use these data, together with data from Figure 2-14, to calculate the weighted-average atomic mass of mercury.

78. Germanium has three major naturally occurring isotopes: ^{70}Ge (69.92425 u, 20.85%), ^{72}Ge (71.92208 u, 27.54%), ^{74}Ge (73.92118 u, 36.29%). There are also two minor isotopes: ^{73}Ge (72.92346 u) and ^{76}Ge (75.92140 u). Calculate the percent natural abundances of the two minor isotopes. Comment on the precision of these calculations.

79. From the densities of the lines in the mass spectrum of krypton gas, the following observations were made:

- Somewhat more than 50% of the atoms were krypton-84.
- The numbers of krypton-82 and krypton-83 atoms were essentially equal.
- The number of krypton-86 atoms was 1.50 times as great as the number of krypton-82 atoms.
- The number of krypton-80 atoms was 19.6% of the number of krypton-82 atoms.
- The number of krypton-78 atoms was 3.0% of the number of krypton-82 atoms.

The masses of the isotopes are

^{78}Kr, 77.9204 u　^{80}Kr, 79.9164 u　^{82}Kr, 81.9135 u
^{83}Kr, 82.9141 u　^{84}Kr, 83.9115 u　^{86}Kr, 85.9106 u

The weighted-average atomic mass of Kr is 83.80. Use these data to calculate the percent natural abundances of the krypton isotopes.

80. The two naturally occurring isotopes of chlorine are ^{35}Cl (34.9689 u, 75.77%) and ^{37}Cl (36.9658 u, 24.23%). The two naturally occurring isotopes of bromine are ^{79}Br (78.9183 u, 50.69%) and ^{81}Br (80.9163 u, 49.31%). Chlorine and bromine combine to form bromine monochloride, BrCl. Sketch a mass spectrum for BrCl with the relative number of molecules plotted against molecular mass (similar to Figure 2-14).

81. How many atoms are present in a 1.00 m length of 20-gauge copper wire? A 20-gauge wire has a diameter of 0.03196 in., and the density of copper is 8.92 g/cm^3.

82. Monel metal is a corrosion-resistant copper–nickel alloy used in the electronics industry. A particular alloy with a density of 8.80 g/cm^3 and containing 0.022% Si by mass is used to make a rectangular plate 15.0 cm long, 12.5 cm wide, 3.00 mm thick, and has a 2.50 cm diameter hole drilled through its center. How many silicon-30 atoms are found in this plate? The mass of a silicon-30 atom is 29.97376 u, and the percent natural abundance of silicon-30 is 3.10%.

83. Deuterium, ^{2}H (2.0140 u), is sometimes used to replace the principal hydrogen isotope ^{1}H in chemical studies. The percent natural abundance of deuterium is 0.015%. If it can be done with 100% efficiency, what mass of naturally occurring hydrogen gas would have to be processed to obtain a sample containing 2.50×10^{21} ^{2}H atoms?

84. An alloy that melts at about the boiling point of water has Bi, Pb, and Sn atoms in the ratio 10:6:5, respectively. What mass of alloy contains a total of one mole of atoms?

85. A particular silver solder (used in the electronics industry to join electrical components) is to have the *atom* ratio of 5.00 Ag/4.00 Cu/1.00 Zn. What masses of the three metals must be melted together to prepare 1.00 kg of the solder?

86. A low-melting Sn–Pb–Cd alloy called *eutectic alloy* is analyzed. The *mole* ratio of tin to lead is 2.73:1.00, and the *mass* ratio of lead to cadmium is 1.78:1.00. What is the mass percent composition of this alloy?

87. In an experiment, 125 cm^3 of zinc and 125 cm^3 of iodine are mixed together and the iodine is completely converted to 164 cm^3 of zinc iodide. What volume of zinc remains unreacted? The densities of zinc, iodine, and zinc iodide are 7.13 g/cm^3, 4.93 g/cm^3, and 4.74 g/cm^3, respectively.

88. Atoms are spherical and so when silver atoms pack together to form silver metal, they cannot fill all the available space. In a sample of silver metal, approximately 26.0% of the sample is empty space. Given that the density of silver metal is 10.5 g/cm^3, what is the radius of a silver atom? Express your answer in picometers.

Feature Problems

89. The data Lavoisier obtained in the experiment described on page 35 are as follows:

Before heating: glass vessel + tin + air
= 13 onces, 2 gros, 2.50 grains

After heating: glass vessel + tin calx + remaining air
= 13 onces, 2 gros, 5.62 grains

How closely did Lavoisier's results conform to the law of conservation of mass? (1 livre = 16 onces; 1 once = 8 gros; 1 gros = 72 grains. In modern terms, 1 livre = 30.59 g.)

90. Some of Millikan's oil-drop data are shown on the next page. The measured quantities were not actual charges on oil drops but were proportional to these charges.

Show that these data are consistent with the idea of a fundamental electronic charge.

Observation	Measured Quantity	Observation	Measured Quantity
1	19.66	8	53.91
2	24.60	9	59.12
3	29.62	10	63.68
4	34.47	11	68.65
5	39.38	12	78.34
6	44.42	13	83.22
7	49.41		

91. Before 1961, the standard for atomic masses was the isotope ^{16}O, to which physicists assigned a value of exactly 16. At the same time, chemists assigned a value of exactly 16 to the naturally occurring mixture of the isotopes ^{16}O, ^{17}O, and ^{18}O. Would you expect atomic masses listed in a 60-year-old text to be the same, generally higher, or generally lower than in this text? Explain.

92. The German chemist Fritz Haber proposed paying off the reparations imposed against Germany after World War I by extracting gold from seawater. Given that (1) the amount of the reparations was $28.8 billion dollars, (2) the value of gold at the time was about $21.25 per troy ounce (1 troy ounce = 31.103 g), and (3) gold occurs in seawater to the extent of 4.67×10^{17} atoms per ton of seawater (1 ton = 2000 lb), how many cubic kilometers of seawater would have had to be processed to obtain the required amount of gold? Assume that the density of seawater is 1.03 g/cm^3. (Haber's scheme proved to be commercially infeasible, and the reparations were never fully paid.)

93. Mass spectrometry is one of the most versatile and powerful tools in chemical analysis because of its capacity to discriminate between atoms of different masses. When a sample containing a mixture of isotopes is introduced into a mass spectrometer, the ratio of the peaks observed reflects the ratio of the percent natural abundances of the isotopes. This ratio provides an internal standard from which the amount of a certain isotope present in a sample can be determined. This is accomplished by deliberately introducing a known quantity of a particular isotope into the sample to be analyzed. A comparison of the new isotope ratio to the first ratio allows the determination of the amount of the isotope present in the original sample.

An analysis was done on a rock sample to determine its rubidium content. The rubidium content of a portion of rock weighing 0.350 g was extracted, and to the extracted sample was added an additional 29.45 μg of ^{87}Rb. The mass spectrum of this spiked sample showed a ^{87}Rb peak that was 1.12 times as high as the peak for ^{85}Rb. Assuming that the two isotopes react identically, what is the Rb content of the rock (expressed in parts per million by mass)? The natural abundances and isotopic masses are shown in the table.

Isotope	% Natural Abundance	Atomic Mass, u
^{87}Rb	27.83	86.909
^{85}Rb	72.17	84.912

Self-Assessment Exercises

94. In your own words, define or explain these terms or symbols: **(a)** $^{A}_{Z}E$; **(b)** β particle; **(c)** isotope; **(d)** ^{16}O; **(e)** molar mass.

95. Briefly describe
- **(a)** the law of conservation of mass
- **(b)** Rutherford's nuclear atom
- **(c)** weighted-average atomic mass
- **(d)** a mass spectrum

96. Explain the important distinctions between each pair of terms:
- **(a)** cathode rays and X-rays
- **(b)** protons and neutrons
- **(c)** nuclear charge and ionic charge
- **(d)** periods and groups of the periodic table
- **(e)** metal and nonmetal
- **(f)** the Avogadro constant and the mole

97. When 10.0 g zinc and 8.0 g sulfur are allowed to react, all the zinc is consumed, 14.9 g zinc sulfide is produced, and the mass of unreacted sulfur remaining is
- **(a)** 2.0 g
- **(b)** 3.1 g
- **(c)** 4.9 g
- **(d)** impossible to predict from this information alone

98. One oxide of rubidium has 0.187 g O per gram of Rb. A possible O:Rb mass ratio for a second oxide of rubidium is **(a)** 16:85.5; **(b)** 8:42.7; **(c)** 1:2.674; **(d)** any of these.

99. Cathode rays
- **(a)** may be positively or negatively charged
- **(b)** are a form of electromagnetic radiation similar to visible light
- **(c)** have properties identical to β particles
- **(d)** have masses that depend on the cathode that emits them

100. The scattering of α particles by thin metal foils established that
- **(a)** the mass of an atom is concentrated in a positively charged nucleus
- **(b)** electrons are fundamental particles of all matter
- **(c)** all electrons carry the same charge
- **(d)** atoms are electrically neutral

101. Which of the following have the same charge and approximately the same mass?
(a) an electron and a proton; **(b)** a proton and a neutron; **(c)** a hydrogen atom and a proton; **(d)** a neutron and a hydrogen atom; **(e)** an electron and an H^- ion.

102. What is the correct symbol for the species that contains 18 neutrons, 17 protons, and 16 electrons?

103. The properties of magnesium will most resemble those of which of the following? **(a)** cesium; **(b)** sodium; **(c)** aluminum; **(d)** calcium; **(e)** manganese.

104. Which group in the main group of elements contains **(a)** no metals or metalloids? **(b)** only one metal or metalloid? **(c)** only one nonmetal? **(d)** only nonmetals?

105. The two species that have the same number of electrons as ^{32}S are **(a)** ^{32}Cl; **(b)** $^{34}S^{+}$; **(c)** $^{33}P^{+}$; **(d)** $^{28}Si^{2-}$; **(e)** $^{35}S^{2-}$; **(f)** $^{40}Ar^{2+}$; **(g)** $^{40}Ca^{2+}$.

106. To four significant figures, all of the following masses are possible for an individual titanium atom except one. The exception is **(a)** 45.95 u; **(b)** 46.95 u; **(c)** 47.87 u; **(d)** 47.95 u; **(e)** 48.95 u; **(f)** 49.94 u.

107. The mass of the isotope $^{84}_{36}Xe$ is 83.9115 u. If the atomic mass scale were redefined so that $^{84}_{36}Xe = 84$ u, *exactly*, the mass of the $^{12}_{6}C$ isotope would be **(a)** 11.9115 u; **(b)** 11.9874 u; **(c)** 12 u exactly; **(d)** 12.0127 u; **(e)** 12.0885 u.

108. A 5.585-kg sample of iron (Fe) contains
(a) 10.0 mol Fe
(b) twice as many atoms as does 600.6 g C
(c) 10 times as many atoms as does 52.00 g Cr
(d) 6.022×10^{24} atoms

109. There are three common iron-oxygen compounds. The one with the greatest proportion of iron has one Fe atom for every O atom and the formula FeO. A second compound has 2.327 g Fe per 1.000 g O, and the third has 2.618 g Fe per 1.000 g O. What are the formulas of these other two iron-oxygen compounds?

110. The four naturally occurring isotopes of strontium have the atomic masses 83.9134 u; 85.9093 u; 86.9089 u; and 87.9056 u. The percent natural abundance of the lightest isotope is 0.56% and of the heaviest, 82.58%. Estimate the percent natural abundances of the other two. Why is this result only a rough approximation?

111. Gold is present in seawater to the extent of 0.15 mg/ton. Assume the density of the seawater is 1.03 g/mL and determine how many Au atoms could conceivably be extracted from 0.250 L of seawater (1 ton = 2.000×10^{3} lb; 1 kg = 2.205 lb).

112. Appendix E describes a useful study aid known as concept mapping. Using the method presented in Appendix E, construct a concept map illustrating the different concepts in Sections 2-7 and 2-8.

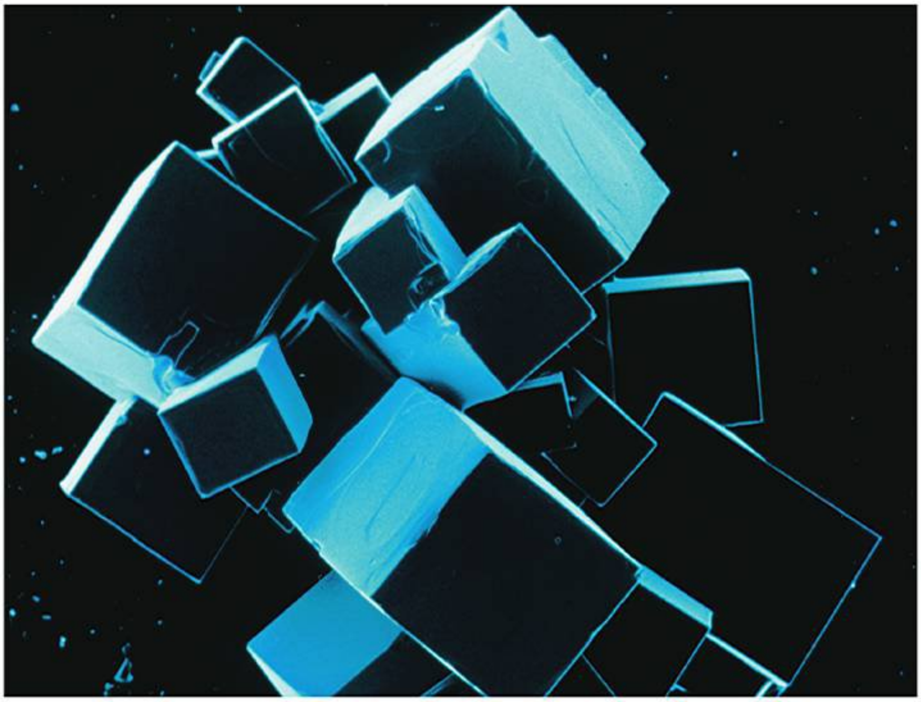
3-6 Names and Formulas of Inorganic Compounds
3-7 Names and Formulas of Organic Compounds



Scanning electron microscope image of sodium chloride crystals. Chemical compounds, their formulas, and their names are topics discussed in this chapter.

Water, ammonia, carbon monoxide, and carbon dioxide—all familiar substances—are rather simple chemical compounds. Only slightly less familiar are sucrose (cane sugar), acetylsalicylic acid (aspirin), and ascorbic acid (vitamin C). They too are chemical compounds. In fact, the study of chemistry is mostly about chemical compounds, and, in this chapter, we will consider a number of ideas about compounds.

The common feature of all compounds is that they are composed of two or more elements. The full range of compounds can be divided into a few broad categories by applying ideas from the periodic table of the elements. Compounds are represented by chemical formulas, which in turn are derived from the symbols of their constituent elements. In this chapter, you will learn how to deduce and write chemical formulas and how to use the information incorporated into chemical formulas. The chapter ends with an overview of the relationship between names and formulas—chemical nomenclature.

3-1 Types of Chemical Compounds and Their Formulas

Generally speaking, two fundamental kinds of chemical bonds hold together the atoms in a compound. *Covalent* bonds, which involve a sharing of electrons between atoms, give rise to molecular compounds. *Ionic* bonds, which involve a transfer of electrons from one atom to another, give rise to ionic compounds. In this section we consider only the basic features of molecular and ionic compounds that we need as background for the early chapters of the text. Our in-depth discussion of chemical bonding will come in Chapters 10 and 11.

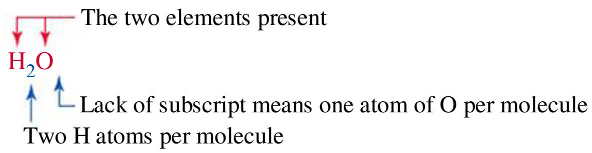
◀ In our later study of chemical bonding, we will find that the distinction between covalent and ionic bonding is not as clear-cut as these statements imply, but we will consider this matter in Chapter 10.

Molecular Compounds

A **molecular compound** is made up of discrete units called **molecules**, which typically consist of a small number of *nonmetal* atoms held together by covalent bonds. Molecular compounds are represented by **chemical formulas**, symbolic representations that, at minimum, indicate

- the elements present
- the relative number of atoms of each element

In the formula for water, the constituent elements are denoted by their symbols. The relative numbers of atoms are indicated by *subscripts*. Where no subscript is written, the number 1 is understood.

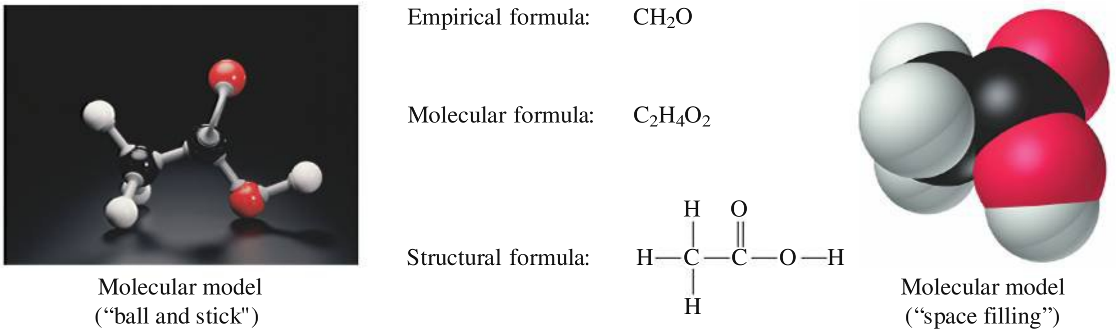


Another example of a chemical formula is CCl_4, which represents the compound carbon tetrachloride. The formulas H_2O and CCl_4 both represent distinct entities—*molecules*. Thus, we can refer to water and carbon tetrachloride as molecular compounds.

An **empirical formula** is the simplest formula for a compound; it shows the types of atoms present and their relative numbers. The subscripts in an empirical formula are reduced to their simplest whole-number ratio. For example, P_2O_5 is the empirical formula for a compound whose molecules have the formula P_4O_{10}. Generally, the empirical formula does not tell us a great deal about a compound. Acetic acid ($C_2H_4O_2$), formaldehyde (CH_2O, used to make certain plastics and resins), and glucose ($C_6H_{12}O_6$, blood sugar) all have the empirical formula CH_2O.

A **molecular formula** is based on an actual molecule of a compound. In some cases, the empirical and molecular formulas are identical, such as CH_2O for formaldehyde. In other cases, the molecular formula is a multiple of the empirical formula. A molecule of acetic acid, for example, consists of eight atoms—two C atoms, four H atoms, and two O atoms, so the molecular formula of acetic acid is $C_2H_4O_2$. This is twice the number of atoms in the formula unit (CH_2O). Empirical and molecular formulas tell us the combining ratio of the atoms in the compound, but they show nothing about how the atoms are attached to each other. Other types of formulas, however, do convey this information. Figure 3-1 shows several representations of acetic acid, the acid constituent that gives vinegar its sour taste.

A **structural formula** shows the order in which atoms are bonded together in a molecule and by what types of bonds. Thus, the structural formula of acetic acid tells us that three of the four H atoms are bonded to one of the C atoms, and the remaining H atom is bonded to an O atom. Both of the O atoms are bonded to one of the C atoms, and the two C atoms are bonded to each other. The covalent bonds in the structural formula are represented



Empirical formula: CH_2O
Molecular formula: $C_2H_4O_2$
Structural formula:
H O
H—C—C—O—H
H
Molecular model ("ball and stick")
Molecular model ("space filling")

▲ FIGURE 3-1
Several representations of the compound acetic acid
In the molecular model, the black spheres are carbon, the red are oxygen, and the white are hydrogen. To show that one H atom in the molecule is fundamentally different from the other three, the formula of acetic acid is often written as $HC_2H_3O_2$ (see Section 5-3). To show that this H atom is bonded to an O atom, the formulas CH_3COOH and CH_3CO_2H are also used. For a few chemical compounds, you may find different versions of chemical formulas in different sources.

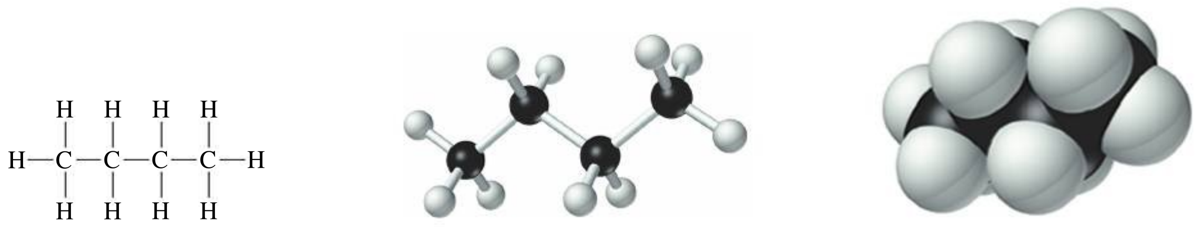
by lines or dashes (—). One of the bonds is represented by a double dash (═) and is called a *double* covalent bond. Differences between single and double bonds are discussed later in the text. For now, just think of a double bond as being a stronger or tighter bond than a single bond.

A **condensed structural formula**, which is written on a single line, is an alternative, less cumbersome way of showing how the atoms of a molecule are connected. Thus, the acetic acid molecule is represented as either CH_3COOH or CH_3CO_2H. With this type of formula, the different ways in which the H atoms are attached are still apparent.

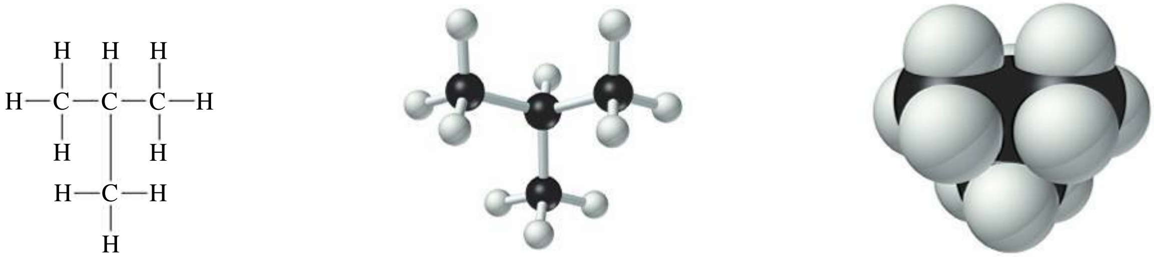
Condensed structural formulas can also be used to show how a group of atoms is attached to another atom. Consider methylpropane, C_4H_{10}, in Figure 3-2(b). The structural formula shows that there is a $—CH_3$ group of atoms attached to the central carbon atom. In the condensed structural formula, this is indicated by enclosing the CH_3 in parentheses to the right of the atom to which it is attached, thus $CH_3CH(CH_3)CH_3$. Alternatively, because the central C atom is bonded to each of the other three C atoms, we can write the condensed structural formula $CH(CH_3)_3$.

Organic compounds are made up principally of carbon and hydrogen, with oxygen and/or nitrogen as important constituents in many of them. Each carbon atom forms *four covalent bonds*. Organic compounds can be very complex, and one way of simplifying their structural formulas is to write structures without showing the C and H atoms explicitly. We do this by using a **line-angle formula** (also referred to as a *line structure*), in which lines represent chemical bonds. A carbon atom exists wherever a line ends or meets another line, and the number of H atoms needed to complete each carbon atom's four bonds are assumed to be present. The symbols of other atoms or groups of atoms and the bond lines joining them to C atoms are written explicitly. The formula of the complex male hormone molecule testosterone, seen in Figure 3-2(c), is a line-angle formula.

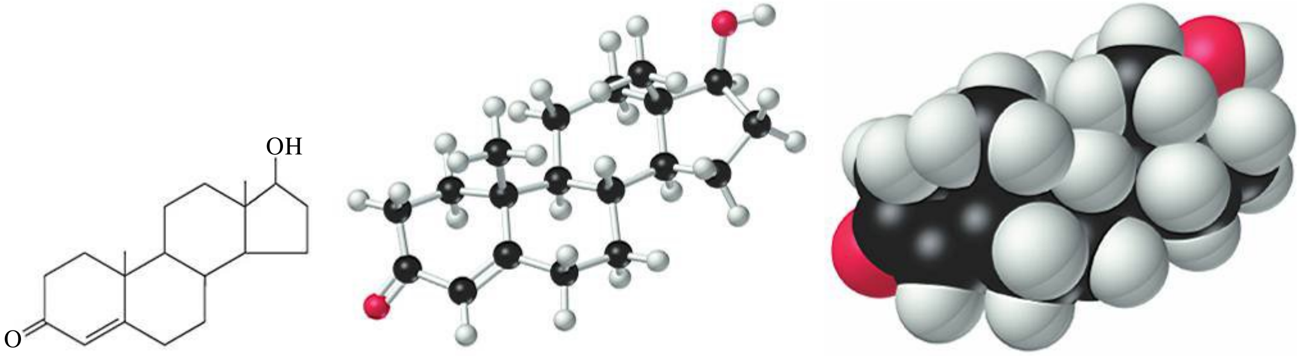
Molecules occupy space and have a three-dimensional shape, but empirical and molecular formulas do not convey any information about the spatial arrangements of atoms. Structural formulas can sometimes show this, but usually the only satisfactory way to represent the three-dimensional structure of molecules is with models. In a *ball-and-stick model*, atoms are represented by small balls, and the bonds between atoms by sticks (see Figure 3-1). Such models help us to visualize distances between the nuclei of atoms (bond lengths) and the geometrical shapes of molecules. Ball-and-stick models are easy to draw and interpret, but they can be somewhat misleading. Chemical bonds



(a) Butane



(b) Methylpropane



(c) Testosterone

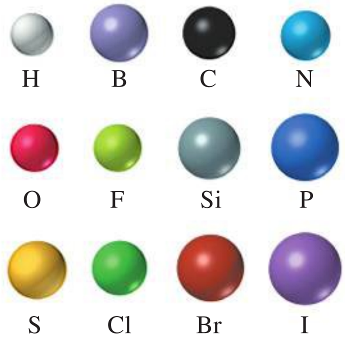
▲ FIGURE 3-2
Visualizations of (a) butane, (b) methylpropane, and (c) testosterone

are forces that draw atoms in a molecule into direct contact. The atoms are not held apart as implied by a ball-and-stick model.

A *space-filling model* shows that the atoms in a molecule occupy space and that they are in actual contact with one another. Certain computer programs generate images of space-filling models such as those shown in Figures 3-1 and 3-2. A space-filling model is a more accurate representation of the size and shape of a molecule because it is constructed to scale (that is, a nanometer-size molecule is magnified to a millimeter or centimeter scale).

The acetic acid molecule is made up of three types of atoms (C, H, and O) and models of the molecule reflect this fact. Different colors are used to distinguish the various types of atoms in ball-and-stick and space-filling models (see Fig. 3-3). You will notice that the colored spheres are of different sizes, which correspond to the size differences between the various atoms in the periodic table.

The various depictions of molecules just discussed will be used throughout this book. In fact, visualization of the sizes and shapes of molecules and interpretation of the physical and chemical properties in terms of molecular sizes and shapes is one of the most important aspects of modern chemistry.



▲ FIGURE 3-3
Color scheme for use in molecular models
The sizes of atoms, reflected in the various sizes of the colored spheres, are related to the locations of the elements in the periodic table, as discussed in Section 9-3.

3-1 CONCEPT ASSESSMENT

Represent the succinic acid molecule, $HOOCCH_2CH_2COOH$, through empirical, molecular, structural, and line-angle formulas.

Ionic Compounds

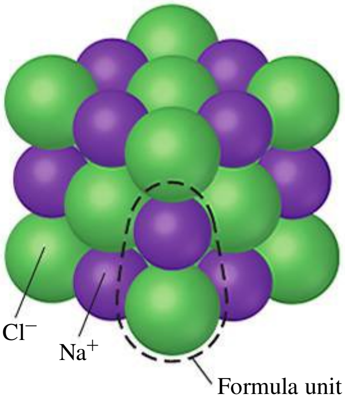
Chemical combination of a metal and a nonmetal usually results in an ionic compound. An **ionic compound** is made up of positive and negative ions joined together by electrostatic forces of attraction (recall the attraction of oppositely charged objects pictured in Figure 2-4). The atoms of metallic elements tend to lose one or more electrons when they combine with nonmetal atoms, and the nonmetal atoms tend to gain one or more electrons. As a result of this electron transfer, the metal atom becomes a positive ion, or **cation**, and the nonmetal atom becomes a negative ion, or **anion**. We can usually deduce the charge on a main-group cation or anion from the group of the periodic table to which the element belongs (recall Section 2-6). Thus the periodic table can help us to write the formulas of ionic compounds.

In the formation of sodium chloride—ordinary table salt—each sodium atom gives up one electron to become a sodium ion, Na^+, and each chlorine atom gains one electron to become a chloride ion, Cl^-. This fact conforms to the relationship between locations of the elements in the periodic table and the charges on their simple ions (see page 53). For sodium chloride to be electrically neutral, there must be one Na^+ ion for each Cl^- ion $(+1 - 1 = 0)$. Thus, the formula of sodium chloride is NaCl, and its structure is shown in Figure 3-4.

We observe that each Na^+ ion in sodium chloride is surrounded by six Cl^- ions, and vice versa, and we cannot say that any one of these six Cl^- ions belongs exclusively to a given Na^+ ion. Yet, the ratio of Cl^- to Na^+ ions in sodium chloride is 1 : 1, and so we arbitrarily select a combination of one Na^+ ion and one Cl^- ion as a formula unit. The **formula unit** of an ionic compound is the smallest electrically neutral collection of ions. The ratio of atoms (ions) in the formula unit is the same as in the chemical formula. Because it is buried in a vast network of ions, called a crystal, a formula unit of an ionic compound does not exist as a distinct entity. Thus it is inappropriate to call a formula unit of solid sodium chloride a molecule.

The situation with magnesium chloride is similar. In magnesium chloride, found in trace quantities in table salt, magnesium atoms lose two electrons to become magnesium ions, Mg^{2+} (Mg is in group 2). To obtain an electrically neutral formula unit, there must be two Cl^- ions, each with a charge of 1−, for every Mg^{2+} ion. The formula of magnesium chloride is $MgCl_2$.

The ions Na^+, Mg^{2+}, and Cl^- are *monatomic*, meaning that each consists of a single ionized atom. By contrast, a *polyatomic* ion is made up of two or more atoms. In the nitrate ion, NO_3^-, the subscripts signify that *three* O atoms and *one* N atom are joined by covalent bonds into the single ion NO_3^-. Magnesium nitrate is an ionic compound made up of magnesium and nitrate ions. An electrically neutral formula unit of this compound must consist of one Mg^{2+} ion and two NO_3^- ions. The formula based on this formula unit is denoted by enclosing NO_3 in parentheses, followed by the subscript 2; thus, $Mg(NO_3)_2$. Polyatomic ions are discussed further in Section 3-6.



▲ FIGURE 3-4
Portion of an ionic crystal and a formula unit of NaCl
Solid sodium chloride consists of enormous numbers of Na^+ and Cl^- ions in a network called a crystal. The combination of one Na^+ and one Cl^- ion is the smallest collection of ions from which we can deduce the formula NaCl. It is a formula unit.

3-1 ARE YOU WONDERING...

If a compound can be formed between different metal atoms?

In a metal, electrons of the atoms interact to form *metallic* bonds. The bonded atoms are usually of the same element, but they may also be of different elements, giving rise to *intermetallic* compounds. The metallic bond gives metals and intermetallic compounds their characteristic properties of electrical and heat conductivity. These bonds are described in Chapter 11.

3-2 The Mole Concept and Chemical Compounds

Once we know the chemical formula of a compound, we can determine its formula mass. **Formula mass** is the mass of a *formula unit* in atomic mass units. It is always appropriate to use the term formula mass, but, for a molecular compound, the formula unit is an actual molecule, so we can speak of molecular mass. **Molecular mass** is the mass of a **molecule** in atomic mass units.

◀ The terms *formula weight* and *molecular weight* are often used in place of formula mass and molecular mass. This is similar to the situation described for atomic mass and atomic weight in the footnote on page 48.

Weighted-average formula and molecular masses can be obtained just by adding up weighted-average atomic masses (those on the inside front cover). Thus, for the molecular compound water, H_2O,

$$\begin{aligned}\text{molecular mass } H_2O &= 2(\text{atomic mass H}) + (\text{atomic mass O})\\ &= 2(1.00794\ \text{u}) + 15.9994\ \text{u}\\ &= 18.0153\ \text{u}\end{aligned}$$

For the ionic compound magnesium chloride, $MgCl_2$,

$$\begin{aligned}\text{formula mass } MgCl_2 &= \text{atomic mass Mg} + 2(\text{atomic mass Cl})\\ &= 24.3050\ \text{u} + 2(35.453\ \text{u})\\ &= 95.211\ \text{u}\end{aligned}$$

and for the ionic compound magnesium nitrate, $Mg(NO_3)_2$,

$$\begin{aligned}\text{formula mass } Mg(NO_3)_2 &= \text{atomic mass Mg} + 2[\text{atomic mass N} + 3(\text{atomic mass O})]\\ &= 24.3050\ \text{u} + 2[14.0067\ \text{u} + 3(15.9994\ \text{u})]\\ &= 148.3148\ \text{u}\end{aligned}$$

◀ The terms *formula mass* and *molecular mass* have essentially the same meaning, although when referring to ionic compounds, such as NaCl and $MgCl_2$, formula mass is the proper term.

Mole of a Compound

Recall that in Chapter 2 a mole was defined as an amount of substance having the same number of elementary entities as there are atoms in exactly 12 g of pure carbon-12. This definition carefully avoids saying that the entities to be counted are always atoms. As a result, we can apply the concept of a mole to any quantity that we can represent by a symbol or formula—atoms, ions, formula units, or molecules. Specifically, a *mole of compound* is an amount of compound containing Avogadro's number (6.02214×10^{23}) of formula units or molecules. The **molar mass** is the mass of one mole of compound—one mole of molecules of a molecular compound and one mole of formula units of an ionic compound.

The weighted-average molecular mass of H_2O is 18.0153 u, compared with a mass of exactly 12 u for a carbon-12 atom. If we compare samples of water molecules and carbon atoms by using Avogadro's number of each, we get a mass of 18.0153 g H_2O, compared with exactly 12 g for carbon-12. The molar mass of H_2O is 18.0153 g H_2O/mol H_2O. If we know the formula of a compound, we can equate the following terms, as illustrated for H_2O, $MgCl_2$, and $Mg(NO_3)_2$.

$$\begin{aligned}1\ \text{mol } H_2O &= 18.0153\ \text{g } H_2O = 6.02214 \times 10^{23}\ H_2O\ \text{molecules}\\ 1\ \text{mol } MgCl_2 &= 95.211\ \text{g } MgCl_2 = 6.02214 \times 10^{23}\ MgCl_2\ \text{formula units}\\ 1\ \text{mol } Mg(NO_3)_2 &= 148.3148\ \text{g } Mg(NO_3)_2\\ &= 6.02214 \times 10^{23}\ Mg(NO_3)_2\ \text{formula units}\end{aligned}$$

KEEP IN MIND

that although *molecular mass* and *molar mass* sound similar and are related, they are not the same. Molecular mass is the weighted-average mass of one molecule expressed in atomic mass units, u. *Molar mass* is the mass of Avogadro's number of molecules expressed in grams per mole, g/mol. The two terms have the same numerical value but different units.

Such expressions as these provide several different types of conversion factors that can be applied in a variety of problem-solving situations. The strategy that works best for a particular problem will depend, in part, on how the necessary conversions are visualized. As we learned in Section 2-7, the most direct link to an amount in moles is through a mass in grams, so generally the central focus of a problem is the conversion of a mass in grams to an amount in moles, or vice versa. This conversion must often be preceded or followed by other conversions involving volumes, densities, percentages, and so on. As we saw in Chapter 2, one helpful tool in problem solving is to establish a conversion pathway. In Table 3.1, we summarize the roles that density, molar mass, and the Avogadro constant play in a conversion pathway.

TABLE 3.1 Density, Molar Mass, and the Avogadro Constant as Conversion Factors

Density, *d*	converts from volume to mass
Molar mass, *M*	converts from mass to amount (mol)
Avogadro constant, N_A	converts from amount (mol) to elementary entities

EXAMPLE 3-1 Relating Molar Mass, the Avogadro Constant, and Formula Units of an Ionic Compound

An analytical balance can detect a mass of 0.1 mg. How many ions are present in this minimally detectable quantity of $MgCl_2$?

Analyze

The central focus is the conversion of a measured quantity, 0.1 mg $MgCl_2$, to an amount in moles. After making the mass conversion, mg $\longrightarrow$ g, we can use the molar mass to convert from mass to amount in moles. Then, with the Avogadro constant as a conversion factor, we can convert from amount in moles to number of formula units. The final factor we need is based on the fact that there are *three* ions (*one* Mg^{2+} and *two* Cl^-) per formula unit (fu) of $MgCl_2$. It is often helpful to map out a conversion pathway that starts with the information given and proceeds through a series of conversion factors to the information sought. For this problem, we can begin with milligrams of $MgCl_2$ and make the following conversions:

$$\text{mg} \longrightarrow \text{g} \longrightarrow \text{mol} \longrightarrow \text{fu} \longrightarrow \text{number of ions}$$

Solve

The required conversions can be carried out in a stepwise fashion (as was done in Example 2-9), or they can be combined into a single line calculation. To avoid having to write down intermediate results and to avoid rounding errors, we'll use a single line calculation this time.

$$\begin{aligned} ?\ \text{ions} &= 0.1\ \text{mg MgCl}_2 \times \frac{1\ \text{g MgCl}_2}{1000\ \text{mg MgCl}_2} \times \frac{1\ \text{mol MgCl}_2}{95\ \text{g MgCl}_2} \\ &\times \frac{6.0 \times 10^{23}\ \text{fu MgCl}_2}{1\ \text{mol MgCl}_2} \times \frac{3\ \text{ions}}{1\ \text{fu MgCl}_2} \\ &= 2 \times 10^{18}\ \text{ions} \end{aligned}$$

Assess

The mass of the sample (0.1 mg) is given with one significant figure, and so the final answer is rounded to one significant figure. In the calculation above, the molar mass of $MgCl_2$ and the Avogadro constant are rounded off to two significant figures, that is, with one more significant figure than in the measured quantity.

PRACTICE EXAMPLE A: How many grams of $MgCl_2$ would you need to obtain 5.0×10^{23} Cl^- ions?

PRACTICE EXAMPLE B: How many nitrate ions, NO_3^-, and how many oxygen atoms are present in 1.00 μg of magnesium nitrate, $Mg(NO_3)_2$?

EXAMPLE 3-2 Combining Several Factors in a Calculation Involving Molar Mass

The volatile liquid ethyl mercaptan, C_2H_6S, is one of the most odoriferous substances known. It is sometimes added to natural gas to make gas leaks detectable. How many C_2H_6S molecules are contained in a 1.0 μL sample? The density of liquid ethyl mercaptan is 0.84 g/mL.

Analyze

The central focus is again the conversion of a measured quantity to an amount in moles. Because the density is given in g/mL, it will be helpful to convert the measured volume to milliliters. Then, density can be used as a conversion factor to obtain the mass in grams, and the molar mass can then be used to convert mass to amount in moles. Finally, the Avogadro constant can be used to convert the amount in moles to the number of molecules. In summary, the conversion pathway is $\mu\text{L} \rightarrow \text{L} \rightarrow \text{g} \rightarrow \text{mol} \rightarrow \text{molecules}$.

Solve

As always, the required conversions can be combined into a single line calculation. However, it is instructive to break the calculation into three steps: (1) a conversion from volume to mass, (2) a conversion from mass to amount in moles, and (3) a conversion from amount in moles to molecules. These three steps emphasize, respectively, the roles played by density, molar mass, and the Avogadro constant in the conversion pathway. (See Table 3.1.)

Convert from volume to mass.

$$? \text{ g } C_2H_6S = 1.0\ \mu\text{L} \times \frac{1 \times 10^{-6}\ \text{L}}{1\ \mu\text{L}} \times \frac{1000\ \text{mL}}{1\ \text{L}} \times \frac{0.84\ \text{g } C_2H_6S}{1\ \text{mL}}$$
$$= 8.4 \times 10^{-4}\ \text{g } C_2H_6S$$

Convert from mass to amount in moles.

$$? \text{ mol } C_2H_6S = 8.4 \times 10^{-4}\ \text{g } C_2H_6S \times \frac{1\ \text{mol } C_2H_6S}{62.1\ \text{g } C_2H_6S}$$
$$= 1.4 \times 10^{-5}\ \text{mol } C_2H_6S$$

Convert from moles to molecules.

$$? \text{ molecules } C_2H_6S = 1.4 \times 10^{-5}\ \text{mol } C_2H_6S \times \frac{6.02 \times 10^{23}\ \text{molecules } C_2H_6S}{1\ \text{mol } C_2H_6S}$$
$$= 8.1 \times 10^{18}\ \text{molecules } C_2H_6S$$

Assess

Remember to store intermediate results in your calculator *without* rounding off. Round off at the end. The answer is rounded to two significant figures because the volume and density are given with two significant figures. Rounding errors are avoided if the required conversions are combined into a single line calculation.

$$? \text{ molecules } C_2H_6S = 1.0\ \mu\text{L} \times \frac{1 \times 10^{-6}\ \text{L}}{1\ \mu\text{L}} \times \frac{1000\ \text{mL}}{1\ \text{L}} \times \frac{0.84\ \text{g } C_2H_6S}{1\ \text{mL}}$$
$$\times \frac{1\ \text{mol } C_2H_6S}{62.1\ \text{g } C_2H_6S} \times \frac{6.02 \times 10^{23}\ \text{molecules } C_2H_6S}{1\ \text{mol } C_2H_6S}$$
$$= 8.1 \times 10^{18}\ \text{molecules } C_2H_6S$$

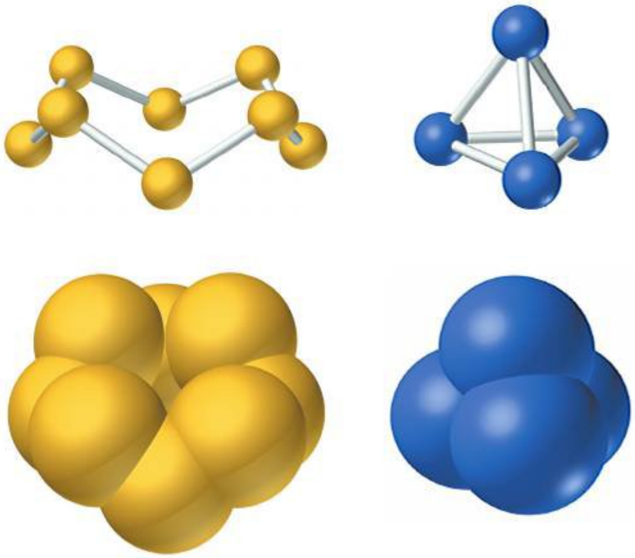
PRACTICE EXAMPLE A: Gold has a density of 19.32 g/cm^3. A piece of gold foil is 2.50 cm on each side and 0.100 mm thick. How many atoms of gold are in this piece of gold foil?

PRACTICE EXAMPLE B: If the 1.0 μL sample of liquid ethyl mercaptan from Example 3-2 is allowed to evaporate and distribute itself throughout a chemistry lecture room with dimensions 62 ft × 35 ft × 14 ft, will the odor of the vapor be detectable in the room? The limit of detectability is $9 \times 10^{-4}\ \mu\text{mol/m}^3$.

Mole of an Element—A Second Look

In Chapter 2, we took one mole of an element to be 6.02214×10^{23} *atoms* of the element. This is the only definition possible for such elements as iron, magnesium, sodium, and copper, in which enormous numbers of individual spherical atoms are clustered together, much like marbles in a can. But the atoms of some elements are joined together to form molecules. Bulk samples of these elements are composed of collections of molecules. The molecules of P_4 and S_8 are represented in Figure 3-5. The molecular formulas of elements that you should become familiar with are

$$H_2 \quad O_2 \quad N_2 \quad F_2 \quad Cl_2 \quad Br_2 \quad I_2 \quad P_4 \quad S_8$$



▶ FIGURE 3-5
Molecular forms of elemental sulfur and phosphorus
In a sample of solid sulfur, there are eight sulfur atoms in a sulfur molecule. In solid white phosphorus, there are four phosphorus atoms per molecule.

For these elements, we speak of an *atomic* mass or a *molecular* mass, and molar mass can be expressed in two ways. Hydrogen, for example, has an atomic mass of 1.00794 u and a molecular mass of 2.01588 u; its molar mass can be expressed as 1.00794 g H/mol H or 2.01588 g H_2/mol H_2.

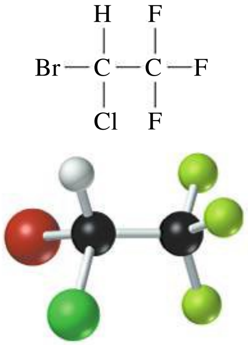
Another phenomenon occasionally encountered is the existence of an element in more than one molecular form, a situation referred to as *allotropy*. Thus, oxygen exists in two allotropic forms, the predominantly abundant diatomic oxygen, O_2, and the much less abundant allotrope *ozone*, O_3. The molar mass of ordinary dioxygen is 31.9988 g O_2/mol O_2, and that of ozone is 47.9982 g O_3/mol O_3.

3-2 CONCEPT ASSESSMENT

Without doing detailed calculations, determine which of the following quantities has the greatest mass and which has the smallest mass: (a) 0.50 mol O_2; (b) 2.0×10^{23} Cu atoms; (c) 1.0×10^{24} H_2O molecules; (d) a 20.000 g brass weight; (e) 1.0 mol Ne.

3-3 Composition of Chemical Compounds

▼ Two representations of halothane.



A chemical formula conveys considerable quantitative information about a compound and its constituent elements. We have already learned how to determine the molar mass of a compound, and, in this section, we consider some other types of calculations based on the chemical formula.

The colorless, volatile liquid halothane has been used as a fire extinguisher and also as an inhalation anesthetic. Both its empirical and molecular formulas are $C_2HBrClF_3$, its molecular mass is 197.382 u, and its molar mass is 197.382 g/mol, as calculated below:

$$\begin{aligned} M_{C_2HBrClF_3} &= 2M_C + M_H + M_{Br} + M_{Cl} + 3M_F \\ &= [(2 \times 12.0107) + 1.00794 + 79.904 + 35.453 + (3 \times 18.9984)]\ \text{g/mol} \\ &= 197.382\ \text{g/mol} \end{aligned}$$

The molecular formula of $C_2HBrClF_3$ tells us that *per mole* of halothane there are two moles of C atoms, one mole each of H, Br, and Cl atoms, and three moles of F atoms. This factual statement can be turned into conversion factors to answer such questions as, "How many C atoms are present per mole of halothane?" In this case, the factor needed is 2 mol C/mol $C_2HBrClF_3$. That is,

$$? \text{ C atoms} = 1.000 \text{ mol } C_2HBrClF_3 \times \frac{2 \text{ mol C}}{1 \text{ mol } C_2HBrClF_3} \times \frac{6.022 \times 10^{23} \text{ C atoms}}{1 \text{ mol C}}$$
$$= 1.204 \times 10^{24} \text{ C atoms}$$

In Example 3-3, we use another conversion factor derived from the formula for halothane. This factor is shown in blue in the setup, which includes other familiar factors to make the conversion pathway:

$$\text{mL} \longrightarrow \text{g} \longrightarrow \text{mol } C_2HBrClF_3 \longrightarrow \text{mol F}$$

EXAMPLE 3-3 Using Relationships Derived from a Chemical Formula

How many moles of F atoms are in a 75.0 mL sample of halothane ($d = 1.871$ g/mL)?

Analyze

The conversion pathway for this problem is given above. First, convert the volume of the sample to mass; this requires density as a conversion factor. Next, convert the mass of halothane to its amount in moles; this requires the inverse of the molar mass as a conversion factor. The final conversion factor is based on the formula of halothane.

Solve

$$? \text{ mol F} = 75.0 \text{ mL } C_2HBrClF_3 \times \frac{1.871 \text{ g } C_2HBrClF_3}{1 \text{ mL } C_2HBrClF_3}$$
$$\times \frac{1 \text{ mol } C_2HBrClF_3}{197.4 \text{ g } C_2HBrClF_3} \times \frac{3 \text{ mol F}}{1 \text{ mol } C_2HBrClF_3}$$
$$= 2.13 \text{ mol F}$$

Assess

If we had been asked for the number of moles of C instead, the final conversion factor in the calculation above would have been (2 mol C/1 mol $C_2HBrClF_3$).

PRACTICE EXAMPLE A: How many grams of Br are contained in 25.00 mL of halothane ($d = 1.871$ g/mL)?

PRACTICE EXAMPLE B: How many milliliters of halothane would contain 1.00×10^{24} Br atoms?

3-3 CONCEPT ASSESSMENT

In hexachlorophene, $C_{13}H_6Cl_6O_2$, a compound used in germicidal soaps, which element contributes the greatest number of atoms and which contributes the greatest mass?

Calculating Percent Composition from a Chemical Formula

When chemists believe that they have synthesized a new compound, a sample is generally sent to an analytical laboratory where its percent composition is determined. This experimentally determined percent composition is then compared with the percent composition calculated from the formula of the expected compound. In this way, chemists can see if the compound obtained could be the one expected.

Equation (3.1) establishes how the mass percent of an element in a compound is calculated. In applying the equation, as in Example 3-4, think in terms of the following steps.

1. **Determine the molar mass of the compound.** This is the *denominator* in equation (3.1).
2. **Determine the contribution of the given element to the molar mass**. This product of the formula subscript and the molar mass of the element appears in the *numerator* of equation (3.1).
3. **Formulate the ratio of the mass of the given element to the mass of the compound as a whole.** This is the ratio of the numerator from step 2 to the denominator from step 1.
4. **Multiply this ratio by 100% to obtain the mass percent of the element.**

$$\text{mass \% element} = \frac{\begin{pmatrix}\text{number of}\\ \text{atoms of element}\\ \text{per formula unit}\end{pmatrix} \times \begin{pmatrix}\text{molar mass}\\ \text{of element}\end{pmatrix}}{\text{molar mass of compound}} \times 100\% \tag{3.1}$$

The mass composition of a compound is the collection of mass percentages of the individual elements in the compound.

EXAMPLE 3-4 Calculating the Mass Percent Composition of a Compound

What is the mass percent composition of halothane, $C_2HBrClF_3$?

Analyze

Apply the four-step method described above. First, determine the molar mass of $C_2HBrClF_3$. Then formulate the mass ratios and convert them to mass percents. If we use molar masses that are rounded to two decimal places, the calculated mass percents will be accurate to two decimal places.

Solve

The molar mass of $C_2HBrClF_3$ is 197.38 g/mol. The mass percents are

$$\%\,\text{C} = \frac{\left(2\ \text{mol C} \times \dfrac{12.01\ \text{g C}}{1\ \text{mol C}}\right)}{197.38\ \text{g}\ C_2HBrClF_3} \times 100\% = 12.17\%\ \text{C}$$

$$\%\,\text{H} = \frac{\left(1\ \text{mol H} \times \dfrac{1.01\ \text{g H}}{1\ \text{mol H}}\right)}{197.38\ \text{g}\ C_2HBrClF_3} \times 100\% = 0.51\%\ \text{H}$$

$$\%\,\text{Br} = \frac{\left(1\ \text{mol Br} \times \dfrac{79.90\ \text{g Br}}{1\ \text{mol Br}}\right)}{197.38\ C_2HBrClF_3} \times 100\% = 40.48\%\ \text{Br}$$

$$\%\,\text{Cl} = \frac{\left(1\ \text{mol Cl} \times \dfrac{35.45\ \text{g Cl}}{1\ \text{mol Cl}}\right)}{197.38\ \text{g}\ C_2HBrClF_3} \times 100\% = 17.96\%\ \text{Cl}$$

$$\%\,\text{F} = \left(\frac{3\ \text{mol F} \times \dfrac{19.00\ \text{g F}}{1\ \text{mol F}}}{197.38\ \text{g}\ C_2HBrClF_3}\right) \times 100\% = 28.88\%\ \text{F}$$

Thus, the percent composition of halothane is 12.17% C, 0.51% H, 40.48% Br, 17.96% Cl, and 28.88% F.

Assess

The mass ratios appearing above are based on a sample that contains exactly *one mole* of halothane. Another approach is to calculate the mass of each element present in a sample that contains exactly *100* g of halothane. For example, in a *100 g* sample of halothane,

$$?\ \text{g C} = 100\ \text{g}\ C_2HBrClF_3 \times \frac{1\ \text{mol}\ C_2HBrClF_3}{197.38\ \text{g}\ C_2HBrClF_3} \times \frac{2\ \text{mol C}}{1\ \text{mol}\ C_2HBrClF_3} \times \frac{12.01\ \text{g C}}{1\ \text{mol C}} = 12.17\ \text{g C}$$

and so halothane is 12.17% C. The mass of carbon in a 100 g sample is numerically equal to the mass percent of carbon. If you compare the calculation of g C with that for % C given earlier, you will see that both calculations involve exactly the same factors but in a slightly different order.

PRACTICE EXAMPLE A: Adenosine triphosphate (ATP) is the main energy-storage molecule in cells. Its chemical formula is $C_{10}H_{16}N_5P_3O_{13}$. What is its mass percent composition?

PRACTICE EXAMPLE B: *Without doing detailed calculations*, determine which two compounds from the following list have the same percent oxygen by mass: **(a)** CO; **(b)** CH_3COOH; **(c)** C_2O_3; **(d)** N_2O; **(e)** $C_6H_{12}O_6$; **(f)** $HOCH_2CH_2OH$.

The percentages of the elements in a compound should add up to 100.00%, and we can use this fact in two ways.

1. Check the accuracy of the computations by ensuring that the percentages total 100.00%. As applied to the results of Example 3-4:

$$12.17\% + 0.51\% + 40.48\% + 17.96\% + 28.88\% = 100.00\%$$

2. Determine the percentages of all the elements but one. Obtain that one by difference (subtraction). From Example 3-4:

$$\begin{aligned} \%\,\text{H} &= 100.00\% - \%\,\text{C} - \%\,\text{Br} - \%\,\text{Cl} - \%\,\text{F} \\ &= 100.00\% - 12.17\% - 40.48\% - 17.96\% - 28.88\% \\ &= 0.51\% \end{aligned}$$

Establishing Formulas from the Experimentally Determined Percent Composition of Compounds

At times, a chemist isolates a chemical compound—say, from an exotic tropical plant—and has no idea what it is. A report from an analytical laboratory on the percent composition of the compound yields data needed to determine its formula.

Percent composition establishes the relative proportions of the elements in a compound on a *mass* basis. A chemical formula requires these proportions to be on a *mole* basis, that is, in terms of *numbers* of atoms. Consider the following five-step approach to determining a formula from the experimentally determined percent composition of the compound 2-deoxyribose, a sugar that is a basic constituent of DNA (deoxyribonucleic acid). The mass percent composition of 2-deoxyribose is 44.77% C, 7.52% H, and 47.71% O.

1. Although we could choose any sample size, if we take one of *exactly* 100 g, the masses of the elements are numerically equal to their percentages, that is, 44.77 g C, 7.52 g H, and 47.71 g O.
2. Convert the masses of the elements in the 100.00 g sample to amounts in moles.

$$?\ \text{mol C} = 44.77\ \text{g C} \times \frac{1\ \text{mol C}}{12.011\ \text{g C}} = 3.727\ \text{mol C}$$

$$?\ \text{mol H} = 7.52\ \text{g H} \times \frac{1\ \text{mol H}}{1.008\ \text{g H}} = 7.46\ \text{mol H}$$

$$?\ \text{mol O} = 47.71\ \text{g O} \times \frac{1\ \text{mol O}}{15.999\ \text{g O}} = 2.982\ \text{mol O}$$

◀ Use the molar mass with one more significant figure than in the mass of the element.

3. Write a tentative formula based on the numbers of moles just determined.

$$C_{3.727}H_{7.46}O_{2.982}$$

4. Attempt to convert the subscripts in the tentative formula to small whole numbers. This requires dividing each of the subscripts by the smallest one (2.982).

$$C_{\frac{3.727}{2.982}}\,H_{\frac{7.46}{2.982}}\,O_{\frac{2.982}{2.982}} = C_{1.25}H_{2.50}O$$

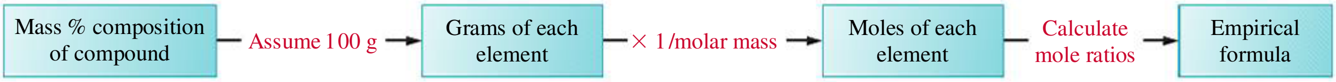
   If all subscripts at this point differ only slightly from whole numbers—which is not the case here—round them off to whole numbers, concluding the calculation at this point.

5. If one or more subscripts is still not a whole number—which is the case here—multiply all subscripts by a small whole number that will make them all integral. Thus, multiply by 4 here.

$$C_{(4\times1.25)}\,H_{(4\times2.50)}\,O_{(4\times1)} = C_5H_{10}O_4$$

The formula that we get by the method just outlined, $C_5H_{10}O_4$, is the simplest possible formula—the *empirical formula*. The actual *molecular formula* may be equal to, or some multiple of, the empirical formula, such as $C_{10}H_{20}O_8$, $C_{15}H_{30}O_{12}$, $C_{20}H_{40}O_{16}$, and so on. To find the multiplying factor, we must compare the formula mass based on the empirical formula with the true molecular mass of the compound. We can establish the molecular mass from a separate experiment (by methods introduced in Chapters 6 and 13). The experimentally determined molecular mass of 2-deoxyribose is 134 u. The formula mass based on the empirical formula, $C_5H_{10}O_4$, is 134.1 u. The measured molecular mass is the same as the empirical formula mass. The molecular formula is also $C_5H_{10}O_4$.

We outline the five-step approach described above in the flow diagram below and then apply the approach to Example 3-5, where we will find that the empirical formula and the molecular formula are not the same.



(3.2)

EXAMPLE 3-5 Determining the Empirical and Molecular Formulas of a Compound from Its Mass Percent Composition

Dibutyl succinate is an insect repellent used against household ants and roaches. Its composition is 62.58% C, 9.63% H, and 27.79% O. Its experimentally determined molecular mass is 230 u. What are the empirical and molecular formulas of dibutyl succinate?

Analyze

Use the five-step approach described above.

Solve

1. Determine the mass of each element in a 100.00 g sample.

   62.58 g C, 9.63 g H, 27.79 g O

2. Convert each of these masses to an amount in moles.

$$?\ \text{mol C} = 62.58\ \text{g C} \times \frac{1\ \text{mol C}}{12.011\ \text{g C}} = 5.210\ \text{mol C}$$

$$?\ \text{mol H} = 9.63\ \text{g H} \times \frac{1\ \text{mol H}}{1.008\ \text{g H}} = 9.55\ \text{mol H}$$

$$?\ \text{mol O} = 27.79\ \text{g O} \times \frac{1\ \text{mol O}}{15.999\ \text{g O}} = 1.737\ \text{mol O}$$

3. Write a tentative formula based on these numbers of moles.

   $C_{5.21}H_{9.55}O_{1.74}$

4. Divide each of the subscripts of the tentative formula by the smallest subscript (1.74),

$$C_{\frac{5.21}{1.74}}H_{\frac{9.55}{1.74}}O_{\frac{1.74}{1.74}} = C_{2.99}H_{5.49}O$$

and round off any subscripts that differ only slightly from whole numbers; that is, round 2.99 to 3.

$$C_3H_{5.49}O$$

5. Multiply all subscripts by a small whole number to make them integral (here by the factor 2), and write the empirical formula.

$$C_{2\times3}H_{2\times5.49}O_{2\times1} = C_6H_{10.98}O_2$$

$$2 \times 5.49 = 10.98 \approx 11$$

Empirical formula: $C_6H_{11}O_2$

To establish the molecular formula, first determine the empirical formula mass.

$$[(6 \times 12.0) + (11 \times 1.0) + (2 \times 16.0)]\text{u} = 115\text{ u}$$

Since the experimentally determined formula mass (230 u) is twice the empirical formula mass, the molecular formula is twice the empirical formula.

Molecular formula: $C_{12}H_{22}O_4$

Assess

Check the result by working the problem in reverse and using numbers that are rounded off slightly. For $C_{12}H_{22}O_4$, % C ≈ $(12 \times 12\text{ u}/230\text{ u}) \times 100\% = 63\%$; % H ≈ $(22 \times 1\text{ u}/230\text{ u}) \times 100\% = 9.6\%$; and % O ≈ $(4 \times 16\text{ u}/230\text{ u}) \times 100\% = 28\%$. The calculated mass percents agree well with those given in the problem, so we can be confident that our answer is correct.

PRACTICE EXAMPLE A: Sorbitol, used as a sweetener in some "sugar-free" foods, has a molecular mass of 182 u and a mass percent composition of 39.56% C, 7.74% H, and 52.70% O. What are the empirical and molecular formulas of sorbitol?

PRACTICE EXAMPLE B: The chlorine-containing narcotic drug pentaerythritol chloral has 21.51% C, 2.22% H, and 17.64% O, by mass, as its other elements. Its molecular mass is 726 u. What are the empirical and molecular formulas of pentaerythritol chloral?

3-4 CONCEPT ASSESSMENT

Explain why, if the percent composition *and* the molar mass of a compound are both known, the molecular formula can be determined much more readily by using the molar mass rather than a 100 g sample in the first step of the five-step procedure in Example 3-5. In this instance, how would you then obtain the empirical formula?

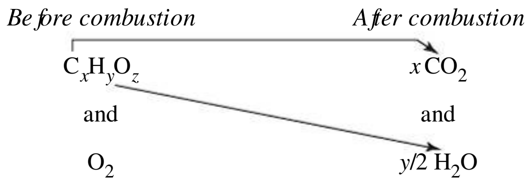
3-2 ARE YOU WONDERING...

How much rounding off to do to get integral subscripts in an empirical formula and what factors to use to convert fractional to whole numbers?

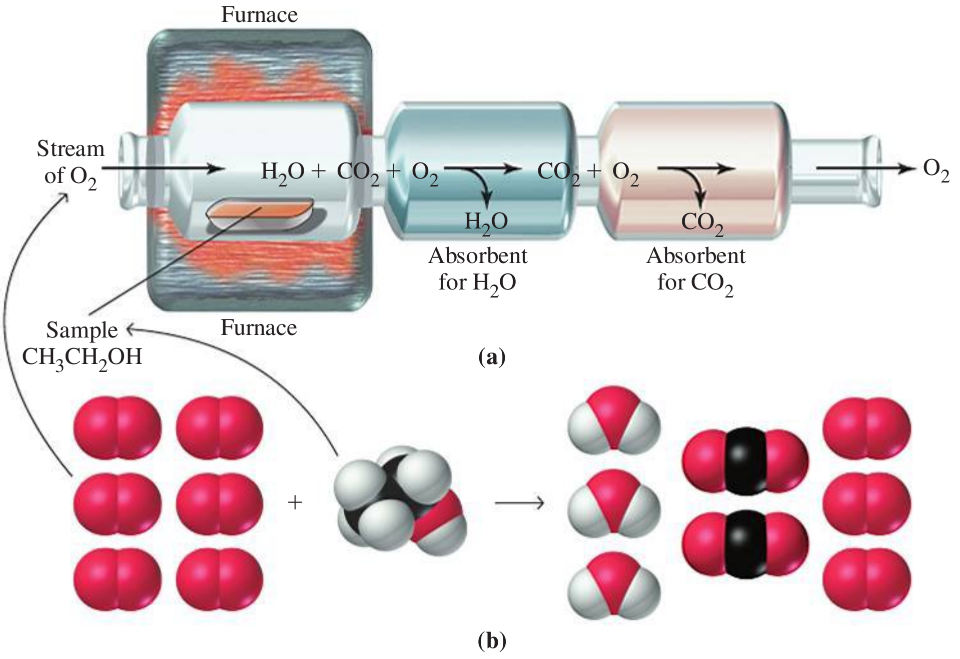
How much rounding off is justified depends on how precisely the elemental analysis is done. As a result, there is no ironclad rule on the matter. For the examples in this text, if you carry all the significant figures allowable in a calculation, you can generally round off a subscript that is within a few hundredths of a whole number (for example, 3.98 rounds off to 4). If the deviation is more than this, you will need to adjust subscripts to integral values by multiplying by the appropriate constant. If the appropriate constant is larger than a simple integer, such as 2, 3, 4, or 5, you may sometimes find it easier to make the adjustment by multiplying twice, for example, by 2 and then by 4 if the necessary constant is 8.

Combustion Analysis

Figure 3-6 illustrates an experimental method for establishing an empirical formula for compounds that are easily burned, such as compounds containing carbon and hydrogen with oxygen, nitrogen, and a few other elements. In *combustion analysis,* a weighed sample of a compound is burned in a stream of oxygen gas. The water vapor and carbon dioxide gas produced in the combustion are absorbed by appropriate substances. The increases in mass of these absorbers correspond to the masses of water and carbon dioxide. We can think of the matter as shown below. (The subscripts *x*, *y*, and *z* are integers whose values we do not know initially.)



After combustion, all the carbon atoms in the sample are found in the CO_2. All the H atoms are in the H_2O. Moreover, the only source of the carbon and hydrogen atoms was the sample being analyzed. Oxygen atoms in the CO_2 and H_2O could have come partly from the sample and partly from the oxygen gas consumed in the combustion. Thus, the quantity of oxygen in the sample has to be determined indirectly. These ideas are applied in Example 3-6.



▲ FIGURE 3-6

Apparatus for combustion analysis

(a) Oxygen gas passes through the combustion tube containing the sample being analyzed. This portion of the apparatus is enclosed in a high-temperature furnace. Products of the combustion are absorbed as they leave the furnace—water vapor by magnesium perchlorate, and carbon dioxide gas by sodium hydroxide (producing sodium carbonate). The differences in mass of the absorbers, after and before the combustion, yield the masses of H_2O and CO_2 produced in the combustion reaction. **(b)** A molecular picture of the combustion of ethanol. Each molecule of ethanol produces two CO_2 molecules and three H_2O molecules. Combustion takes place in an excess of oxygen, so that oxygen molecules are present at the end of the reaction. Note the conservation of mass.

EXAMPLE 3-6 Determining an Empirical Formula from Combustion Analysis Data

Vitamin C is essential for the prevention of scurvy. Combustion of a 0.2000 g sample of this carbon–hydrogen–oxygen compound yields 0.2998 g CO_2 and 0.0819 g H_2O. What are the percent composition and the empirical formula of vitamin C?

Analyze

After combustion, all the carbon atoms from the vitamin C sample are in CO_2 and all the hydrogen atoms are in H_2O. However, the oxygen atoms in CO_2 and H_2O come partly from the sample and partly from the oxygen gas consumed in the combustion. So, in the determination of the percent composition, we focus first on carbon and hydrogen and then on oxygen. To determine the empirical formula, we must calculate the amounts of C, H, and O in moles, and then calculate the mole ratios.

Solve

Percent Composition

First, determine the mass of carbon in 0.2988 g CO_2, by converting to mol C,

$$? \text{ mol C} = 0.2998 \text{ g } CO_2 \times \frac{1 \text{ mol } CO_2}{44.010 \text{ g } CO_2} \times \frac{1 \text{ mol C}}{1 \text{ mol } CO_2} = 0.006812 \text{ mol C}$$

and then to g C.

$$? \text{ g C} = 0.006812 \text{ mol C} \times \frac{12.011 \text{ g C}}{1 \text{ mol C}} = 0.08182 \text{ g C}$$

Proceed in a similar fashion for 0.0819 g H_2O to obtain

$$? \text{ mol H} = 0.0819 \text{ g } H_2O \times \frac{1 \text{ mol } H_2O}{18.02 \text{ g } H_2O} \times \frac{2 \text{ mol H}}{1 \text{ mol } H_2O} = 0.00909 \text{ mol H}$$

and

$$? \text{ g H} = 0.00909 \text{ mol H} \times \frac{1.008 \text{ g H}}{1 \text{ mol H}} = 0.00916 \text{ g H}$$

Obtain the mass of O in the 0.2000 g sample as the difference

$$? \text{ g O} = 0.2000 \text{ g sample} - 0.08182 \text{ g C} - 0.00916 \text{ g H} = 0.1090 \text{ g O}$$

Finally, multiply the mass fractions of the three elements by 100% to obtain mass percentages.

$$\% \text{ C} = \frac{0.08182 \text{ g C}}{0.2000 \text{ g sample}} \times 100\% = 40.91\% \text{ C}$$

$$\% \text{ H} = \frac{0.00916 \text{ g H}}{0.2000 \text{ g sample}} \times 100\% = 4.58\% \text{ H}$$

$$\% \text{ O} = \frac{0.1090 \text{ g O}}{0.2000 \text{ g sample}} \times 100\% = 54.50\% \text{ O}$$

Empirical Formula

At this point we can choose either of two alternatives. The first is to obtain the empirical formula from the mass percent composition, in the same manner illustrated in Example 3-5. The second is to note that we have already determined the number of moles of C and H in the 0.2000 g sample. The number of moles of O is

$$? \text{ mol O} = 0.1090 \text{ g O} \times \frac{1 \text{ mol O}}{15.999 \text{ g O}} = 0.006813 \text{ mol O}$$

From the numbers of moles of C, H, and O in the 0.2000 g sample, we obtain the tentative empirical formula

$$C_{0.006812}H_{0.00909}O_{0.006813}$$

Next, divide each subscript by the smallest (0.006812) to obtain

$$CH_{1.33}O$$

(continued)

Finally, multiply all the subscripts by 3 to obtain

Empirical formula of vitamin C: $C_3H_4O_3$

Assess

The determination of the empirical formula does not require determining the mass percent composition as a preliminary calculation. The empirical formula can be based on a sample of any size, as long as the numbers of moles of the different atoms in that sample can be determined.

PRACTICE EXAMPLE A: Isobutyl propionate is the substance that flavors rum extract. Combustion of a 1.152 g sample of this carbon–hydrogen–oxygen compound yields 2.726 g CO_2 and 1.116 g H_2O. What is the empirical formula of isobutyl propionate?

PRACTICE EXAMPLE B: Combustion of a 1.505 g sample of thiophene, a carbon–hydrogen–sulfur compound, yields 3.149 g CO_2, 0.645 g H_2O, and 1.146 g SO_2 as the only products of the combustion. What is the empirical formula of thiophene?

3-5 CONCEPT ASSESSMENT

When combustion is carried out in an excess of oxygen, the quantity producing the greatest mass of both CO_2 and H_2O is **(a)** 0.50 mol $C_{10}H_8$; **(b)** 1.25 mol CH_4; **(c)** 0.500 mol C_2H_5OH; **(d)** 1.00 mol C_6H_5OH.

We have just seen how combustion reactions can be used to analyze chemical substances, but not all samples can be easily burned. Fortunately, several other types of reactions can be used for chemical analyses. Also, modern methods in chemistry rely much more on physical measurements with instruments than on chemical reactions. We will cite some of these methods later in the text.

3-4 Oxidation States: A Useful Tool in Describing Chemical Compounds

▶ The oxidation state (O.S.) can be described as "a sometimes fictional charge." With monatomic ions, O.S. and charge are the same thing. For polyatomic ions and molecules, O.S. is fictional, but equal to what the charge would be if the compounds were entirely ionic.

Most basic concepts in chemistry deal with measurable properties or phenomena. In a few instances, though, a concept has been devised more for convenience than because of any fundamental significance. This is the case with the **oxidation state** (oxidation number),* which is related to the number of electrons that an atom loses, gains, or otherwise appears to use in joining with other atoms in compounds.

Consider NaCl. In this compound an Na atom, a metal, loses one electron to a Cl atom, a nonmetal. The compound consists of the ions Na^+ and Cl^- (see Figure 3-4). Na^+ is in a +1 oxidation state and Cl^- is in a −1 state.

In $MgCl_2$, an Mg atom loses two electrons to become Mg^{2+}, and each Cl atom gains one electron to become Cl^-. As in NaCl, the oxidation state of Cl is −1, but that of Mg is +2. If we take the *total* of the oxidation states of all the atoms (ions) in a formula unit of $MgCl_2$, we get $+2 - 1 - 1 = 0$.

In the molecule Cl_2, the two Cl atoms are identical and should have the same oxidation state. But if their total is to be zero, each oxidation state must itself be 0. Thus, the oxidation state of an atom can vary, depending on the compounds in which it occurs. In the molecule H_2O, we arbitrarily assign H the oxidation state of +1. Then, because the total of the oxidation states of the atoms must be zero, the oxidation state of oxygen must be −2.

---

*Because oxidation state refers to a number, the term oxidation number is often used synonymously. We will use the two terms interchangeably.

From these examples you can see that we need some conventions or rules for assigning oxidation states. The seven rules in Table 3.2 are sufficient to deal with most cases in this text, with this understanding: *The rules must be applied in the numerical order listed, and whenever two rules appear to contradict each other (which they sometimes will), follow the lower numbered rule.* Some examples are given for each rule, and the rules are applied in Example 3-7.

TABLE 3.2 Rules for Assigning Oxidation States

1. *The oxidation state (O.S.) of an individual atom in a free element (uncombined with other elements) is 0.*

[*Examples:* The O.S. of an isolated Cl atom is 0; the two Cl atoms in the molecule Cl_2 both have an O.S. of 0.]

2. *The total of the O.S. of all the atoms in*

- **(a)** *neutral species, such as isolated atoms, molecules, and formula units, is 0;*

  [*Examples:* The sum of the O.S. of all the atoms in CH_3OH and of all the ions in $MgCl_2$ is 0.]

- **(b)** *an ion is equal to the charge on the ion.*

  [*Examples:* The O.S. of Fe in Fe^{3+} is +3. The sum of the O.S. of all atoms in MnO_4^- is −1.]

3. *In their compounds, the group 1 metals have an O.S. of +1 and the group 2 metals have an O.S. of +2.*

[*Examples:* The O.S. of K is +1 in KCl and K_2CO_3; the O.S. of Mg is +2 in $MgBr_2$ and $Mg(NO_3)_2$.]

4. *In its compounds, the O.S. of fluorine is −1.*

[*Examples:* The O.S. of F is −1 in HF, ClF_3, and SF_6.]

5. *In its compounds, hydrogen usually has an O.S. of +1.*

[*Examples:* The O.S. of H is +1 in HI, H_2S, NH_3, and CH_4.]

6. *In its compounds, oxygen usually has an O.S. of −2.*

[*Examples:* The O.S. of O is −2 in H_2O, CO_2 and $KMnO_4$.]

7. *In binary (two-element) compounds with metals, group 17 elements have an O.S. of −1; group 16 elements, −2; and group 15 elements, −3.*

[*Examples:* The O.S. of Br is −1 in $MgBr_2$; the O.S. of S is −2 in Li_2S; and the O.S. of N is −3 in Li_3N.]

◀ The principal exceptions to rule 5 occur when H is bonded to metals, as in LiH, NaH, and CaH_2; exceptions to rule 6 occur in compounds with O—F bonds, such as OF_2, and in compounds where O atoms are bonded to one another, as in H_2O_2, and KO_2.

EXAMPLE 3-7 Assigning Oxidation States

What is the oxidation state of the underlined element in **(a)** $\underline{P}_4$; **(b)** $\underline{Al}_2O_3$; **(c)** $\underline{Mn}O_4^-$; **(d)** $Na\underline{H}$; **(e)** $H_2\underline{O}_2$; **(f)** $\underline{Fe}_3O_4$?

Analyze

Apply the rules in Table 3.2.

Solve

(a) P_4: This formula represents a molecule of elemental phosphorus. For an atom of a free element, the O.S. = 0 (rule 1). The O.S. of P in P_4 is 0.

(b) Al_2O_3: The total of the oxidation states of all the atoms in this formula unit is 0 (rule 2). The O.S. of oxygen is −2 (rule 6). The total for three O atoms is −6. The total for two Al atoms is +6. The O.S. of Al is +3.

(c) MnO_4^-: This is the formula for permanganate ion. The total of the oxidation states of all the atoms in the ion is −1 (rule 2). The total for the four O atoms is −8. The O.S. of Mn is +7.

(d) NaH: This is a formula unit of the ionic compound sodium hydride. Rule 3 states that the O.S. of Na is +1. Rule 5 indicates that H should also have an O.S. of +1. If both atoms had an O.S. of +1, the total for the formula unit would be +2. This violates rule 2. *Rules 2 and 3 take precedence over rule 5.* Na has an O.S. of +1; the total for the formula unit is 0; and the O.S. of H must be −1.

(continued)

(e) H_2O_2: This is hydrogen peroxide. Rule 5, stating that H has an O.S. of +1, takes precedence over rule 6 (which says that oxygen has an O.S. of −2). The sum of the oxidation states of the two H atoms is +2 and that of the two O atoms must be −2. The O.S. of O must be −1.

(f) Fe_3O_4: The total of the oxidation states of four O atoms is −8. For three Fe atoms, the total must be +8. The O.S. per Fe atom is $\frac{8}{3}$ or $+2\frac{2}{3}$.

Assess

With practice, you should be able to do the arithmetic associated with assigning oxidation states in your head, that is, without writing down any arithmetic expressions. Also, when you have determined an oxidation state by using arithmetic (as required by rule 2), check your result by making sure the sum of the oxidation states is equal to the charge on the atom, molecule, or ion. For example, in part **(c)**, we determined that the oxidation state of Mn in MnO_4^- is +7. We know this result is correct because the sum of the oxidation states is $7 + 4(-2) = -1$, which is equal to the charge on the MnO_4^- ion.

PRACTICE EXAMPLE A: What is the oxidation state of the underlined element in each of the following: $\underline{S}_8$; $\underline{Cr}_2O_7^{2-}$; $\underline{Cl}_2O$; $K\underline{O}_2$?

PRACTICE EXAMPLE B: What is the oxidation state of the underlined element in each of the following: $\underline{S}_2O_3^{2-}$; $\underline{Hg}_2Cl_2$; $K\underline{Mn}O_4$; $H_2\underline{C}O$?

In part (f) of Example 3-7, we got the somewhat surprising answer of $+2\frac{2}{3}$ for the oxidation state of the iron atoms in Fe_3O_4. Prior to that, we saw only integral values for oxidation states. How does this fractional value come about? Generally, it comes from the assumption that all the atoms of an element have the same oxidation state in a given compound. Usually they do, but not always. Fe_3O_4, for example, is probably better represented as $FeO \cdot Fe_2O_3$, that is, through a combination of two simpler formula units. In FeO, the O.S. of the Fe atom is +2. In Fe_2O_3, the O.S. of each of *two* Fe atoms is +3. When we *average* the oxidation states over all three Fe atoms, we get a nonintegral value: $(2 + 3 + 3)/3 = \frac{8}{3} = 2\frac{2}{3}$.

Also, we may at times need to "fragment" a formula into its constituent parts before assigning oxidation states. The ionic compound NH_4NO_3, for instance, consists of the ions NH_4^+ and NO_3^-. The oxidation state of N in NH_4^+ is −3, and in NO_3^-, +5, and we do *not* want to average them. It is far more useful to know the oxidation states of the individual N atoms than it is to deal with an average oxidation state of +1 for the two N atoms.

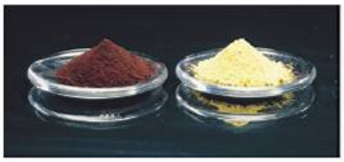
Our first use of oxidation states comes in the naming of chemical compounds in the next section.

3-6 CONCEPT ASSESSMENT

A nitrogen–hydrogen compound with molar mass 32 g/mol has N in a higher oxidation state than in NH_3. What is a plausible formula for that compound?

3-5 Naming Compounds: Organic and Inorganic Compounds

Throughout this chapter, we have referred to compounds mostly by their formulas, but we do need to give them names. When we know the name of a compound, we can look up its properties in a handbook, locate a chemical on a storeroom shelf, or discuss an experiment with a colleague. Later in the text we will see cases in which different compounds have the same formula. In these instances, we will find it essential to distinguish among compounds by name. We cannot give two substances the same name, yet we do want some similarities in the names of similar substances (Fig. 3-7). If all compounds were referred to by a common or trivial name, such as water (H_2O), ammonia (NH_3), or glucose



▲ FIGURE 3-7
Two oxides of lead
These two compounds contain the same elements—lead and oxygen—but in different proportions. Their names and formulas must convey this fact: lead(IV) oxide = PbO_2 (red-brown); lead(II) oxide = PbO (yellow).

($C_6H_{12}O_6$), we would have to learn millions of unrelated names—an impossibility. What we need is a systematic method of assigning names—a system of *nomenclature*. Several systems are used, and we will introduce each at an appropriate point in the text. Compounds formed by carbon and hydrogen or carbon and hydrogen together with oxygen, nitrogen, and a few other elements are **organic compounds**. They are generally considered in a special branch of chemistry—*organic chemistry*—that has its own set of nomenclature rules. Compounds that do not fit this description are **inorganic compounds**. The branch of chemistry that concerns itself with the study of these compounds is called *inorganic chemistry*. In the next section, we will consider the naming of inorganic compounds, and in Section 3-7, we will introduce the naming of organic compounds.

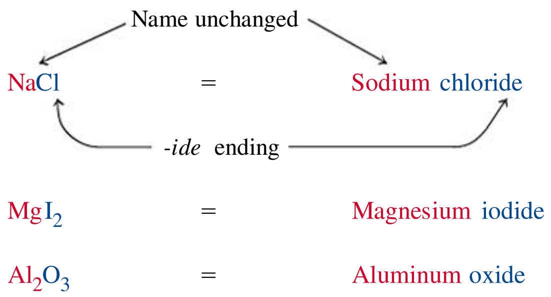
3-6 Names and Formulas of Inorganic Compounds

Binary Compounds of Metals and Nonmetals

Binary compounds are those formed between *two elements*. If one of the elements is a metal and the other a nonmetal, the binary compound is usually made up of ions; that is, it is a binary *ionic* compound. To name a binary compound of a metal and a nonmetal,

- write the *unmodified* name of the metal
- then write the name of the nonmetal, modified to end in *-ide*

The approach is illustrated below for NaCl, MgI_2, and Al_2O_3.



Ionic compounds, though made up of positive and negative ions, must be *electrically neutral*. The net, or total, charge of the ions in a formula unit must be zero. This means one Na^+ to one Cl^- in NaCl; one Mg^{2+} to two I^- in MgI_2; two Al^{3+} to three O^{2-} in Al_2O_3; and so on. Table 3.3 lists the names and symbols of simple ions formed by metals and nonmetals. You will find this list useful when writing names and formulas of binary compounds of metals and nonmetals. Because some metals may form several ions, it is important to distinguish between them in naming their compounds. The metal iron, for example, forms *two* common ions, Fe^{2+} and Fe^{3+}. The first is called the *iron(II)* ion, and the second is the *iron(III)* ion. The Roman numeral immediately following the name of the metal indicates its oxidation state or simply the charge on the ion. Thus, $FeCl_2$ is *iron(II)* chloride, while $FeCl_3$ is *iron(III)* chloride.

An earlier system of nomenclature that is still used to some extent applies two different word endings to distinguish between two binary compounds containing the same two elements but in different proportions, such as Cu_2O and CuO. In Cu_2O, the oxidation state of copper is +1, and in CuO it is +2. Cu_2O is assigned the name cupr*ous* oxide, and CuO is cupr*ic* oxide. Similarly, $FeCl_2$ is ferr*ous* chloride, and $FeCl_3$ is ferr*ic* chloride. The idea is to use the *-ous* ending for the lower oxidation state of the metal and *-ic* for the higher oxidation state. The *ous/ic* system has several inadequacies though, and we will not

▶ Table 3.3 simplifies considerably once you understand the pattern. All group 1 ions are 1+, group 2 ions are 2+, and Al^{3+}, Zn^{2+}, and Ag^{+} have only the one common charge. Most other metal ions have variable charges. Monatomic halogen ions are 1− and oxygen is 2−. Almost everything else can be worked out from these basics and the rule that the sum of all O.S. equals the total charge.

TABLE 3.3 Some Simple Ions

Name	Symbol	Name	Symbol
		Positive ions (cations)	
Lithium ion	Li^{+}	Chromium(II) ion	Cr^{2+}
Sodium ion	Na^{+}	Chromium(III) ion	Cr^{3+}
Potassium ion	K^{+}	Iron(II) ion	Fe^{2+}
Rubidium ion	Rb^{+}	Iron(III) ion	Fe^{3+}
Cesium ion	Cs^{+}	Cobalt(II) ion	Co^{2+}
Magnesium ion	Mg^{2+}	Cobalt(III) ion	Co^{3+}
Calcium ion	Ca^{2+}	Copper(I) ion	Cu^{+}
Strontium ion	Sr^{2+}	Copper(II) ion	Cu^{2+}
Barium ion	Ba^{2+}	Mercury(I) ion	Hg_2^{2+}
Aluminum ion	Al^{3+}	Mercury(II) ion	Hg^{2+}
Zinc ion	Zn^{2+}	Tin(II) ion	Sn^{2+}
Silver ion	Ag^{+}	Lead(II) ion	Pb^{2+}
		Negative ions (anions)	
Hydride ion	H^{-}	Iodide ion	I^{-}
Fluoride ion	F^{-}	Oxide ion	O^{2-}
Chloride ion	Cl^{-}	Sulfide ion	S^{2-}
Bromide ion	Br^{-}	Nitride ion	N^{3-}

use it in this text. For example, the -*ous* and -*ic* endings do not help in naming the four oxides of vanadium: VO, V_2O_3, VO_2, and V_2O_5.

Binary Compounds of Two Nonmetals

If the two elements in a binary compound are both nonmetals instead of a metal and a nonmetal, the compound is a molecular compound. The method of naming these compounds is similar to that just discussed. For example,

$$HCl = \text{hydrogen chloride}$$

In both the formula and the name, we write the element with the positive oxidation state first: HCl and *not* ClH.

EXAMPLE 3-8 Writing Formulas When Names of Compounds Are Given

Write formulas for the compounds barium oxide, calcium fluoride, and iron(III) sulfide.

Analyze

In each case, identify the cations and their charges, based on periodic table group numbers or on oxidation states appearing as Roman numerals in names: Ba^{2+}, Ca^{2+}, and Fe^{3+}. Then identify the anions and their charges: O^{2-}, F^{-}, and S^{2-}. Combine the cations and anions in the relative numbers required to produce electrically *neutral* formula units.

Solve

barium oxide: *one* Ba^{2+} and *one* O^{2-} = BaO
calcium fluoride: *one* Ca^{2+} and *two* F^{-} = CaF_2
iron(III) sulfide: *two* Fe^{3+} and *three* S^{2-} = Fe_2S_3

Assess

In the first case, an electrically neutral formula unit results from the combination of the charges 2+ and 2−; in the second case, 2+ and 2 × (1−); and in the third case, 2 × (3+) and 3 × (2−).

PRACTICE EXAMPLE A: Write formulas for lithium oxide, tin(II) fluoride, and lithium nitride.

PRACTICE EXAMPLE B: Write formulas for the compounds aluminum sulfide, magnesium nitride, and vanadium(III) oxide.

EXAMPLE 3-9 Naming Compounds When Their Formulas Are Given

Write acceptable names for the compounds Na_2S, AlF_3, Cu_2O.

Analyze

This task is generally easier than that of Example 3-8 because all you need to do is name the ions present. However, you must recognize that copper forms two different ions and that the cation in Cu_2O is Cu^+, copper(I).

Solve

Na_2S: sodium sulfide
AlF_3: aluminum fluoride
Cu_2O: copper(I) oxide

Assess

Knowing when to use Roman numerals and when not to use them is a tricky aspect of naming ionic compounds. Because the metals of groups 1 and 2 have only one ionic form (one oxidation state), Roman numerals are not used in naming their compounds.

PRACTICE EXAMPLE A: Write acceptable names for CsI, CaF_2, FeO, $CrCl_3$.

PRACTICE EXAMPLE B: Write acceptable names for CaH_2, CuCl, Ag_2S, Hg_2Cl_2.

Some pairs of nonmetals form more than one binary molecular compound, and we need to distinguish among them. Generally, we indicate relative numbers of atoms through *prefixes*: *mono* = 1, *di* = 2, *tri* = 3, *tetra* = 4, *penta* = 5, *hexa* = 6, *hepta* = 7, *octa* = 8, *nona* = 9, *deca* = 10, and so on. Thus, for the two principal oxides of sulfur we write

SO_2 = sulfur *di*oxide
SO_3 = sulfur *tri*oxide

and for the following boron–bromine compound

B_2Br_4 = *di*boron *tetra*bromide

Additional examples are given in Table 3.4. Note that in these examples the prefix *mono-* is treated in a special way. We do not use it for the first named

TABLE 3.4 Naming Binary Molecular Compounds

Formula	Name[a]
BCl_3	Boron trichloride
CCl_4	Carbon tetrachloride
CO	Carbon monoxide
CO_2	Carbon dioxide
NO	Nitrogen monoxide
NO_2	Nitrogen dioxide
N_2O	Dinitrogen monoxide
N_2O_3	Dinitrogen trioxide
N_2O_4	Dinitrogen tetroxide
N_2O_5	Dinitrogen pentoxide
PCl_3	Phosphorus trichloride
PCl_5	Phosphorus pentachloride
SF_6	Sulfur hexafluoride

[a] When the prefix ends in *a* or *o* and the element name begins with *a* or *o*, the final vowel of the prefix is dropped for ease of pronunciation. For example, carbon *mon*oxide, not carbon *mono*oxide, and dinitrogen *tetr*oxide, not dinitrogen *tetra*oxide. However, PI_3 is phosphorus *tri*iodide, not phosphorus *tri*odide.

element. Thus, NO is called nitrogen monoxide, *not* *mono*nitrogen *mono*xide. Finally, several substances have common or trivial names that are so well established that their systematic names are almost never used. For example,

H_2O = water (*di*hydrogen *mono*xide)
NH_3 = ammonia (H_3N = *tri*hydrogen *mono*nitride)

Binary Acids

Even though we use names like hydrogen chloride for pure binary molecular compounds, we sometimes want to emphasize that their aqueous solutions are acids. Acids will be discussed in detail later in the text. For now, so that we can recognize these substances and name them when we see their formulas, let us say that an *acid* is a substance that *ionizes* or breaks down in water to produce hydrogen ions (H^+)* and anions. A *binary acid* is a two-element compound of hydrogen and a nonmetal. For example, HCl ionizes into hydrogen ions (H^+) and chloride ions (Cl^-) in water; it is a binary acid. NH_3 in water is *not* an acid. It shows practically no tendency to produce H^+ under any conditions. NH_3 belongs to a complementary category of substances called *bases*. As we will see in Chapter 5, bases yield hydroxide ions (OH^-) in aqueous solutions.

In naming binary acids we use the prefix *hydro*- followed by the name of the other nonmetal modified with an *-ic* ending. The most important binary acids are listed below.

▶ The symbol (aq) signifies a substance in aqueous (water) solution.

HF(aq) = *hydro*fluor*ic* acid
HBr(aq) = *hydro*brom*ic* acid
HCl(aq) = *hydro*chlor*ic* acid
HI(aq) = *hydro*iod*ic* acid
H_2S(aq) = *hydro*sulfur*ic* acid

Polyatomic Ions

With the exception of Hg_2^{2+}, the ions listed in Table 3.3 are *monatomic*—each consists of a single atom. In **polyatomic ions**, two or more atoms are joined together by covalent bonds. These ions are common, especially among the nonmetals. A number of polyatomic ions and compounds containing them are listed in Table 3.5. From this table, you can see that

1. Polyatomic anions are more common than polyatomic cations. The most familiar polyatomic cation is the ammonium ion, NH_4^+.
2. Very few polyatomic anions carry the *-ide* ending in their names. Of those listed, only OH^- (hydroxide ion) and CN^- (cyanide ion) do. The common endings are *-ite* and *-ate*, and some names carry prefixes, *hypo-* or *per-*.
3. An element common to many polyatomic anions is *oxygen*, usually in combination with another nonmetal. Such anions are called **oxoanions**.
4. Certain nonmetals (such as Cl, N, P, and S) form a series of oxoanions containing different numbers of oxygen atoms. Their names are related to the oxidation state of the nonmetal atom to which the O atoms are bonded, ranging from *hypo-* (lowest) to *per-* (highest) according to the following scheme.

Increasing oxidation state of nonmetal →
*hypo*___*ite* ___*ite* ___*ate* *per*___*ate* **(3.3)**
Increasing number of oxygen atoms →

---

*The species produced in aqueous solution is actually more complex than the simple ion H^+. The H^+ combines with an H_2O molecule to produce an ion known as the hydronium ion, H_3O^+. Chemists often use H^+ for H_3O^+, and that is what we will do until we discuss this matter more fully in Chapter 5.

TABLE 3.5 Some Common Polyatomic Ions

Name	Formula	Typical Compound
Cation		
Ammonium ion	NH_4^+	NH_4Cl
Anions		
Acetate ion	CH_3COO^-	$NaCH_3COO$
Carbonate ion	CO_3^{2-}	Na_2CO_3
Hydrogen carbonate ion[a] (or bicarbonate ion)	HCO_3^-	$NaHCO_3$
Hypochlorite ion	ClO^-	$NaClO$
Chlorite ion	ClO_2^-	$NaClO_2$
Chlorate ion	ClO_3^-	$NaClO_3$
Perchlorate ion	ClO_4^-	$NaClO_4$
Chromate ion	CrO_4^{2-}	Na_2CrO_4
Dichromate ion	$Cr_2O_7^{2-}$	$Na_2Cr_2O_7$
Cyanide ion	CN^-	$NaCN$
Hydroxide ion	OH^-	$NaOH$
Nitrite ion	NO_2^-	$NaNO_2$
Nitrate ion	NO_3^-	$NaNO_3$
Oxalate ion	$C_2O_4^{2-}$	$Na_2C_2O_4$
Permanganate ion	MnO_4^-	$NaMnO_4$
Phosphate ion	PO_4^{3-}	Na_3PO_4
Hydrogen phosphate ion[a]	HPO_4^{2-}	Na_2HPO_4
Dihydrogen phosphate ion[a]	$H_2PO_4^-$	NaH_2PO_4
Sulfite ion	SO_3^{2-}	Na_2SO_3
Hydrogen sulfite ion[a] (or bisulfite ion)	HSO_3^-	$NaHSO_3$
Sulfate ion	SO_4^{2-}	Na_2SO_4
Hydrogen sulfate ion[a] (or bisulfate ion)	HSO_4^-	$NaHSO_4$
Thiosulfate ion	$S_2O_3^{2-}$	$Na_2S_2O_3$

[a] These anion names are sometimes written as a single word—for example, hydrogencarbonate, hydrogenphosphate, and so forth.

◀ Learn the most common ions first, such as NH_4^+, CO_3^{2-}, OH^-, NO_3^-, PO_4^{3-}, SO_4^{2-}, and ClO_3^-. When you understand the scheme in expression (3.3), the names of several others, such as NO_2^-, SO_3^{2-}, ClO^-, ClO_2^-, and ClO_4^- will become obvious. Over time, the rest will become more familiar to you.

5. All the common oxoanions of Cl, Br, and I carry a charge of 1−.
6. Some series of oxoanions also contain various numbers of H atoms and are named accordingly. For example, HPO_4^{2-} is the *hydrogen phosphate* ion and $H_2PO_4^-$, the *dihydrogen phosphate* ion.
7. The prefix *thio-* signifies that a sulfur atom has been substituted for an oxygen atom. (The sulfate ion has *one* S and *four* O atoms; thiosulfate ion has *two* S and *three* O atoms.)

Oxoacids

The majority of acids are **ternary compounds**. They contain *three* different elements—hydrogen and two other nonmetals. If one of the nonmetals is oxygen, the acid is called an **oxoacid**. Think of oxoacids as combinations of hydrogen ions (H^+) and oxoanions. The scheme for naming oxoacids is similar to that outlined for oxoanions, except that the ending *-ous* is used instead of *-ite* and *-ic* instead of *-ate*. Several oxoacids are listed in Table 3.6. Also listed are the names and formulas of compounds in which the hydrogen of the oxoacid has been replaced by a metal such as sodium. These compounds are called *salts*; we will say much more about them in later chapters, beginning in Chapter 5. Acids are molecular compounds, and salts are ionic compounds.

▶ When we refer to perchloric acid, for example, we generally mean an aqueous solution of $HClO_4$.

TABLE 3.6 Nomenclature of Some Oxoacids and Their Salts

Oxidation State	Formula of Acid[a]	Name of Acid[b]	Formula of Salt[b]	Name of Salt
Cl: +1	$HClO$	*Hypo*chlor*ous* acid	$NaClO$	Sodium *hypo*chlor*ite*
Cl: +3	$HClO_2$	Chlor*ous* acid	$NaClO_2$	Sodium chlor*ite*
Cl: +5	$HClO_3$	Chlor*ic* acid	$NaClO_3$	Sodium chlor*ate*
Cl: +7	$HClO_4$	*Per*chlor*ic* acid	$NaClO_4$	Sodium *per*chlor*ate*
N: +3	HNO_2	Nitr*ous* acid	$NaNO_2$	Sodium nitr*ite*
N: +5	HNO_3	Nitr*ic* acid	$NaNO_3$	Sodium nitr*ate*
S: +4	H_2SO_3	Sulfur*ous* acid	Na_2SO_3	Sodium sulf*ite*
S: +6	H_2SO_4	Sulfur*ic* acid	Na_2SO_4	Sodium sulf*ate*

[a] In all these acids, H atoms are bonded to O atoms, not the central nonmetal atom. Often formulas are written to reflect this fact, for instance, HOCl instead of HClO and HOClO instead of $HClO_2$.

[b] In general, the *-ic* and *-ate* names are assigned to compounds in which the central nonmetal atom has an oxidation state equal to the periodic table group number minus 10. Halogen compounds are exceptional in that the *-ic* and *-ate* names are assigned to compounds in which the halogen has an oxidation state of +5 (even though the group number is 17).

EXAMPLE 3-10 Applying Various Rules for Naming Compounds

Name the compounds **(a)** $CuCl_2$; **(b)** ClO_2; **(c)** HIO_4; **(d)** $Ca(H_2PO_4)_2$.

Analyze

$CuCl_2$ and $Ca(H_2PO_4)_2$ are ionic compounds. To name these compounds, we must identify and name the ions. ClO_2 and HIO_4 are molecular compounds. ClO_2 is a binary compound of two nonmetals and HIO_4 is an oxoacid.

Solve

(a) In this compound, the oxidation state of Cu is +2. Because Cu can also exist in the oxidation state of +1, we must clearly distinguish between the two possible chlorides. $CuCl_2$ is copper(II) chloride.

(b) Both Cl and O are nonmetals. ClO_2 is a binary molecular compound called chlorine dioxide.

(c) The oxidation state of I is +7. By analogy to the chlorine-containing oxoacids in Table 3.6, we should name this compound periodic acid (pronounced "purr-eye-oh-dic" acid).

(d) The polyatomic anion $H_2PO_4^-$ is dihydrogen phosphate ion. Two of these ions are present for every Ca^{2+} ion in the compound calcium dihydrogen phosphate.

Assess

A fair bit of memorization is associated with naming compounds correctly. Mastery of this subject usually requires a lot of practice.

PRACTICE EXAMPLE A: Name the compounds SF_6, HNO_2, $Ca(HCO_3)_2$, $FeSO_4$.

PRACTICE EXAMPLE B: Name the compounds NH_4NO_3, PCl_3, HBrO, $AgClO_4$, $Fe_2(SO_4)_3$.

Some Compounds of Greater Complexity

The copper compound that Joseph Proust used to establish the law of constant composition (page 36) is referred to in different ways. If you look up Proust's compound in a handbook of minerals, you will find it listed as *malachite*, with the formula $Cu_2(OH)_2CO_3$. In a handbook that specializes in pharmaceutical applications, this same compound is listed as *basic cupric carbonate*, with the formula $CH_2Cu_2O_5$. In a chemistry handbook, it is listed as *copper(II) carbonate dihydroxide*, with the formula $CuCO_3 \cdot Cu(OH)_2$. All you need to understand at this point is that regardless of the formula you use, you

▶ In general, centered dots (·) show that a formula is a composite of two or more simpler formulas.

EXAMPLE 3-11 Applying Various Rules in Writing Formulas

Write the formula of the compound **(a)** tetranitrogen tetrasulfide; **(b)** ammonium chromate; **(c)** bromic acid; **(d)** calcium hypochlorite.

Analyze

We must apply our knowledge of prefixes (such as *tetra-*) and endings (such as *-ic*), as well as the names of common polyatomic ions (such as *ammonium*, *chromate*, and *hypochlorite*).

Solve

(a) Molecules of this compound consist of *four* N atoms and *four* S atoms. The formula is N_4S_4.

(b) Two ammonium ions (NH_4^+) must be present for every chromate ion (CrO_4^{2-}). Place parentheses around NH_4^+, followed by the subscript 2. The formula is $(NH_4)_2CrO_4$. (This formula is read as "N-H-4, taken twice, C-R-O-4.")

(c) The *-ic* acid for the oxoacids of the halogens (group 17) has the halogen in the oxidation state of +5. Bromic acid is $HBrO_3$ (analogous to $HClO_3$ in Table 3.6).

(d) Here there are one Ca^{2+} and two ClO^- ions in a formula unit. This leads to the formula $Ca(ClO)_2$.

Assess

Notice that in writing formulas for compounds containing two or more polyatomic ions of the *same type*, as in **(b)** and **(d)**, we put parentheses around the formula of the ion (without the charge), followed by a subscript indicating the number of ions of that type. Proper use and placement of parentheses in writing formulas is important.

PRACTICE EXAMPLE A: Write formulas for the compounds **(a)** boron trifluoride, **(b)** potassium dichromate, **(c)** sulfuric acid, **(d)** calcium chloride.

PRACTICE EXAMPLE B: Write formulas for the compounds **(a)** aluminum nitrate, **(b)** tetraphosphorous decoxide, **(c)** chromium(III) hydroxide, **(d)** iodic acid.

should obtain the same molar mass (221.116 g/mol), the same mass percent copper (57.48% Cu), the same H : O mole ratio (2 mol H/5 mol O), and so on. In short, you should be able to interpret a formula, no matter how complex its appearance.

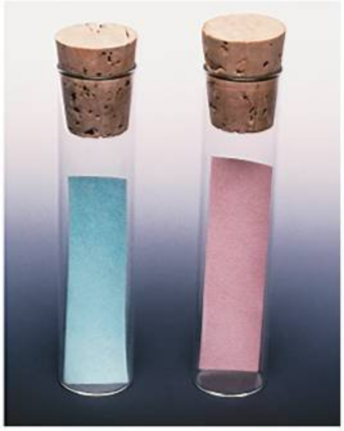
Some complex substances you are certain to encounter are known as hydrates. In a **hydrate**, each formula unit of the compound has associated with it a certain number of water molecules. This does not mean that the compounds are "wet," however. The water molecules are incorporated in the solid structure of the compound. The formula shown below signifies six H_2O molecules per formula unit of $CoCl_2$.

$$CoCl_2 \cdot 6\,H_2O$$

The prefix for six is *hexa-* and this compound is cobalt(II) chloride *hexa*hydrate. Its formula mass is that of $CoCl_2$ *plus* that associated with six H_2O: 129.839 u + (6 × 18.0153 u) = 237.931 u. We can speak of the mass percent water in a hydrate; for $CoCl_2 \cdot 6\,H_2O$ this is

$$\%\ H_2O = \frac{(6 \times 18.0153)\ g\ H_2O}{237.931\ g\ CoCl_2 \cdot 6\,H_2O} \times 100\% = 45.43\%$$

The water present in compounds as water of hydration can generally be removed, in part or totally, by heating. When the water is totally removed, the resulting compound is said to be *anhydrous* (without water). Anhydrous compounds can be used as water absorbers, as in the use of anhydrous magnesium perchlorate in combustion analysis (recall Figure 3-6). $CoCl_2$ gains and loses water quite readily and indicates this through a color change. Anhydrous $CoCl_2$ is blue, whereas the hexahydrate is pink. This fact can be used to make a simple moisture detector (Fig. 3-8).



▲ FIGURE 3-8
Effect of moisture on $CoCl_2$
The piece of filter paper was soaked in a water solution of cobalt(II) chloride and then allowed to dry. When kept in dry air, the paper is blue in color (anhydrous $CoCl_2$). In humid air, the paper changes to pink ($CoCl_2 \cdot 6\,H_2O$).

3-7 Names and Formulas of Organic Compounds

Organic compounds abound in nature. The foods we eat are made up almost exclusively of organic compounds, including not only energy-producing fats and carbohydrates and muscle-building proteins but also trace compounds that impart color, odor, and flavor to these foods. Almost all fuels, whether used to power automobiles, trucks, trains, or airplanes, are mixtures of organic compounds of a type called hydrocarbons. Most of the drugs produced by pharmaceutical companies are complex organic compounds, as are common plastics. The multiplicity of organic compounds is so vast that *organic chemistry* exists as a distinctive field of chemistry.

The great diversity of organic compounds arises from the ability of carbon atoms to combine readily with other carbon atoms and with atoms of a number of other elements. Carbon atoms join together to form a framework of chains or rings to which other atoms are attached. All organic compounds contain carbon atoms; almost all contain hydrogen atoms; and many common ones also have oxygen, nitrogen, or sulfur atoms. These possibilities allow for an almost limitless number of different organic compounds. Organic compounds are mostly molecular; a few are ionic.

KEEP IN MIND

that each carbon atom forms four covalent bonds.

There are millions of organic compounds, many comprising highly complex molecules. Their names are equally complicated. A systematic approach to naming these compounds is crucial, and the rules for naming inorganic compounds are of little use here. The usual name, often called the common or *trivial* name, for a familiar sweetener is sucrose (sugar). The systematic name is α-D-glucopyranosyl-β-D-fructofuranoside. At this point, however, we only need to recognize organic compounds and use their common names, together with an occasional systematic name. We will look at the systematic nomenclature of organic compounds in more detail in Chapter 26.

Hydrocarbons

Compounds containing only carbon and hydrogen are called **hydrocarbons**. The simplest hydrocarbon contains one carbon atom and four hydrogen atoms—methane, CH_4 (Fig. 3-9a). As the number of carbon atoms increases, the number of hydrogen atoms also increases in a systematic way, depending on the type of hydrocarbon. The complexity of organic chemistry arises because carbon atoms can form chains and rings, and the nature of the chemical bonds between the carbon atoms can vary. Hydrocarbons containing only single bonds are called **alkanes**. The simplest alkane is methane, followed by ethane, C_2H_6 (Fig. 3-9b), and then propane, C_3H_8 (Fig. 3-9c). The fourth member of the series, butane, C_4H_{10}, was shown in Figure 3-2(a). Notice that each succeeding member of the alkane series is formed by the addition of one C atom and two H atoms to the preceding member.

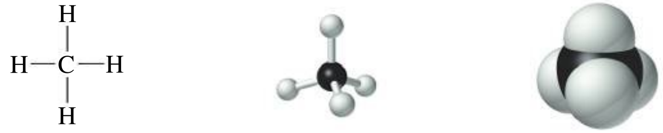
The names of the alkanes are composed of two parts: a word stem and the ending (suffix) *-ane* indicating that the molecule is an *alkane*. The first four word stems in Table 3.7 reflect common names, while the rest indicate the number of carbon atoms in the alkane. Thus C_5H_{12} is pentane and C_7H_{16} is heptane (hept = 7).

TABLE 3.7 Word Stem (or Prefix) Indicating the Number of Carbon Atoms in Simple Organic Molecules

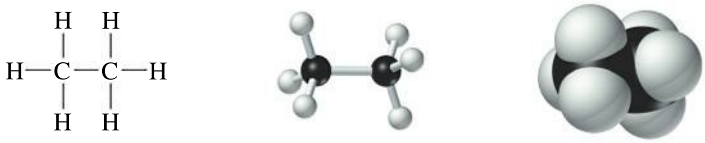
Stem (or prefix)	Number of C Atoms
Meth-	1
Eth-	2
Prop-	3
But-	4
Pent-	5
Hex-	6
Hept-	7
Oct-	8
Non-	9
Dec-	10

Hydrocarbon molecules with one or more double bonds between carbon atoms are called *alkenes*. The simplest of the alkenes is ethene (Fig. 3-9d); its name consists of the stem *eth-* and the ending *-ene*. Benzene, C_6H_6 (Fig. 3-9e), is a molecule with six carbon atoms arranged in a hexagonal ring. Molecules with structures related to benzene make up a large proportion of known organic compounds.

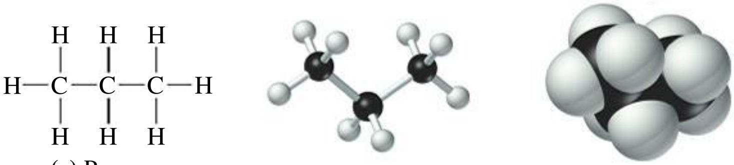
Refer to Figure 3-2 (page 71) and you will notice that butane and methylpropane have the same molecular formula, C_4H_{10}, but different structural formulas. Butane is based on a four-carbon chain, whereas in methylpropane, a



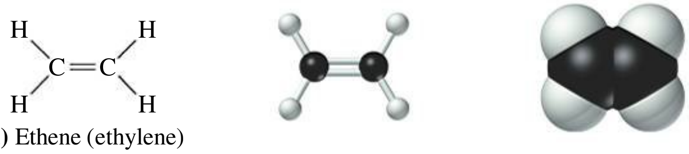
(a) Methane



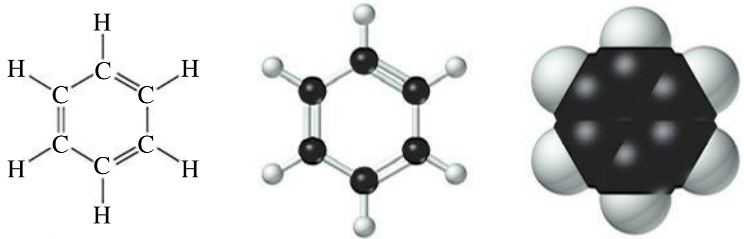
(b) Ethane



(c) Propane



(d) Ethene (ethylene)



(e) Benzene

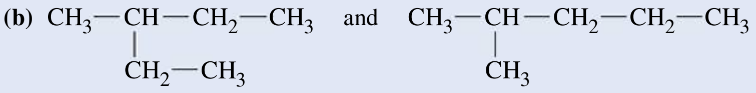
◀ FIGURE 3-9
Visualizations of some hydrocarbons

$—CH_3$ group, called a *methyl* group, is attached to the middle carbon atom of the three-carbon propane chain. Butane and methylpropane are *isomers*. **Isomers** are molecules that have the same molecular formula but different arrangements of atoms in space. As organic molecules become more complex, the possibilities for isomerism increase very rapidly.

EXAMPLE 3-12 Recognizing Isomers

Are the following pairs of molecules isomers or not?

(a) $CH_3CH(CH_3)(CH_2)_3CH_3$ and $CH_3CH_2CH(CH_3)(CH_2)_3CH_3$



(b) $CH_3—\underset{\displaystyle CH_2—CH_3}{\underset{|}{CH}}—CH_2—CH_3$ and $CH_3—\underset{\displaystyle CH_3}{\underset{|}{CH}}—CH_2—CH_2—CH_3$

Analyze

Isomers have the same molecular formula but different structures. We first check to see if the molecular formulas are the same. If the formulas are not the same, they represent different compounds. If the formulas are the same, the compounds *may* be isomers, but only if their structures are different.

Solve

(a) The molecular formula of the first compound is C_7H_{16}, while that of the second compound is C_8H_{18}. The molecules are not isomers.

(continued)

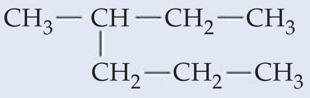
(b) These molecules have the same formula, C_6H_{14}, but they differ in structure. They are isomers. The difference in structure is that in the first structure, a methyl side chain is on the middle carbon atom of a five-carbon chain, and in the second structure it is on the second carbon atom from the end of the chain.

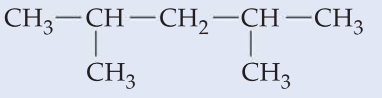
Assess

The compounds shown in part **(a)** have different molecular formulas and, thus, are clearly different compounds. We expect these compounds to have markedly different properties. The compounds shown in part **(b)** have the same molecular formula but different molecular structures. They are different compounds and have different properties. For example, the compound shown on the left in part **(b)** has a slightly higher boiling point than the compound shown on the right (63 °C versus 60 °C).

PRACTICE EXAMPLE A: Are the following pairs of molecules isomers?

(a) $CH_3C(CH_3)_2(CH_2)_3CH_3$ and $CH_3CH(CH_3)CH(CH_3)(CH_2)_3CH_3$

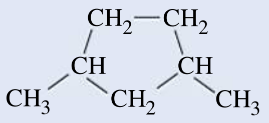
(b)


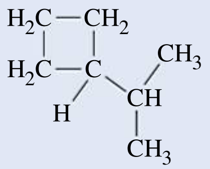
$CH_3-\underset{\underset{\displaystyle CH_2-CH_2-CH_3}{|}}{CH}-CH_2-CH_3$
and


$CH_3-\underset{\underset{\displaystyle CH_3}{|}}{CH}-CH_2-\underset{\underset{\displaystyle CH_3}{|}}{CH}-CH_3$

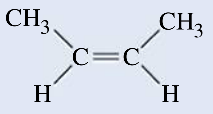
PRACTICE EXAMPLE B: Are the pairs of molecules represented by the following structural formulas isomers?

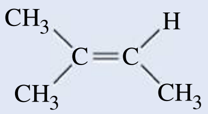
(a)





(b)





3-7 CONCEPT ASSESSMENT

In the combustion of a hydrocarbon, can the mass of H_2O produced ever exceed that of the CO_2? Explain.

Functional Groups

Carbon chains provide the framework of organic compounds; other atoms or groups of atoms replace one or more of the hydrogen atoms to form different compounds. We can illustrate this with the common alcohol molecule that occurs in beer, wine, and spirits. The molecule is *ethanol*, CH_3CH_2OH, in which one of the H atoms of ethane is replaced by an $-OH$ group (Fig. 3.10a). The systematic name ethanol is derived from the name of the alkane, ethane, with the final *-e* replaced by the suffix *-ol*. The suffix *-ol* designates the presence of the OH group in a class of organic molecules called **alcohols**.

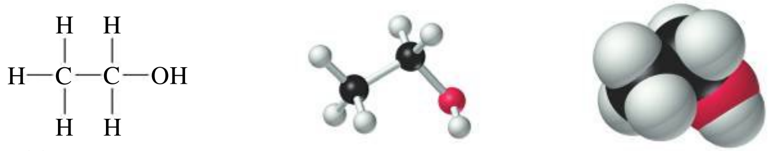
KEEP IN MIND

that alcohols are covalently bonded molecular compounds in which oxygen atoms are covalently bonded to carbon atoms. They are not ionic compounds that contain hydroxide ions.

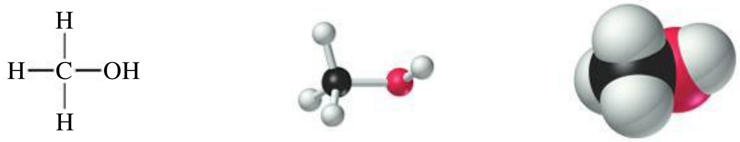
Ethyl alcohol, the common name of ethanol, also indicates attachment of the $-OH$ group to the ethane hydrocarbon chain. To name the alkane chain as a group, replace the final *-e* with *-yl*, so that ethane becomes *ethyl*, thus *ethyl alcohol* for CH_3CH_2OH. It is often the case that the common name of one compound, alcohol in this case, will provide the generic name for a complete class of compounds; that is, all alcohols contain at least one $-OH$ group.

Another common alcohol is *methanol*, or wood alcohol, which has the formula CH_3OH (Fig. 3.10b). The common name for methanol is methyl alcohol. It is interesting to note that wood alcohol is a dangerous poison, whereas the grain alcohol in beer and wine is safe to consume in moderate quantities.

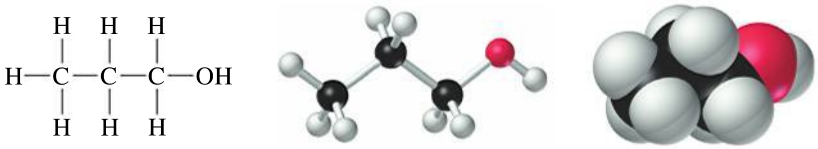
The $-OH$ group in alcohols is one of the many *functional groups* found in organic compounds. **Functional groups** are individual atoms or groupings of



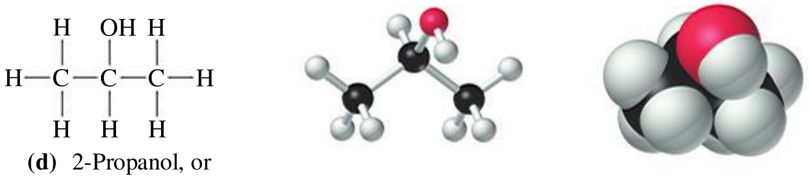
(a) Ethanol, or Ethyl alcohol



(b) Methanol, or Methyl alcohol



(c) 1-Propanol, or Propyl alcohol



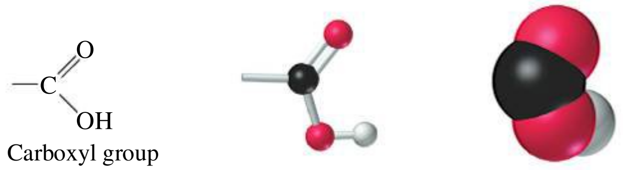
(d) 2-Propanol, or Isopropyl alcohol

◀ FIGURE 3-10
Visualizations of some alcohols

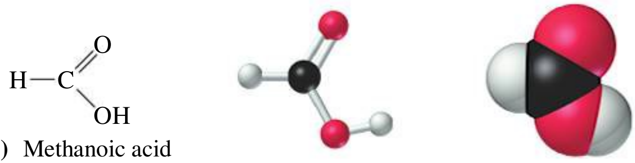
atoms that are attached to the carbon chains or rings of organic molecules and give the molecules their characteristic properties. Compounds with the same functional group generally have similar properties. The —OH group is called the *hydroxyl group*. At this point only a few functional groups will be introduced; functional groups are discussed in more detail in Chapter 26.

The presence of functional groups also increases the possibility of isomers. For example, there is only one propane molecule, C_3H_8. However, if one of the H atoms is replaced by a hydroxyl group, two possibilities exist for the point of attachment: at one of the end C atoms or at the middle C atom (Figs. 3.10c and d). This leads to two isomers. The alcohol with the —OH group attached to the end carbon atom is commonly called propyl alcohol or, systematically, 1-propanol; the prefix 1- indicates that the —OH group is on the first or end C atom. The alcohol with the —OH group attached to the middle carbon atom is commonly called isopropyl alcohol or, systematically, 2-propanol; the prefix 2- indicates that the —OH group is on the second C atom from the end.

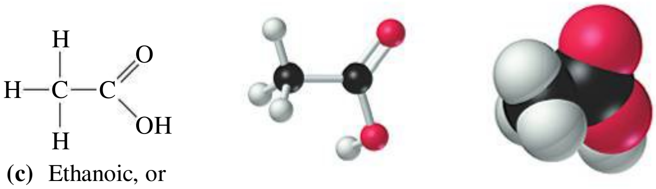
Another important functional group is the *carboxyl* group, —COOH, or —CO_2H which confers acidic properties on a molecule. The C atom in the carboxyl group is bound to the two O atoms in two ways. One bond is a single bond to an oxygen atom that is also attached to a H atom, and the other is a double bond to a lone O atom (Fig. 3-11a). The hydrogen attached to one of the O atoms in a carboxyl group is *ionizable* or *acidic*. Compounds containing the carboxyl group are called **carboxylic acids**. The first carboxylic acid based on alkanes is *methanoic* acid, HCOOH (Fig. 3.11b). In the systematic name, the *methan-* indicates one carbon atom and the *-oic* acid indicates a carboxylic acid. The common name for methanoic acid is formic acid, deriving from the Latin word *formica*, meaning "ant." Formic acid is injected by an ant when it bites; this leads to the burning sensation that accompanies the bite.



(a) Carboxyl group



(b) Methanoic acid



(c) Ethanoic, or Acetic acid

▶ FIGURE 3-11
The carboxyl group and visualizations of two carboxylic acids

The simplest carboxylic acid containing two carbon atoms is *ethanoic* acid, more commonly known as acetic acid. The molecular formula is CH_3COOH, and the structure is shown in Figure 3-11(c). Vinegar is a solution of acetic acid in water. An additional functional group is introduced in the examples that follow—a halogen atom (F, Cl, Br, I) substituting for one or more H atoms. When present as functional groups, the halogens carry the names, *fluoro-*, *chloro-*, *bromo-*, and *iodo-*.

EXAMPLE 3-13 Recognizing Types of Organic Compounds

What type of compound is each of the following?

(a) $CH_3CH_2CH_2CH_3$ **(b)** $CH_3CHClCH_2CH_3$
(c) $CH_3CH_2CO_2H$ **(d)** $CH_3CH_2CH(OH)CH_2CH_3$

Analyze

For each compound, examine the formula to determine which functional group, if any, is present. Also consider whether or not all the carbon–carbon bonds are single bonds.

Solve

(a) The carbon–carbon bonds are all single bonds in this hydrocarbon. This compound is an alkane.

(b) There are only single bonds in its molecules, and one H atom has been replaced by a Cl atom. This compound is a chloroalkane.

(c) The presence of the carboxyl group, $—CO_2H$, in its molecules means that this compound is a carboxylic acid.

(d) The presence of the hydroxyl group, —OH, in its molecules means that this compound is an alcohol.

Assess

Carbon–hydrogen and carbon–carbon bonds, especially carbon–carbon single bonds, are relatively unreactive. Because of this, functional groups are most important in determining the characteristic properties of organic compounds. We will encounter other functional groups and examine organic compounds in more detail in Chapters 26 and 27.

PRACTICE EXAMPLE A: What types of compounds correspond to each of the following formulas?

(a) $CH_3CH_2CH_3$ **(b)** $ClCH_2CH_2CH_3$
(c) $CH_3CH_2CH_2CO_2H$ **(d)** $CH_3CHCHCH_3$

PRACTICE EXAMPLE B: What types of compounds correspond to these formulas?

(a) $CH_3CH(OH)CH_3$ **(b)** $CH_3CH(OH)CH_2CO_2H$
(c) $CH_2ClCH_2CO_2H$ **(d)** $BrCHCHCH_3$

EXAMPLE 3-14 Naming Organic Compounds

Name these compounds.

(a) $CH_3CH_2CH_2CH_2CH_3$ **(b)** $CH_3CHFCH_2CH_3$
(c) $CH_3CH_2CO_2H$ **(d)** $CH_3CH_2CH(OH)CH_2CH_3$

Analyze

First, determine the type of compound. Then, count the number of carbon atoms and select the appropriate stem (or prefix) from Table 3.7 to form the name. If the compound is an alcohol, change the final *-e* in the name to *-ol*; if it is a carboxylic acid, change the final *-e* to *-oic acid*.

Solve

(a) The structure is that of an alkane molecule with a five-carbon chain, so the compound is pentane.

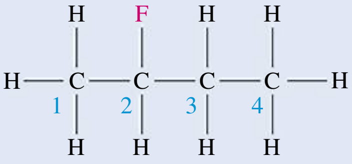
(b) The structure is that of a fluoroalkane molecule with the F atom on the *second* C atom of a four-carbon chain. The compound is called 2-fluorobutane.

(c) The carbon chain in this structure is three C atoms long, with the end C atom in a carboxyl group. The compound is propanoic acid.

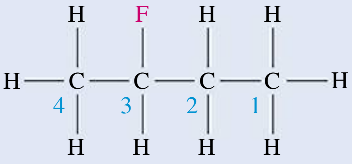
(d) This structure is that of an alcohol with the hydroxyl group on the *third* C atom of a five-carbon chain. The compound is called 3-pentanol.

Assess

In naming the compound in part **(b)**, we stated that the F atom was bonded to the second C atom in a four-carbon chain. There is some ambiguity in that statement because, as illustrated below, we can number the C atoms in two different ways.



2-fluorobutane
(correct)



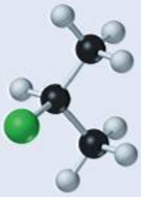
3-fluorobutane
(incorrect)

By convention, we always number the carbon atoms so that the position of the functional group is designated by the smallest possible number. Thus, 2-fluorobutane is the correct name.

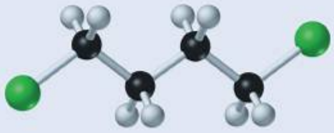
PRACTICE EXAMPLE A: Name the following compounds: **(a)** $CH_3CH(OH)CH_3$; **(b)** $ICH_2CH_2CH_3$; **(c)** $CH_3CH(CH_3)CH_2CO_2H$; **(d)** CH_3CHCH_2.

PRACTICE EXAMPLE B: Give plausible names for the molecules that correspond to the following ball-and-stick models.

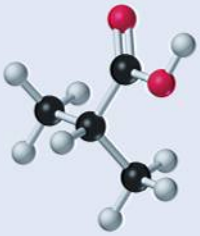
(a)



(b)



(c)



EXAMPLE 3-15 Writing Structural Formulas from the Names of Organic Compounds

Write the condensed structural formula for the organic compounds: **(a)** butane, **(b)** butanoic acid, **(c)** 1-chloropentane, **(d)** 1-hexanol.

Analyze

First, identify the number of carbon atoms in the chain, and then determine the type and position of the functional group, if any.

Solve

(a) The word stem *but-* indicates a structure with a four-carbon chain, and the suffix *-ane* indicates an alkane. No functional groups are indicated; hence, the condensed structural formula is $CH_3(CH_2)_2CH_3$.

(b) The *-oic* ending indicates that the end carbon atom of the four-carbon chain is part of a carboxylic acid group. The condensed structural formula is $CH_3(CH_2)_2CO_2H$.

(c) The prefix *chloro-* indicates the substitution of a chlorine atom for a H atom, and the 1- designates that it is on the first C atom of the carbon chain. The carbon chain is five C atoms long, as signified by the word stem *pent-*. The condensed structural formula is $CH_3(CH_2)_3CH_2Cl$.

(d) The suffix *-ol* indicates the presence of a hydroxyl group in place of a H atom, and the 1- designates that it is on the first C atom of the carbon chain. The word stem *hex-* signifies that the carbon chain is six C atoms long. The condensed structural formula is $CH_3(CH_2)_4CH_2OH$.

Assess

In summary, to obtain a structural formula from the name, we split the name into its component pieces: stem, prefix, and suffix. All three components provide information about the structure of the molecule.

PRACTICE EXAMPLE A: Write the condensed structural formula for the organic compounds **(a)** pentane, **(b)** ethanoic acid, **(c)** 1-iodooctane (pronounced eye-oh-dough-octane), **(d)** 1-pentanol.

PRACTICE EXAMPLE B: Write the line-angle formula for the organic compounds **(a)** propene, **(b)** 1-heptanol, **(c)** chloroacetic acid, **(d)** hexanoic acid.

MasteringCHEMISTRY **www.masteringchemistry.com.**

For a discussion of how chemists use mass spectrometry to establish both molecular and structural formulas, go to the Focus On feature for Chapter 3, entitled Mass Spectrometry—Determining Molecular and Structural Formulas, on the MasteringChemistry site.

Summary

3-1 Types of Chemical Compounds and Their Formulas—The two main classes of chemical compounds are **molecular compounds** and **ionic compounds**. The fundamental unit of a molecular compound is a molecule and that of an ionic compound is a **formula unit**. A formula unit is the smallest collection of positively charged ions—called **cations**—and negatively charged ions—called **anions**—that is electrically neutral overall. A **chemical formula** is a symbolic representation of a compound that can be written in several ways (Fig. 3-1). If the formula has the smallest integral subscripts possible, it is an **empirical formula**; if the formula represents an actual molecule, it is a **molecular formula**; and if the formula is written to show how individual atoms are joined together into molecules, it is a **structural formula**. Abbreviated structural formulas, called **condensed structural formulas**, are often used for organic molecules. Also used for organic molecules is the **line-angle formula**, in which all bond lines are shown except those between C and H atoms and in which the symbols C and H are mostly omitted. The relative sizes and positions of the atoms in molecules can be depicted by ball-and-stick and space-filling molecular models.

3-2 The Mole Concept and Chemical Compounds—In this section, the concept of atomic mass is extended to **molecular mass**, the mass in atomic mass units of a molecule of a molecular compound, and **formula mass**, the mass in atomic mass units of a formula unit of an ionic compound. Likewise, the concept of the Avogadro constant and the mole is now applied to compounds, with emphasis on quantitative applications involving the mass of a mole of compound—the **molar mass** *M*. For several elements, we can distinguish between a mole of molecules (for example, P_4) and a mole of atoms (that is, P).

3-3 Composition of Chemical Compounds—The mass percent composition of a compound can be established from its formula (equation 3.1). Conversely, a chemical formula can be deduced from the experimentally determined percent composition of the compound. For organic compounds, this often involves combustion analysis (Fig. 3-6). Formulas determined from experimental percent composition data are empirical formulas—the simplest formulas that can be written. Molecular formulas can be related to empirical formulas when experimentally determined molecular masses are available.

3-4 Oxidation States: A Useful Tool in Describing Chemical Compounds—The **oxidation state** of an atom is roughly related to the number of electrons involved in the formation of a bond between that atom and another atom. Oxidation states are expressed as numbers assigned according to a set of conventions (Table 3.2). The oxidation state concept has several uses, one of which is to aid in naming chemical compounds and in writing chemical formulas.

3-5 Naming Compounds: Organic and Inorganic Compounds—**Assigning names** to the formulas of chemical compounds—nomenclature—is an important activity in chemistry. The topic is introduced in this section and applied to two broad categories: (1) **organic compounds**, which are compounds formed by the elements carbon and hydrogen, often together with a few other elements, such as oxygen and nitrogen; and (2) **inorganic compounds**, a category that includes the remaining chemical compounds. The subject of nomenclature is extended to additional contexts throughout the text.

3-6 Names and Formulas of Inorganic Compounds—In this section on the nomenclature of inorganic compounds, the names and formulas of two-element or **binary compounds** are considered first. The names and symbols of some simple ions (Table 3.3) and the names of a few typical binary molecular compounds (Table 3.4) are listed. Also listed are some common ions comprising two or more atoms, **polyatomic ions**, and typical ionic compounds containing them (Table 3.5). The naming of binary acids is related to the names of the corresponding binary hydrogen compounds. The majority of acids, however, are **ternary compounds**; they consist of three elements—hydrogen and two other nonmetals. Typically, one of the elements in ternary acids is oxygen, giving rise to the name **oxoacids**. The polyatomic anions derived from oxoacids are **oxoanions**. A scheme for relating the names and formulas of oxoanions is given (expression 3.3), and the nomenclature of oxoacids and their salts is summarized (Table 3.6). Also described in this section are **hydrates**, ionic compounds having fixed numbers of water molecules associated with their formula units.

3-7 Names and Formulas of Organic Compounds—Organic compounds are based on the element carbon. **Hydrocarbons** contain only carbon and hydrogen (Fig. 3-9). **Alkane** hydrocarbon molecules contain only single bonds, and alkenes contain at least one double bond. A common phenomenon found in organic compounds is isomerism—the existence of different compounds, called **isomers**, having identical molecular formulas but different structural formulas. **Functional groups** confer distinctive properties on organic molecules when they are substituted for H atoms on carbon chains or rings. The hydroxyl group —OH is present in **alcohols** (Fig. 3-10) and the carboxyl group —COOH, in **carboxylic acids** (Fig. 3-11).

Integrative Example

Molecules of a dicarboxylic acid have *two* carboxyl groups (—COOH). A 2.250 g sample of a dicarboxylic acid was burned in an excess of oxygen and yielded 4.548 g CO_2 and 1.629 g H_2O. In a separate experiment, the molecular mass of the acid was found to be 174 u. From these data, what can we deduce about the structural formula of this acid?

Analyze

Our approach will require several steps: (1) Use the combustion data to determine the percent composition of the compound (similar to Example 3-6). (2) Determine the empirical formula from the percent composition (similar to Example 3-5). (3) Obtain the molecular formula from the empirical formula and the molecular mass. (4) Determine how the C, H, and O atoms represented in the molecular formula might be assembled into a dicarboxylic acid. Use molar masses with (at least) one more significant figure than in the measured masses; store intermediate results in your calculator without rounding off.

Solve

1. *Determine the percent composition.* Calculate the mass of H in 1.629 g H_2O

$$? \text{ g H} = 1.629 \text{ g H}_2\text{O} \times \frac{1 \text{ mol H}_2\text{O}}{18.015 \text{ g H}_2\text{O}} \times \frac{2 \text{ mol H}}{1 \text{ mol H}_2\text{O}} \times \frac{1.0079 \text{ g H}}{1 \text{ mol H}} = 0.1823 \text{ g H}$$

and then the mass percent H in the 2.250 g sample of the dicarboxylic acid.

$$\% \text{ H} = \frac{0.1823 \text{ g H}}{2.250 \text{ g compd.}} \times 100\% = 8.102\% \text{ H}$$

Also, calculate the mass of C in 4.548 g CO_2,

$$? \text{ g C} = 4.548 \text{ g CO}_2 \times \frac{1 \text{ mol CO}_2}{44.010 \text{ g CO}_2} \times \frac{1 \text{ mol C}}{1 \text{ mol CO}_2} \times \frac{12.011 \text{ g C}}{1 \text{ mol C}} = 1.241 \text{ g C}$$

followed by the mass percent C in the 2.250 g sample of dicarboxylic acid.

$$\% \text{ C} = \frac{1.241 \text{ g C}}{2.250 \text{ g compd.}} \times 100\% = 55.16\% \text{ C}$$

The % O in the compound is obtained as a difference, that is,

$$\% \text{ O} = 100.00\% - 55.16\% \text{ C} - 8.102\% \text{ H} = 36.74\ \% \text{ O}$$

2. *Obtain the empirical formula from the percent composition.* The masses of the elements in 100.0 g of the compound are

$$55.16 \text{ g C} \quad 8.102 \text{ g H} \quad 36.74 \text{ g O}$$

The numbers of moles of the elements in 100.0 g of the compound are

$$55.16 \text{ g C} \times \frac{1 \text{ mol C}}{12.011 \text{ g C}} = 4.592 \text{ mol C}$$

$$8.102 \text{ g H} \times \frac{1 \text{ mol H}}{1.0079 \text{ g H}} = 8.038 \text{ mol H}$$

$$36.74 \text{ g O} \times \frac{1 \text{ mol O}}{15.999 \text{ g O}} = 2.296 \text{ mol O}$$

The tentative formula based on these numbers is

$$C_{4.592}H_{8.038}O_{2.296}$$

Divide all the subscripts by 2.296 to obtain

$$C_2H_{3.50}O$$

Multiply all subscripts by two to obtain the empirical formula,

$$C_4H_7O_2$$

and then determine the empirical formula mass.

$$(4 \times 12.0107 \text{ u}) + (7 \times 1.00794 \text{ u}) + (2 \times 15.9994 \text{ u}) = 87.0972 \text{ u}$$

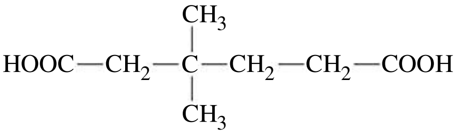
3. *Obtain the molecular formula.* The experimentally determined molecular mass of 174 u is twice the empirical formula mass. The molecular formula is

$$C_8H_{14}O_4$$

4. *Assemble the atoms in* $C_8H_{14}O_4$ *into a plausible structural formula.* The dicarboxylic acid must contain two —COOH groups. This accounts for the two C atoms, two H atoms, and all four O atoms. The remainder of the structure is based on C_6H_{12}. For example, arrange the six —CH_2 segments into a six-carbon chain and attach the —COOH groups at the ends of the chain.

$$HOOC—CH_2(CH_2)_4CH_2—COOH$$

However, there are other possibilities based on shorter chains with branches, for example



$$HOOC—CH_2—\underset{\displaystyle CH_3}{\overset{\displaystyle CH_3}{C}}—CH_2—CH_2—COOH$$

Assess

We have found a plausible structural formula, but there are many other possibilities. For example, the following three isomers have a seven-carbon chain with one methyl group (—CH_3) substituted for an H atom on the chain:

$$HOOCCHCH_3(CH_2)_4COOH; \quad HOOCCH_2CHCH_3(CH_2)_3COOH; \quad HOOC(CH_2)_2CHCH_3(CH_2)_2COOH$$

In conclusion, we cannot identify a specific isomer with only the data given.

PRACTICE EXAMPLE A: A 2.4917 g sample of an unknown solid hydrate was heated to drive off all the water of hydration. The remaining solid, which weighed 1.8558 g, was analyzed and found to be 27.74% Mg, 23.57% P, and 48.69% O, by mass. What is the formula and name of the unknown solid hydrate?

PRACTICE EXAMPLE B: An unknown solid hydrate was analyzed and found to be 17.15% Cu, 19.14% Cl, and 60.45% O, by mass; the remainder was hydrogen. What are the oxidation states of copper and chlorine in this compound? What is the name of this compound?

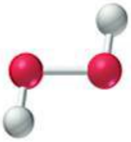
Exercises

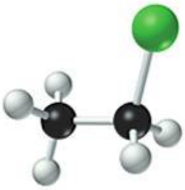
Representing Molecules

1. Refer to the color scheme given in Figure 3-3, and give the molecular formulas for the molecules whose ball-and-stick models are given here.

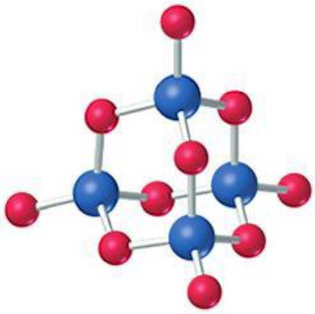
(a)



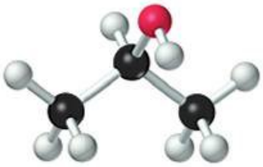
(b)



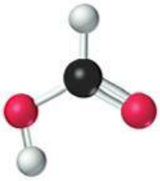
(c)



(d)

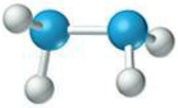


(e)

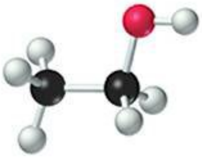


2. Give the molecular formulas for the molecules whose ball-and-stick models are given here. Refer to the color scheme in Figure 3-3.

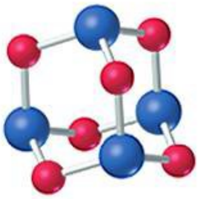
(a)



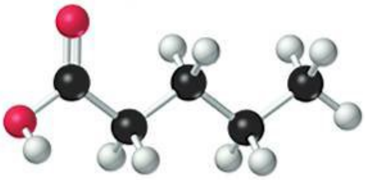
(b)



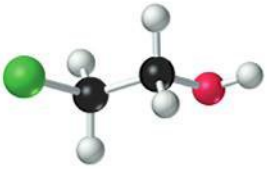
(c)



(d)



(e)



3. Give the structural formulas of the molecules shown in Exercise 1 **(b)**, **(d)**, and **(e)**.
4. Give the structural formulas of the molecules shown in Exercise 2 **(b)**, **(d)**, and **(e)**.

The Avogadro Constant and the Mole

5. Calculate the total number of **(a)** atoms in one molecule of trinitrotoluene (TNT), $CH_3C_6H_2(NO_2)_3$; **(b)** atoms in 0.00102 mol $CH_3(CH_2)_4CH_2OH$; **(c)** F atoms in 12.15 mol $C_2HBrClF_3$.
6. Determine the *mass*, in grams, of
   (a) 7.34 mol N_2O_4;
   (b) 3.16×10^{24} O_2 molecules;
   (c) 18.6 mol $CuSO_4 \cdot 5\,H_2O$;
   (d) 4.18×10^{24} molecules of $C_2H_4(OH)_2$.
7. The amino acid methionine, which is essential in human diets, has the molecular formula $C_5H_{11}NO_2S$. Determine **(a)** its molecular mass; **(b)** the number of moles of H atoms per mole of methionine;

(c) the number of grams of C per mole of methionine; **(d)** the number of C atoms in 9.07 mol methionine.

8. Determine the number of moles of Br_2 in a sample consisting of **(a)** 8.08×10^{22} Br_2 molecules; **(b)** 2.17×10^{24} Br atoms; **(c)** 11.3 kg bromine; **(d)** 2.65 L liquid bromine ($d = 3.10$ g/mL).

9. *Without doing detailed calculations*, explain which of the following has the greatest number of N atoms **(a)** 50.0 g N_2O; **(b)** 17.0 g NH_3; **(c)** 150 mL of liquid pyridine, C_5H_5N ($d = 0.983$ g/mL); **(d)** 1.0 mol N_2.

10. *Without doing detailed calculations*, determine which of the following has the greatest number of S atoms **(a)** 0.12 mol of solid sulfur, S_8; **(b)** 0.50 mol of gaseous S_2O; **(c)** 65 g of gaseous SO_2; **(d)** 75 mL of liquid thiophene, C_4H_4S ($d = 1.064$ g/mL).

11. Determine the number of *moles* of
(a) N_2O_4 in a 115 g sample
(b) N atoms in 43.5 g of $Mg(NO_3)_2$
(c) N atoms in a sample of $C_7H_5(NO_2)_3$ that has the same number of O atoms as 12.4 g $C_6H_{12}O_6$

12. Determine the *mass*, in grams, of
(a) 6.25×10^{-2} mol P_4
(b) 4.03×10^{24} molecules of stearic acid, $C_{18}H_{36}O_2$
(c) a quantity of the amino acid lysine, $C_6H_{14}N_2O_2$, containing 3.03 mol N atoms

13. The hemoglobin content of blood is about 15.5 g/100 mL blood. The molar mass of hemoglobin is about 64,500 g/mol, and there are four iron (Fe) atoms in a hemoglobin molecule. Approximately how many Fe atoms are present in the 6 L of blood in a typical adult?

14. In white phosphorus, P atoms are joined into P_4 molecules (see Figure 3-5). White phosphorus is commonly supplied in chalk-like cylindrical form. Its density is 1.823 g/cm^3. For a cylinder of white phosphorus 6.50 cm long and 1.22 cm in diameter, determine **(a)** the number of moles of P_4 present; **(b)** the total number of P atoms.

Chemical Formulas

15. Explain which of the following statement(s) is (are) correct concerning glucose (blood sugar),$C_6H_{12}O_6$.
(a) The percentages, by mass, of C and O are the same as in CO.
(b) The ratio of C : H : O atoms is the same as in dihydroxyacetone, $(CH_2OH)_2CO$.
(c) The proportions, by mass, of C and O are equal.
(d) The highest percentage, by mass, is that of H.

16. Explain which of the following statement(s) is (are) correct for sorbic acid, $C_6H_8O_2$, an inhibitor of mold and yeast.
(a) It has a C : H : O mass ratio of 3 : 4 : 1.
(b) It has the same mass percent composition as the aquatic herbicide, acrolein, C_3H_4O.
(c) It has the same empirical formula as aspidinol, $C_{12}H_{16}O_4$, a drug used to kill parasitic worms.
(d) It has four times as many H atoms as O atoms, but four times as much O as H by mass.

17. For the mineral torbernite, $Cu(UO_2)_2(PO_4)_2 \cdot 8\,H_2O$, determine
(a) the total number of atoms in one formula unit
(b) the ratio, by number, of H atoms to O atoms
(c) the ratio, by mass, of Cu to P
(d) the element present in the greatest mass percent
(e) the mass required to contain 1.00 g P

18. For the compound $Ge[S(CH_2)_4CH_3]_4$, determine
(a) the total number of atoms in one formula unit
(b) the ratio, by number, of C atoms to H atoms
(c) the ratio, by mass, of Ge to S
(d) the number of g S in 1 mol of the compound
(e) the number of C atoms in 33.10 g of the compound

Percent Composition of Compounds

19. Determine the mass percent H in the hydrocarbon decane, $C_{10}H_{22}$.

20. Determine the mass percent O in the mineral malachite, $Cu_2(OH)_2CO_3$.

21. Determine the mass percent H in the hydrocarbon isooctane, $C(CH_3)_3CH_2CH(CH_3)_2$.

22. Determine the mass percent H_2O in the hydrate $Cr(NO_3)_3 \cdot 9\,H_2O$.

23. Determine the mass percent of each of the elements in the antimalarial drug quinine, $C_{20}H_{24}N_2O_2$.

24. Determine the mass percent of each of the elements in the fungicide copper(II) oleate, $Cu(C_{18}H_{33}O_2)_2$.

25. Determine the percent, by mass, of the indicated element:
(a) Pb in tetraethyl lead, $Pb(C_2H_5)_4$, once extensively used as an additive to gasoline to prevent engine knocking
(b) Fe in Prussian blue, $Fe_4[Fe(CN)_6]_3$, a pigment used in paints and printing inks
(c) Mg in chlorophyll, $C_{55}H_{72}MgN_4O_5$, the green pigment in plant cells

26. All of the following minerals are semiprecious or precious stones. Determine the mass percent of the indicated element.
(a) Zr in zircon, $ZrSiO_4$
(b) Be in beryl (emerald), $Be_3Al_2Si_6O_{18}$
(c) Fe in almandine (garnet), $Fe_3Al_2Si_3O_{12}$
(d) S in lazurite (lapis lazuli), $Na_4SSi_3Al_3O_{12}$

27. *Without doing detailed calculations*, arrange the following in order of increasing % Cr, by mass, and explain your reasoning: CrO, Cr_2O_3, CrO_2, CrO_3.

28. Without doing detailed calculations, explain which of the following has the greatest mass percent of sulfur: SO_2, S_2Cl_2, Na_2S, $Na_2S_2O_3$, or CH_3CH_2SH.

Chemical Formulas from Percent Composition

29. Two oxides of sulfur have nearly identical molecular masses. One oxide consists of 40.05% S. What are the simplest possible formulas for the two oxides?

30. An oxide of chromium used in chrome plating has a formula mass of 100.0 u and contains *four* atoms per formula unit. Establish the formula of this compound, *with a minimum of calculation*.

31. Diethylene glycol, used to deice aircraft, is a carbon–hydrogen–oxygen compound with 45.27% C and 9.50% H by mass. What is its empirical formula?

32. The food flavor enhancer monosodium glutamate (MSG) has the composition 13.6% Na, 35.5% C, 4.8% H, 8.3% N, 37.8% O, by mass. What is the empirical formula of MSG?

33. Determine the empirical formula of **(a)** the rodenticide (rat killer) warfarin, which consists of 74.01% C, 5.23% H, and 20.76% O, by mass; **(b)** the antibacterial agent sulfamethizole, which consists of 39.98% C, 3.73% H, 20.73% N, 11.84% O, and 23.72% S, by mass.

34. Determine the empirical formula of **(a)** benzo-[*a*]pyrene, a suspected carcinogen found in cigarette smoke, consisting of 95.21% C and 4.79% H, by mass; **(b)** hexachlorophene, used in germicidal soaps, which consists of 38.37% C, 1.49% H, 52.28% Cl, and 7.86% O by mass.

35. A compound of carbon and hydrogen consists of 94.34% C and 5.66% H, by mass. The molecular mass of the compound is found to be 178 u. What is its molecular formula?

36. Selenium, an element used in the manufacture of photoelectric cells and solar energy devices, forms two oxides. One has 28.8% O, by mass, and the other, 37.8% O. What are the formulas of these oxides? Propose acceptable names for them.

37. Indigo, the dye for blue jeans, has a percent composition, by mass, of 73.27% C, 3.84% H, 10.68% N, and the remainder is oxygen. The molecular mass of indigo is 262.3 u. What is the molecular formula of indigo?

38. Adenine, a component of nucleic acids, has the mass percent composition: 44.45% C, 3.73% H, 51.82% N. Its molecular mass is 135.14 u. What is its molecular formula?

39. The element X forms the chloride XCl_4 containing 75.0% Cl, by mass. What is element X?

40. The element X forms the compound $XOCl_2$ containing 59.6% Cl. What is element X?

41. Chlorophyll contains 2.72% Mg by mass. Assuming one Mg atom per chlorophyll molecule, what is the molecular mass of chlorophyll?

42. Two compounds of Cl and X are found to have molecular masses and % Cl, by mass, as follows: 137 u, 77.5% Cl; 208 u, 85.1% Cl. What is element X? What is the formula for each compound?

Combustion Analysis

43. A 0.1888 g sample of a hydrocarbon produces 0.6260 g CO_2 and 0.1602 g H_2O in combustion analysis. Its molecular mass is found to be 106 u. For this hydrocarbon, determine its **(a)** mass percent composition; **(b)** empirical formula; **(c)** molecular formula.

44. *Para*-cresol (*p*-cresol) is used as a disinfectant and in the manufacture of herbicides. A 0.4039 g sample of this carbon–hydrogen–oxygen compound yields 1.1518 g CO_2 and 0.2694 g H_2O in combustion analysis. Its molecular mass is 108.1 u. For *p*-cresol, determine its **(a)** mass percent composition; **(b)** empirical formula; **(c)** molecular formula.

45. Dimethylhydrazine is a carbon–hydrogen–nitrogen compound used in rocket fuels. When burned in an excess of oxygen, a 0.312 g sample yields 0.458 g CO_2 and 0.374 g H_2O. The nitrogen content of a 0.486 g sample is converted to 0.226 g N_2. What is the empirical formula of dimethylhydrazine?

46. The organic solvent thiophene is a carbon–hydrogen–sulfur compound that yields CO_2, H_2O, and SO_2 when burned in an excess of oxygen. When subjected to combustion analysis, a 1.3020 g sample of thiophene produces 2.7224 g CO_2, 0.5575 g H_2O, and 0.9915 g SO_2. What is the empirical formula of thiophene?

47. *Without doing detailed calculations*, explain which of these compounds produces the *greatest* mass of CO_2 when 1.00 mol of the compound is burned in an excess of oxygen: CH_4, C_2H_5OH, $C_{10}H_8$, C_6H_5OH.

48. *Without doing detailed calculations*, explain which of these compounds produces the *greatest* mass of H_2O when 1.00 g of the compound is burned in an excess of oxygen: CH_4, C_2H_5OH, $C_{10}H_8$, C_6H_5OH.

49. A 1.562 g sample of the alcohol $CH_3CHOHCH_2CH_3$ is burned in an excess of oxygen. What masses of CO_2 and H_2O should be obtained?

50. Liquid ethyl mercaptan, C_2H_6S, has a density of 0.84 g/mL. Assuming that the combustion of this compound produces only CO_2, H_2O, and SO_2, what masses of each of these three products would be produced in the combustion of 3.15 mL of ethyl mercaptan?

Oxidation States

51. Indicate the oxidation state of the underlined element in **(a)** $\underline{C}H_4$; **(b)** $\underline{S}F_4$; **(c)** $Na_2\underline{O}_2$; **(d)** $\underline{C}_2H_3O_2^-$; **(e)** $\underline{Fe}O_4^{2-}$.

52. Indicate the oxidation state of S in **(a)** SO_3^{2-}; **(b)** $S_2O_3^{2-}$; **(c)** $S_2O_8^{2-}$; **(d)** HSO_4^-; **(e)** $S_4O_6^{2-}$.

53. Chromium forms three principal oxides. Write appropriate formulas for these compounds in which the oxidation states of Cr are +3, +4, and +6, respectively.

54. Nitrogen forms five oxides in which its oxidation states are +1, +2, +3, +4, and +5, respectively. Write appropriate formulas for these compounds.

55. In many of its compounds, oxygen has an oxidation state of −2. However, there are exceptions. What is the oxidation state of oxygen in each of the following compounds? **(a)** OF_2; **(b)** O_2F_2; **(c)** CsO_2; **(d)** BaO_2.

56. Hydrogen and oxygen usually have oxidation states of +1 and −2, respectively, in their compounds. The following cases serve to remind us that there are exceptions. What are the oxidation states of the atoms in each of the following compounds? **(a)** MgH_2; **(b)** CsO_3; **(c)** HOF; **(d)** $NaAlH_4$.

Nomenclature

57. Name these compounds: **(a)** SrO; **(b)** ZnS; **(c)** K_2CrO_4; **(d)** Cs_2SO_4; **(e)** Cr_2O_3; **(f)** $Fe_2(SO_4)_3$; **(g)** $Mg(HCO_3)_2$; **(h)** $(NH_4)_2HPO_4$; **(i)** $Ca(HSO_3)_2$; **(j)** $Cu(OH)_2$; **(k)** HNO_3; **(l)** $KClO_4$; **(m)** $HBrO_3$; **(n)** H_3PO_3.

58. Name these compounds: **(a)** $Ba(NO_3)_2$; **(b)** HNO_2; **(c)** CrO_2; **(d)** KIO_3; **(e)** LiCN; **(f)** KIO; **(g)** $Fe(OH)_2$; **(h)** $Ca(H_2PO_4)_2$; **(i)** H_3PO_4; **(j)** $NaHSO_4$; **(k)** $Na_2Cr_2O_7$; **(l)** $NH_4C_2H_3O_2$; **(m)** MgC_2O_4; **(n)** $Na_2C_2O_4$.

59. Assign suitable names to the compounds **(a)** CS_2; **(b)** SiF_4; **(c)** ClF_5; **(d)** N_2O_5; **(e)** SF_6; **(f)** I_2Cl_6.

60. Assign suitable names to the compounds **(a)** ICl; **(b)** ClF_3; **(c)** SF_4; **(d)** BrF_5; **(e)** N_2O_4; **(f)** S_4N_4.

61. Write formulas for the compounds: **(a)** aluminum sulfate; **(b)** ammonium dichromate; **(c)** silicon tetrafluoride; **(d)** iron(III) oxide; **(e)** tricarbon disulfide; **(f)** cobalt(II) nitrate; **(g)** strontium nitrite; **(h)** hydrobromic acid; **(i)** iodic acid; **(j)** phosphorus dichloride trifluoride.

62. Write formulas for the compounds: **(a)** magnesium perchlorate; **(b)** lead(II) acetate; **(c)** tin(IV) oxide; **(d)** hydroiodic acid; **(e)** chlorous acid; **(f)** sodium hydrogen sulfite; **(g)** calcium dihydrogen phosphate; **(h)** aluminum phosphate; **(i)** dinitrogen tetroxide; **(j)** disulfur dichloride.

63. Write a formula for **(a)** the chloride of titanium having Ti in the O.S. +4; **(b)** the sulfate of iron having Fe in the O.S. +3; **(c)** an oxide of chlorine with Cl in the O.S. +7; **(d)** an oxoanion of sulfur in which the apparent O.S. of S is +7 and the ionic charge is 2−.

64. Write a formula for **(a)** an oxide of nitrogen with N in the O.S. +5; **(b)** an oxoacid of nitrogen with N in the O.S. +3; **(c)** an oxide of carbon in which the apparent O.S. of C is +4/3; **(d)** a sulfur-containing oxoanion in which the apparent O.S. of S is +2.5 and the ionic charge is 2−.

65. Name the acids: **(a)** $HClO_2$; **(b)** H_2SO_3; **(c)** H_2Se; **(d)** HNO_2.

66. Supply the formula for the acids: **(a)** hydrofluoric acid; **(b)** nitric acid; **(c)** phosphorous acid; **(d)** sulfuric acid.

67. Name the following compounds and specify which ones are best described as ionic: **(a)** OF_2; **(b)** XeF_2; **(c)** $CuSO_3$; **(d)** $(NH_4)_2HPO_4$;.

68. Name the following compounds and specify which ones are best described as ionic: **(a)** KNO_2; **(b)** BrF_3; **(c)** S_2Cl_2; **(d)** $Mg(ClO)_2$; **(e)** Cl_2O.

Hydrates

69. *Without performing detailed calculations*, indicate which of the following hydrates has the greatest % H_2O by mass: $CuSO_4 \cdot 5\,H_2O$, $Cr_2(SO_4)_3 \cdot 18\,H_2O$, $MgCl_2 \cdot 6\,H_2O$, and $LiC_2H_3O_2 \cdot 2\,H_2O$.

70. *Without performing detailed calculations*, determine the hydrate of Na_2SO_3 that contains almost exactly 50% H_2O, by mass.

71. Anhydrous $CuSO_4$ can be used to dry liquids in which it is insoluble. The $CuSO_4$ is converted to $CuSO_4 \cdot 5\,H_2O$, which can be filtered off from the liquid. What is the minimum mass of anhydrous $CuSO_4$ needed to remove 12.6 g H_2O from a tankful of gasoline?

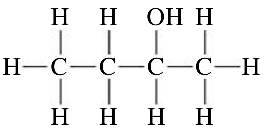
72. Anhydrous sodium sulfate, Na_2SO_4, absorbs water vapor and is converted to the decahydrate, $Na_2SO_4 \cdot 10\,H_2O$. How much would the mass of 24.05 g of anhydrous Na_2SO_4 increase if converted completely to the decahydrate?

73. A certain hydrate is found to have the composition 20.3% Cu, 8.95% Si, 36.3% F, and 34.5% H_2O by mass. What is the empirical formula of this hydrate?

74. An 8.129 g sample of $MgSO_4 \cdot x\,H_2O$ is heated until all the water of hydration is driven off. The resulting anhydrous compound, $MgSO_4$, weighs 3.967 g. What is the formula of the hydrate?

Organic Compounds and Organic Nomenclature

75. Which of the following names is most appropriate for the molecule with the structure shown below? **(a)** butyl alcohol; **(b)** 2-butanol; **(c)** 1-butanol; **(d)** isopentyl alcohol.

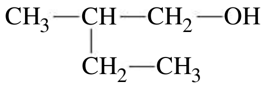


$$\begin{array}{ccccccccccc} & & H & & H & & OH & & H & & \\ & & | & & | & & | & & | & & \\ H & - & C & - & C & - & C & - & C & - & H \\ & & | & & | & & | & & | & & \\ & & H & & H & & H & & H & & \end{array}$$

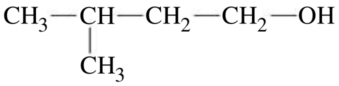
76. Which of the following names is most appropriate for the molecule $CH_3(CH_2)_2COOH$? **(a)** dimethyleneacetic acid; **(b)** propanoic acid; **(c)** butanoic acid; **(d)** oxobutylalcohol.

77. Which of the following structures are isomers?

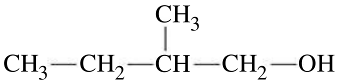
(a)



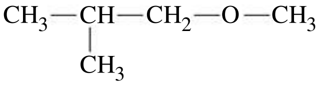
$$\begin{array}{lllll} CH_3 & - & CH & - & CH_2-OH \\ & & | & & \\ & & CH_2-CH_3 & & \end{array}$$

(b)


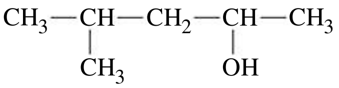
$\mathrm{CH_3-\underset{\substack{|\\ CH_3}}{CH}-CH_2-CH_2-OH}$

(c)


$\mathrm{CH_3-CH_2-\overset{\substack{CH_3\\ |}}{CH}-CH_2-OH}$

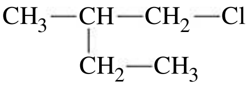
(d)


$\mathrm{CH_3-\underset{\substack{|\\ CH_3}}{CH}-CH_2-O-CH_3}$

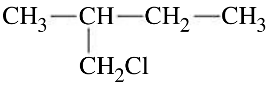
(e)


$\mathrm{CH_3-\underset{\substack{|\\ CH_3}}{CH}-CH_2-\underset{\substack{|\\ OH}}{CH}-CH_3}$

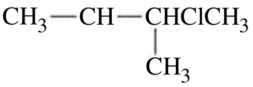
78. Which of the following structures are isomers?

(a)


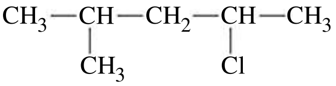
$\mathrm{CH_3-\underset{\substack{|\\ CH_2-CH_3}}{CH}-CH_2-Cl}$

(b)


$\mathrm{CH_3-\underset{\substack{|\\ CH_2Cl}}{CH}-CH_2-CH_3}$

(c)


$\mathrm{CH_3-CH-\underset{\substack{|\\ CH_3}}{C}HClCH_3}$

(d)


$\mathrm{CH_3-\underset{\substack{|\\ CH_3}}{CH}-CH_2-\underset{\substack{|\\ Cl}}{CH}-CH_3}$

79. Write the condensed structural formulas for the organic compounds:

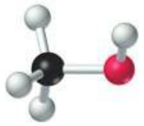
(a) heptane **(b)** propanoic acid
(c) 2-methyl-1-pentanol **(d)** fluoroethane

80. Write the condensed structural formulas for the organic compounds:

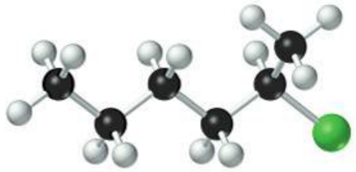
(a) octane **(b)** heptanoic acid
(c) 3-hexanol **(d)** 2-chlorobutane

81. Give the name, condensed structural formula, and molecular mass of the molecule whose ball-and-stick model is shown. Refer to the color scheme in Figure 3-3.

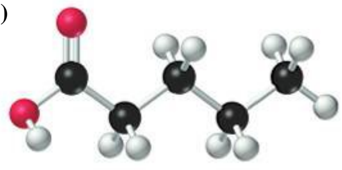
(a)



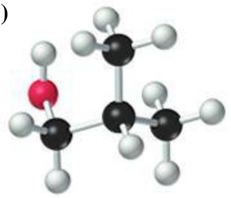
(b)



(c)



(d)



82. Give the name, condensed structural formula, and molecular mass of the molecule whose ball-and-stick model is shown. Refer to the color scheme in Figure 3-3.

Integrative and Advanced Exercises

83. The mineral spodumene has the empirical formula $LiAlSi_2O_6$. Given that the percentage of lithium-6 atoms in naturally occuring lithium is 7.40%, how many lithium-6 atoms are present in a 518 g sample of spodumene?

84. A particular type of brass contains Cu, Sn, Pb, and Zn. A 1.1713 g sample is treated in such a way as to convert the Sn to 0.245 g SnO_2, the Pb to 0.115 g $PbSO_4$, and the Zn to 0.246 g $Zn_2P_2O_7$. What is the mass percent of each element in the sample?

85. A brand of lunchmeat contains 0.10% by mass of sodium benzoate, C_6H_5COONa. How many mg of Na does a person ingest by eating 2.52 oz of this meat?

86. The important natural sources of boron compounds are the minerals kernite, $Na_2B_4O_7 \cdot 4\,H_2O$ and borax, $Na_2B_4O_7 \cdot 10\,H_2O$. How much *additional* mass of mineral must be processed per kilogram of boron obtained if the mineral is borax rather than kernite?

87. To deposit exactly one mole of Ag from an aqueous solution containing Ag^+ requires a quantity of electricity known as one faraday (F). The electrodeposition requires that each Ag^+ ion gain one electron to become an Ag atom. Use appropriate physical constants listed on the inside back cover to obtain a precise value of the Avogadro constant, N_A.

88. By analysis, a compound was found to contain 26.58 % K and 35.45 % Cr by mass; the remainder was oxygen. What is the oxidation state of chromium in this compound? What is the name of the compound?

89. Is it possible to have a sample of S_8 that weighs 1.00×10^{-23} g? What is the smallest possible mass that a sample of S_8 can have? Express your answer to the second question in appropriate SI units so that your answer has a numerical value greater than 1. (See Table 1.2 for a list of SI prefixes.)

90. What is the molecular formula of a hydrocarbon containing *n* carbon atoms and only one double bond? Can such a hydrocarbon yield a greater mass of H_2O than CO_2 when burned in an excess of oxygen?

91. A hydrocarbon mixture consists of 60.0% by mass of C_3H_8 and 40.0% of C_xH_y. When 10.0 g of this mixture is burned, 29.0 g CO_2 and 18.8 g H_2O are the only products. What is the formula of the unknown hydrocarbon?

92. A 0.732 g mixture of methane, CH_4, and ethane, C_2H_6, is burned, yielding 2.064 g CO_2. What is the percent composition of this mixture **(a)** by mass; **(b)** on a mole basis?

93. The density of a mixture of H_2SO_4 and water is 1.78 g/mL. The percent composition of the mixture is to be determined by converting H_2SO_4 to $(NH_4)_2SO_4$. If 32.0 mL of the mixture gives 65.2 g $(NH_4)_2SO_4$, then what is the percent composition of the mixture?

94. All the silver in a 26.39 g sample of impure silver is converted to silver chloride. If 31.56 g of silver chloride are obtained, then what is the mass percent of silver in the sample?

95. In the year 2000, the *Guinness Book of World Records* called ethyl mercaptan, C_2H_6S, the smelliest substance known. The average person can detect its presence in air at levels as low as $9 \times 10^{-4}\ \mu\text{mol/m}^3$. Express the limit of detectability of ethyl mercaptan in parts per billion (ppb). (Note: 1 ppb C_2H_6S means there is 1 g C_2H_6S per billion grams of air.) The density of air is approximately 1.2 g/L at room temperature.

96. Dry air is essentially a mixture of the following entities: N_2, O_2, Ar, and CO_2. The composition of dry air, in *mole percent*, is 78.08% N_2, 20.95% O_2, 0.93% Ar, and 0.04% CO_2. **(a)** What is the mass, in grams, of a sample of air that contains exactly one mole of the entities? **(b)** Dry air also contains other entities in much smaller amounts. For example, the mole percent of krypton (Kr) is about 1.14×10^{-4} %. Given that the density of dry air is about 1.2 g/L at room temperature, what mass of krypton could be obtained from exactly one cubic meter of dry air?

97. A public water supply was found to contain 1 part per billion (ppb) by mass of chloroform, $CHCl_3$. **(a)** How many $CHCl_3$ molecules would be present in a 225 mL glass of this water? **(b)** If the $CHCl_3$ in part **(a)** could be isolated, would this quantity be detectable on an ordinary analytical balance that measures mass with a precision of ±0.0001 g?

98. A sample of the compound MSO_4 weighing 0.1131 g reacts with barium chloride and yields 0.2193 g $BaSO_4$. What must be the atomic mass of the metal M? [*Hint:* All the SO_4^{2-} from the MSO_4 appears in the $BaSO_4$.]

99. The metal M forms the sulfate $M_2(SO_4)_3$. A 0.738 g sample of this sulfate is converted to 1.511 g $BaSO_4$. What is the atomic mass of M?
[*Hint:* Refer to Exercise 98.]

100. A 0.622 g sample of a metal oxide with the formula M_2O_3 is converted to 0.685 g of the sulfide, MS. What is the atomic mass of the metal M?

101. $MgCl_2$ often occurs in table salt (NaCl) and is responsible for caking of the salt. A 0.5200 g sample of table salt is found to contain 61.10% Cl, by mass. What is the % $MgCl_2$ in the sample? Why is the precision of this calculation so poor?

102. When 2.750 g of the oxide of lead Pb_3O_4 is strongly heated, it decomposes and produces 0.0640 g of oxygen gas and 2.686 g of a second oxide of lead. What is the empirical formula of this second oxide?

103. A 1.013 g sample of $ZnSO_4 \cdot x\,H_2O$ is dissolved in water and the sulfate ion precipitated as $BaSO_4$. The mass of pure, dry $BaSO_4$ obtained is 0.8223 g. What is the formula of the zinc sulfate hydrate?

104. The iodide ion in a 1.552 g sample of the ionic compound MI is removed through precipitation. The precipitate is found to contain 1.186 g I. What is the element M?

105. An oxoacid with the formula $H_xE_yO_z$ has a formula mass of 178 u, has 13 atoms in its formula unit, contains 34.80% by mass, and 15.38% by number of atoms, of the element E. What is the element E, and what is the formula of this oxoacid?

106. The insecticide dieldrin contains carbon, hydrogen, oxygen, and chlorine. When burned in an excess of oxygen, a 1.510 g sample yields 2.094 g CO_2 and 0.286 g H_2O. The compound has a molecular mass of 381 u and has half as many chlorine atoms as carbon atoms. What is the molecular formula of dieldrin?

107. A thoroughly dried 1.271 g sample of Na_2SO_4 is exposed to the atmosphere and found to gain 0.387 g in mass. What is the percent, by mass, of $Na_2SO_4 \cdot 10\,H_2O$ in the resulting mixture of anhydrous Na_2SO_4 and the decahydrate?

108. The atomic mass of Bi is to be determined by converting the compound $Bi(C_6H_5)_3$ to Bi_2O_3. If 5.610 g of $Bi(C_6H_5)_3$ yields 2.969 g Bi_2O_3, what is the atomic mass of Bi?

109. A piece of gold (Au) foil measuring 0.25 mm × 15 mm × 15 mm is treated with fluorine gas. The treatment converts all the gold in the foil to 1.400 g of a gold fluoride. What is the formula and name of the fluoride? The density of gold is $19.3\ \text{g/cm}^3$.

110. In an experiment, 244 mL of chlorine gas (Cl_2, $d = 2.898$ g/L) combines with iodine to give 1.553 g of a binary compound. In a separate experiment, the molar mass of the compound is found to be about 467 g/mol. What is the molecular formula of this compound?

Feature Problems

111. All-purpose fertilizers contain the essential elements nitrogen, phosphorus, and potassium. A typical fertilizer carries numbers on its label, such as "5-10-5". These numbers represent the % N, % P_2O_5, and % K_2O, respectively. The N is contained in the form of a nitrogen compound, such as $(NH_4)_2SO_4$, NH_4NO_3, or $CO(NH_2)_2$ (urea). The P is generally present as a phosphate, and the K as KCl. The expressions

% P_2O_5 and % K_2O were devised in the nineteenth century, before the nature of chemical compounds was fully understood. To convert from % P_2O_5 to % P and from % K_2O to % K, the factors 2 mol P/mol P_2O_5 and 2 mol K/mol K_2O must be used, together with molar masses.

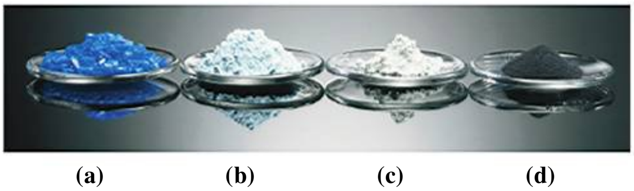
(a) Assuming three-significant-figure precision, what is the percent composition of the "5-10-5" fertilizer in % N, % P, and % K?

(b) What is the % P_2O_5 in the following compounds (both common fertilizers)? **(i)** $Ca(H_2PO_4)_2$; **(ii)** $(NH_4)_2HPO_4$.

(c) In a similar manner to the "5-10-5" fertilizer described in this exercise, how would you describe a fertilizer in which the mass ratio of $(NH_4)_2HPO_4$ to KCl is 5.00:1.00?

(d) Can a "5-10-5" fertilizer be prepared in which $(NH_4)_2HPO_4$ and KCl are the sole fertilizer components, with or without inert nonfertilizer additives? If so, what should be the proportions of the constituents of the fertilizer mixture? If this "5-10-5" fertilizer cannot be prepared, why not?

112. A hydrate of copper(II) sulfate, when heated, goes through the succession of changes suggested by the photograph. In this photograph, **(a)** is the original fully hydrated copper(II) sulfate; **(b)** is the product obtained by heating the original hydrate to 140 °C; **(c)** is the product obtained by further heating to 400 °C; and **(d)** is the product obtained at 1000 °C.



A 2.574 g sample of $CuSO_4 \cdot x\,H_2O$ was heated to 140 °C, cooled, and reweighed. The resulting solid was reheated to 400 °C, cooled, and reweighed. Finally, this solid was heated to 1000 °C, cooled, and reweighed for the last time.

Original sample	2.574 g
After heating to 140 °C	1.833 g
After reheating to 400 °C	1.647 g
After reheating to 1000 °C	0.812 g

(a) Assuming that all the water of hydration is driven off at 400 °C, what is the formula of the original hydrate?

(b) What is the formula of the hydrate obtained when the original hydrate is heated to only 140 °C?

(c) The black residue obtained at 1000 °C is an oxide of copper. What is its percent composition and empirical formula?

113. Some substances that are only very slightly soluble in water will spread over the surface of water to produce a film that is called a *monolayer* because it is only one molecule thick. A practical use of this phenomenon is to cover ponds to reduce the loss of water by evaporation. Stearic acid forms a monolayer on water. The molecules are arranged upright and in contact with one another, rather like pencils tightly packed and standing upright in a coffee mug. The model below represents an individual stearic acid molecule in the monolayer.

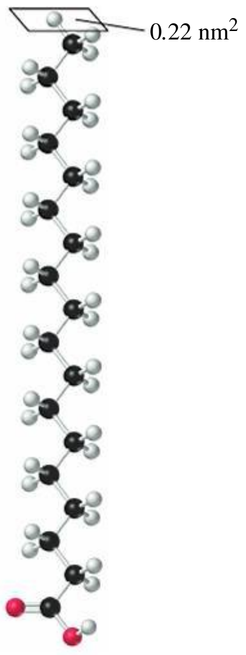
(a) How many square meters of water surface would be covered by a monolayer made from 10.0 g of stearic acid?
[*Hint:* What is the formula of stearic acid?]

(b) If stearic acid has a density of 0.85 g/cm^3, estimate the length (in nanometers) of a stearic acid molecule.
[*Hint:* What is the thickness of the monolayer described in part a?]

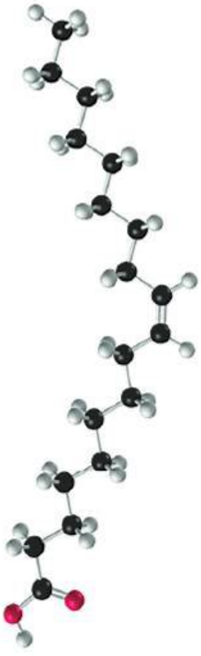
(c) A very dilute solution of oleic acid in liquid pentane is prepared in the following way:

$$\begin{aligned}
1.00\text{ mL oleic acid} &+ 9.00\text{ mL pentane} \rightarrow \text{solution (1)};\\
1.00\text{ mL solution (1)} &+ 9.00\text{ mL pentane} \rightarrow \text{solution (2)};\\
1.00\text{ mL solution (2)} &+ 9.00\text{ mL pentane} \rightarrow \text{solution (3)};\\
1.00\text{ mL solution (3)} &+ 9.00\text{ mL pentane} \rightarrow \text{solution (4)}.
\end{aligned}$$

A 0.10 mL sample of solution (4) is spread in a monolayer on water. The area covered by the monolayer is 85 cm^2. Assume that oleic acid molecules are arranged in the same way as described for stearic acid, and that the cross-sectional area of the molecule is 4.6×10^{-15} cm^2. The density of oleic acid is 0.895 g/mL. Use these data to obtain an approximate value of Avogadro's number.



Stearic acid



Oleic acid

Self-Assessment Exercises

114. In your own words, define or explain the following terms or symbols: **(a)** formula unit; **(b)** P_4; **(c)** molecular compound; **(d)** binary compound; **(e)** hydrate.

115. Briefly describe each of the following ideas or methods: **(a)** mole of a compound; **(b)** structural formula; **(c)** oxidation state; **(d)** carbon–hydrogen–oxygen determination by combustion analysis.

116. Explain the important distinctions between each pair of terms: **(a)** molecular mass and molar mass; **(b)** empirical and molecular formulas; **(c)** systematic and trivial, or common, name; **(d)** hydroxyl and carboxyl functional group.

117. Explain each term as it applies to the element nitrogen. **(a)** atomic mass; **(b)** molecular mass; **(c)** molar mass.

118. Which answer is correct? One mole of liquid bromine, Br_2, **(a)** has a mass of 79.9 g; **(b)** contains 6.022×10^{23} Br atoms; **(c)** contains the same number of atoms as in 12.01 g H_2O; **(d)** has twice the mass of 0.500 mole of gaseous Cl_2.

119. Three of the following formulas might be either an empirical or a molecular formula. The formula that must be a molecular formula is **(a)** N_2O; **(b)** N_2H_4; **(c)** NaCl; **(d)** NH_3.

120. The compound $C_7H_7NO_2$ contains **(a)** 17 atoms per mole; **(b)** equal percents by mass of C and H; **(c)** about twice the percent by mass of O as of N; **(d)** about twice the percent by mass of N as of H.

121. The greatest number of N atoms is found in **(a)** 50.0 g N_2O; **(b)** 17.0 g NH_3; **(c)** 150 mL of liquid pyridine, C_5H_5N ($d = 0.983$ g/mL); **(d)** 1.0 mol N_2.

122. XF_3 consists of 65% F by mass. The atomic mass of the element X must be **(a)** 8 u; **(b)** 11 u; **(c)** 31 u; **(d)** 35 u.

123. The oxidation state of I in the ion $H_4IO_6^-$ is **(a)** -1; **(b)** $+1$; **(c)** $+7$; **(d)** $+8$.

124. The formula for calcium chlorite is **(a)** $CaClO_2$; **(b)** $Ca(ClO_2)_2$; **(c)** $CaClO_3$; **(d)** $Ca(ClO_4)_2$.

125. A formula unit of the compound $[Cu(NH_3)_4]SO_4$ has nearly equal masses of **(a)** S and O; **(b)** N and O; **(c)** H and N; **(d)** Cu and O.

126. An isomer of the compound $CH_3CH_2CHOHCH_3$ is **(a)** $C_4H_{10}O$; **(b)** $CH_3CHOHCH_2CH_3$; **(c)** $CH_3(CH_2)_2OH$; **(d)** $CH_3CH_2OCH_2CH_3$.

127. A hydrate of Na_2SO_3 contains almost exactly 50% H_2O by mass. What is the formula of this hydrate?

128. Malachite is a common copper-containing mineral with the formula $CuCO_3 \cdot Cu(OH)_2$. **(a)** What is the mass percent copper in malachite? **(b)** When malachite is strongly heated, carbon dioxide and water are driven off, yielding copper(II) oxide as the sole product. What mass of copper(II) oxide is produced per kg of malachite?

129. Acetaminophen, an analgesic and antipyretic drug, has a molecular mass of 151.2 u and a mass percent composition of 63.56% C, 6.00% H, 9.27% N, and 21.17% O. What is the molecular formula of acetaminophen?

130. Ibuprofen is a compound used in painkillers. When a 2.174 g sample is burned in an excess of oxygen, it yields 6.029 g CO_2 and 1.709 g H_2O as the sole products. **(a)** What is the percent composition, by mass, of ibuprofen? **(b)** What is the empirical formula of ibuprofen?

131. Appendix E describes a useful study aid known as concept mapping. Using the method presented in Appendix E, construct a concept map illustrating the different concepts in Sections 3-2 and 3-3.

4

Chemical Reactions

The space shuttle *Discovery* lifts off on mission STS-26. Combustion reactions in the solid-fuel rocket engines provide the thrust to lift the shuttle off the launch pad. In this chapter, we learn to write and use balanced chemical equations for a wide variety of chemical reactions, including combustion reactions.

CONTENTS

4-1 Chemical Reactions and Chemical Equations
4-2 Chemical Equations and Stoichiometry
4-3 Chemical Reactions in Solution
4-4 Determining the Limiting Reactant
4-5 Other Practical Matters in Reaction Stoichiometry

We are all aware that iron rusts and natural gas burns. These processes are chemical reactions. Chemical reactions are the central concern not just of this chapter but of the entire science of chemistry. In this chapter, we will establish quantitative (numerical) relationships among the substances involved in a reaction, a topic known as *reaction stoichiometry*. Because many chemical reactions occur in solution, we will also consider *solution stoichiometry* and introduce a method of describing the composition of a solution called *solution molarity*.

In describing chemical reactions, we often take a microscopic view and focus on the entities—atoms, ions, or molecules—that make up the substances involved. However, when *doing* chemistry, we often think of reactions in more macroscopic terms because, in the laboratory, we handle quantities of substances—grams or liters—that can be easily measured or manipulated. In large part, reaction stoichiometry provides the relationships we need to relate macroscopic amounts of substances to our microscopic view of chemical reactions.

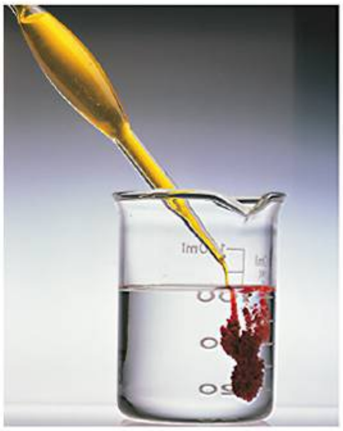
To some, stoichiometry is no more exciting than the law of conservation of mass, but make no mistake—stoichiometry is important. Chemists use stoichiometric principles routinely to plan experiments, analyze their results, and make predictions, all of which contribute to making new discoveries and expanding our knowledge of the microscopic world of atoms, molecules, and ions.

In this chapter, we will first learn to represent chemical reactions by chemical equations, and then we will use chemical equations—and ideas from earlier chapters—to establish the quantitative relationships we seek. Throughout the chapter, we will discuss new aspects of problem solving and more uses for the mole concept.

4-1 Chemical Reactions and Chemical Equations

A **chemical reaction** is a process in which one set of substances, called **reactants**, is converted to a new set of substances, called **products**. In other words, a chemical reaction is the process by which a chemical change occurs. In many cases, though, nothing happens when substances are mixed; each retains its original composition and properties. We need evidence before we can say that a reaction has occurred. Some of the types of physical evidence to look for are shown here:

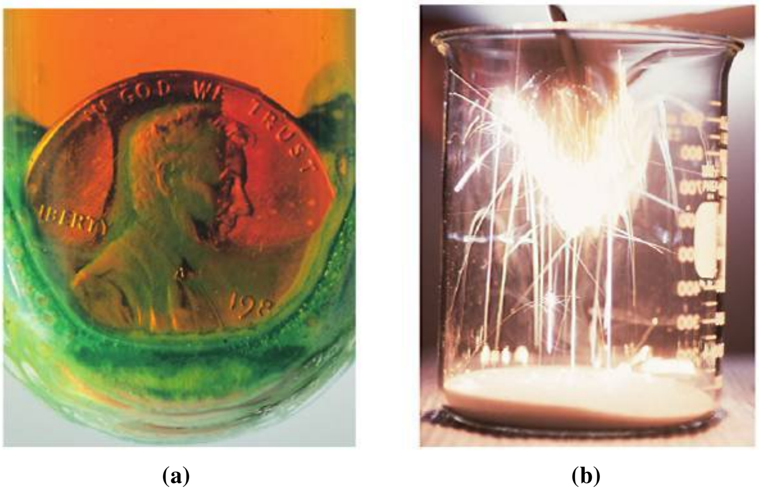
- a color change (Fig. 4-1)
- formation of a solid (precipitate) within a clear solution (Fig. 4-1)
- evolution of a gas (Fig. 4-2a)
- evolution or absorption of heat (Fig. 4-2b)



▲ FIGURE 4-1
Precipitation of silver chromate
When aqueous solutions of silver nitrate and potassium chromate are mixed, the disappearance of the distinctive yellow color of chromate ion and the appearance of the red-brown solid, silver chromate, provide physical evidence of a reaction.

Although such observations as these usually signify that a reaction has occurred, conclusive evidence still requires a detailed chemical analysis of the reaction mixture to identify all the substances present. Moreover, a chemical analysis may reveal that a chemical reaction has occurred even in the absence of obvious physical signs.

Just as there are symbols for elements and formulas for compounds, there is a symbolic, or shorthand, way of representing a chemical reaction—the **chemical equation**. In a chemical equation, formulas for the reactants are written on the left side of the equation and formulas for the products are written on the right. The two sides of the equation are joined by an arrow ($\longrightarrow$). We say that the reactants *yield* the products. Consider the reaction of colorless nitrogen



(a) (b)

▶ FIGURE 4-2
Evidence of a chemical reaction
(a) Evolution of a gas: When a copper penny reacts with nitric acid, the red-brown gas NO_2 is evolved. (b) Evolution of heat: When iron gauze (steel wool) is ignited in an oxygen atmosphere, evolved heat and light provide physical evidence of a reaction.

monoxide and oxygen gases to form red-brown nitrogen dioxide gas, a reaction that occurs in the manufacture of nitric acid.

$$\text{nitrogen monoxide} + \text{oxygen} \longrightarrow \text{nitrogen dioxide}$$

To complete the shorthand representation of this reaction, we must do two things:

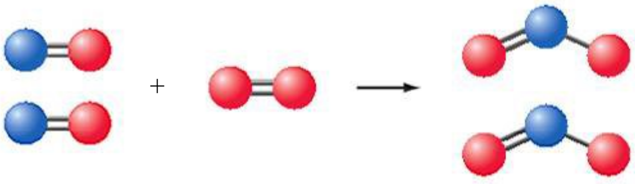
1. Substitute chemical formulas for names, to obtain the following expression.

   $$NO + O_2 \longrightarrow NO_2$$

   In this expression, there are three O atoms on the left side (one in the molecule NO and two in the molecule O_2), but only two O atoms (in the molecule NO_2) on the right. Because atoms are neither created nor destroyed in a chemical reaction, this expression needs to be *balanced*.

2. Balance the numbers of atoms of each kind on both sides of the expression to obtain a balanced chemical equation.* In this step, the coefficient two is placed in front of the formulas NO and NO_2. This means that two molecules of NO are consumed and two molecules of NO_2 are produced for every molecule of O_2 consumed. In the balanced equation there are two N atoms and four O atoms on each side. In a **balanced equation**, the total number of atoms of each element present is the same on both sides of the equation. We see this below, both in the symbolic equation and in the molecular representation of the reaction.

   $$2\,NO + O_2 \longrightarrow 2\,NO_2$$



The coefficients required to balance a chemical equation are called **stoichiometric coefficients**. These coefficients are essential in relating the amounts of reactants used and products formed in a chemical reaction, through a variety of calculations. In balancing a chemical equation, keep the following point in mind.

An equation can be balanced only by adjusting the coefficients of formulas.

The method of equation balancing described above is called *balancing by inspection*. Balancing by inspection means to adjust stoichiometric coefficients by trial and error until a balanced condition is found. Although the elements can generally be balanced in any order, equation balancing need not be a hit-or-miss affair. Here are some useful strategies for balancing equations.

- If an element occurs in only one compound on each side of the equation, try balancing this element first.
- When one of the reactants or products exists as the free element, balance this element last.
- In some reactions, certain groups of atoms (for example, polyatomic ions) remain unchanged. In such cases, balance these groups as a unit.

◀ Sometimes products react, partially or completely, to re-form the original reactants. Such reactions are called *reversible reactions* and are designated by a double arrow ($\rightleftharpoons$). In this chapter, we assume that any reverse reactions are negligible and that reactions go only in the forward direction. We consider reversible reactions in detail in Chapter 15.

◀ The reaction of NO and O_2 is of considerable environmental interest. Automobile engines—and all other combustion devices—make NO. One purpose of a catalytic converter is to reduce the amount of NO emitted from a tailpipe. Once in the atmosphere, NO is converted into brown NO_2 by the reaction illustrated on this page. This is why many urban atmospheres have a brown tinge.

---

*An equation—whether mathematical or chemical—must have the left and right sides equal. We should not call an expression an equation until it is balanced. The term *chemical equation* automatically signifies that this balance exists. Although unnecessary, the term *balanced* is commonly used when referring to a chemical equation.

- It is permissible to use fractional as well as integral numbers as coefficients. At times, an equation can be balanced most easily by using one or more fractional coefficients and then, if desired, clearing the fractions by multiplying *all* coefficients by a common multiplier.

▶ We will encounter a few situations in Chapters 7 and 19 where some fractional coefficients are actually required.

In this chapter you should concentrate on learning to write formulas for the reactants and products of a reaction and to balance the equation representing the reaction. A third task, which you will face in later chapters, is to predict the products formed when certain reactants are brought together under the appropriate conditions. Even now, however, based on concepts presented in the previous chapter, you should be able to predict the products of a *combustion reaction*. In a plentiful supply of oxygen gas, the combustion of hydrocarbons and of carbon–hydrogen–oxygen compounds produces carbon dioxide and water as the only products. If the compound contains sulfur as well, sulfur dioxide will also be a product. These ideas and an equation-balancing strategy are illustrated in Examples 4-1 and 4-2.

KEEP IN MIND

that the strategies described here work well for simple reactions. However, some reactions cannot be balanced by inspection and systematic methods must be employed. We will encounter such situations in Chapter 5.

EXAMPLE 4-1 Balancing an Equation

Ammonia and oxygen can react in several different ways, including the following. Balance the equation for this reaction.

$$NH_3 + O_2 \longrightarrow N_2 + H_2O$$

Analyze

We adjust the coefficients of NH_3, O_2, N_2, and H_2O to balance the numbers of atoms of each kind on both sides of the equation. There are three kinds of atoms: N, H, and O. The chemical equation is balanced only if it is balanced with respect to each kind of atom.

Solve

Since there is *one* N atom in NH_3 on the left, and *two* N atoms in N_2 on the right, the coefficient 2 must be added in front of NH_3.

$$2\,NH_3 + O_2 \longrightarrow N_2 + H_2O$$

Since there are *six* H atoms (in $2\,NH_3$) on the left of the equation just written and only *two* on the right (in H_2O), the coefficient 3 must be added in front of H_2O.

$$2\,NH_3 + O_2 \longrightarrow N_2 + 3\,H_2O$$

There are now *two* O atoms on the left (in O_2) and *three* O atoms on the right (in $3\,H_2O$). Three O atoms can be shown on the left by placing the coefficient $\frac{3}{2}$ in front of O_2.

$$2\,NH_3 + \tfrac{3}{2}O_2 \longrightarrow N_2 + 3\,H_2O \quad \text{(balanced)}$$

Multiply all the coefficients by 2 to produce a balanced equation in which all the coefficients are integers.

$$4\,NH_3 + 3\,O_2 \longrightarrow 2\,N_2 + 6\,H_2O \quad \text{(balanced)}$$

Assess

Note that the final equation above is balanced, with four N atoms, twelve H atoms, and six O atoms on each side.

PRACTICE EXAMPLE A: Balance the equations.

(a) $H_3PO_4 + CaO \longrightarrow Ca_3(PO_4)_2 + H_2O$

(b) $C_3H_8 + O_2 \longrightarrow CO_2 + H_2O$

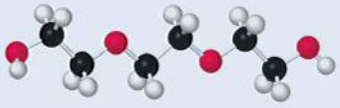
PRACTICE EXAMPLE B: Balance the equations.

(a) $NH_3 + O_2 \longrightarrow NO_2 + H_2O$

(b) $NO_2 + NH_3 \longrightarrow N_2 + H_2O$

EXAMPLE 4-2 Writing and Balancing an Equation: The Combustion of a Carbon–Hydrogen–Oxygen Compound

Liquid triethylene glycol is used as a solvent and plasticizer for vinyl and polyurethane plastics. Write a balanced chemical equation for the combustion of this compound in a plentiful supply of oxygen. A ball-and-stick model of triethylene glycol is shown here.



Triethylene glycol

Analyze

We deduce the formula of triethylene glycol from the molecular model. (Refer to the color scheme given on the inside back cover.) We see 6 C atoms (black), 4 O atoms (red), and 14 H atoms. The formula is $C_6H_{14}O_4$. When a carbon–hydrogen–oxygen compound is burned in excess oxygen, O_2, the products are CO_2 and H_2O.

Solve

Having identified the reactants and products, we write down an unbalanced chemical equation for the reaction, showing all reactants and products, and then we balance the equation with respect to each kind of atom.

Starting expression: $C_6H_{14}O_4 + O_2 \longrightarrow CO_2 + H_2O$

Balance C: $C_6H_{14}O_4 + O_2 \longrightarrow 6\,CO_2 + H_2O$

Balance H: $C_6H_{14}O_4 + O_2 \longrightarrow 6\,CO_2 + 7\,H_2O$

At this point, the right side of the expression has 19 O atoms (12 in six CO_2 molecules and 7 in seven H_2O molecules), and the left side, only 4 O atoms (in $C_6H_{14}O_4$). To obtain 15 more O atoms requires a fractional coefficient of 15/2 for O_2.

Balance O: $C_6H_{14}O_4 + \frac{15}{2}O_2 \longrightarrow 6\,CO_2 + 7\,H_2O$ (balanced)

To remove the fractional coefficient, multiply all coefficients by two:

$$2\,C_6H_{14}O_4 + 15\,O_2 \longrightarrow 12\,CO_2 + 14\,H_2O \quad \text{(balanced)}$$

Assess

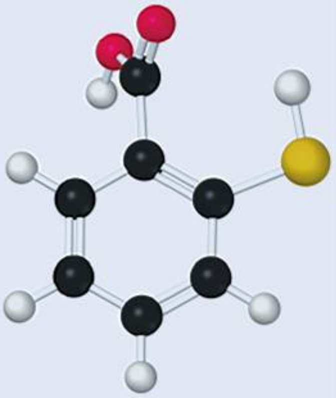
To check that the equation is balanced, determine the numbers of C, H, and O atoms that appear on the each side of the equation.

Left: $(2 \times 6) = 12\text{ C}; \quad (2 \times 14) = 28\text{ H}; \quad [(2 \times 4) + (15 \times 2)] = 38\text{ O}$

Right: $(12 \times 1) = 12\text{ C}; \quad (14 \times 2) = 28\text{ H}; \quad [(12 \times 2) + (14 \times 1)] = 38\text{ O}$

PRACTICE EXAMPLE A: Write a balanced equation to represent the reaction of mercury(II) sulfide and calcium oxide to produce calcium sulfide, calcium sulfate, and mercury metal.

PRACTICE EXAMPLE B: Write a balanced equation for the combustion of thiosalicylic acid, $C_7H_6O_2S$, used in the manufacture of indigo dyes. A ball-and-stick model of $C_7H_6O_2S$ is shown here.



Thiosalicylic acid

States of Matter

Ammonia (Example 4-1) is a gas at 25 °C, but triethylene glycol (Example 4-2) is a liquid. Such facts as these are inconsequential if our interest is only in balancing an equation. Still, we convey a more complete representation of the reaction by including this information, and sometimes it is essential to include such information in a chemical equation. The state of matter or physical form of reactants and products is shown by symbols in parentheses.

(g) gas (l) liquid (s) solid

Thus, the equation for combustion of triethylene glycol can be written as

$$2\,C_6H_{14}O_4(l) + 15\,O_2(g) \longrightarrow 12\,CO_2(g) + 14\,H_2O(l)$$

Another commonly used symbol for reactants or products dissolved in water is

(aq) *aqueous* solution

◀ At the high combustion temperature, water is present as $H_2O(g)$. But when the reaction products are returned to the initial temperature, the water condenses to a liquid, $H_2O(l)$.

Reaction Conditions

The equation for a chemical reaction does not provide enough information to enable you to carry out the reaction in a laboratory or chemical plant. An important aspect of modern chemical research involves working out the conditions for a reaction. The reaction conditions are often written above or below the arrow in an equation. For example, the Greek capital letter delta, Δ, means that a high temperature is required—that is, the reaction mixture must be heated, as in the decomposition of silver oxide.

$$2\,\mathrm{Ag_2O(s)} \xrightarrow{\Delta} 4\,\mathrm{Ag(s)} + \mathrm{O_2(g)}$$

▶ In a *decomposition reaction*, a substance is broken down into simpler substances (for instance, into its elements).

▶ In a *synthesis reaction*, a new compound is formed from the reaction of two or more simpler substances, usually called the reactants or starting materials.

An even more explicit statement of reaction conditions is shown below for the BASF (Badische Anilin & Soda-Fabrik) process for the synthesis of methanol from CO and H_2. This reaction occurs at 350 °C, under a total gas pressure that is 340 times as great as the normal pressure of the atmosphere, and on the surface of a mixture of ZnO and Cr_2O_3 acting as a *catalyst*. As we will learn later in the text, a catalyst is a substance that enters into a reaction in such a way that it speeds up the reaction without itself being consumed or changed by the reaction.

$$\mathrm{CO(g)} + 2\,\mathrm{H_2}(g) \xrightarrow[\substack{340\ \mathrm{atm} \\ \mathrm{ZnO,\ Cr_2O_3}}]{350\ ^\circ\mathrm{C}} \mathrm{CH_3OH(g)}$$

It is important to be able to calculate how much of a particular product will be produced when certain quantities of the reactants are consumed. In the next section, we will see how to use chemical equations to set up conversion factors that we can use for these and related calculations.

4-1 CONCEPT ASSESSMENT

For the elements K, Cl, and O in the following equations, the requirement that the number of atoms be equal on either side of the equation is met. Why is none of them an acceptable balanced equation for the decomposition of solid potassium chlorate yielding solid potassium chloride and oxygen gas?

(a) $\mathrm{KClO_3(s)} \longrightarrow \mathrm{KCl(s)} + 3\,\mathrm{O(g)}$

(b) $\mathrm{KClO_3(s)} \longrightarrow \mathrm{KCl(s)} + \mathrm{O_2(g)} + \mathrm{O(g)}$

(c) $\mathrm{KClO_3(s)} \longrightarrow \mathrm{KClO(s)} + \mathrm{O_2(g)}$

4-2 Chemical Equations and Stoichiometry

In Greek, the word *stoicheion* means element. The term **stoichiometry** (stoy-key-om'-eh-tree) means, literally, to measure the elements—but from a practical standpoint, it includes all the quantitative relationships involving atomic and formula masses, chemical formulas, and chemical equations. We considered the quantitative meaning of chemical formulas in Chapter 3, and now we will explore some additional quantitative aspects of chemical equations.

The coefficients in the chemical equation

$$2\,\mathrm{H_2(g)} + \mathrm{O_2(g)} \longrightarrow 2\,\mathrm{H_2O(l)} \qquad \textbf{(4.1)}$$

mean that

$$2x \text{ molecules } \mathrm{H_2} + x \text{ molecules } \mathrm{O_2} \longrightarrow 2x \text{ molecules } \mathrm{H_2O}$$

Suppose we let $x = 6.02214 \times 10^{23}$ (Avogadro's number). Then x molecules represents *1 mole*. Thus the chemical equation also means that

$$2 \text{ mol } H_2 + 1 \text{ mol } O_2 \longrightarrow 2 \text{ mol } H_2O$$

The coefficients in the chemical equation allow us to make statements such as

- *Two* moles of H_2O are *produced* for every *two* moles of H_2 *consumed*.
- *Two* moles of H_2O are *produced* for every *one* mole of O_2 *consumed*.
- *Two* moles of H_2 are *consumed* for every *one* mole of O_2 *consumed*.

Moreover, we can turn such statements into conversion factors, called stoichiometric factors. A **stoichiometric factor** relates the amounts, on a mole basis, of any two substances involved in a chemical reaction; thus a stoichiometric factor is a mole ratio. In the following examples, stoichiometric factors are printed in blue.

EXAMPLE 4-3 Relating the Numbers of Moles of Reactant and Product

How many moles of CO_2 are produced in the combustion of 2.72 mol of triethylene glycol, $C_6H_{14}O_4$, in an excess of O_2?

Analyze

"An excess of O_2" means that there is more than enough O_2 available to permit the complete conversion of the triethylene glycol to CO_2 and H_2O. The factor for converting from moles of $C_6H_{14}O_4$ to moles of CO_2 is obtained from the balanced equation for the combustion reaction.

Solve

The first step in a stoichiometric calculation is to write a balanced equation for the reaction. The balanced chemical equation for the reaction is given below.

$$2\, C_6H_{14}O_4 + 15\, O_2 \longrightarrow 12\, CO_2 + 14\, H_2O$$

Thus, 12 mol CO_2 are produced for every 2 mol $C_6H_{14}O_4$ burned. The production of 12 mol CO_2 is equivalent to the consumption of 2 mol $C_6H_{14}O_4$; thus, the ratio 12 mol CO_2/2 mol $C_6H_{14}O_4$ converts from mol $C_6H_{14}O_4$ to mol CO_2.

$$? \text{ mol } CO_2 = 2.72 \text{ mol } C_6H_{14}O_4 \times \frac{12 \text{ mol } CO_2}{2 \text{ mol } C_6H_{14}O_4} = 16.3 \text{ mol } CO_2$$

Assess

The expression above can be written in terms of two equal ratios:

$$\frac{? \text{ mol } CO_2}{2.72 \text{ mol } C_6H_{14}O_4} = \frac{12 \text{ mol } CO_2}{2 \text{ mol } C_6H_{14}O_4}$$

You may find it easier to set up an expression in terms of ratios and then solve it for the unknown quantity.

PRACTICE EXAMPLE A: How many moles of O_2 are produced from the decomposition of 1.76 moles of potassium chlorate?

$$2\, KClO_3(s) \longrightarrow 2\, KCl(s) + 3\, O_2(g)$$

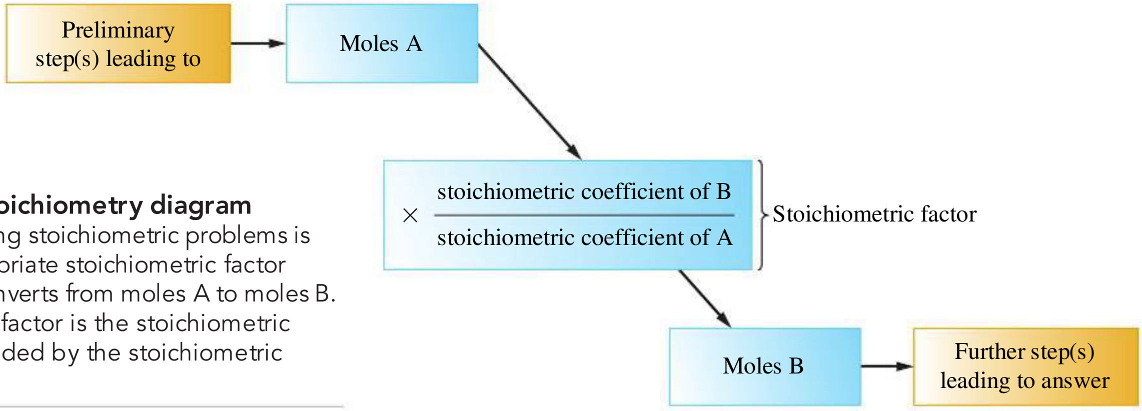
PRACTICE EXAMPLE B: How many moles of Ag are produced in the decomposition of 1.00 kg of silver(I) oxide?

$$2\, Ag_2O(s) \longrightarrow 4\, Ag(s) + O_2(g)$$

Reaction stoichiometry problems range from relatively simple to complex, yet all can be solved by the same general strategy. This strategy, outlined in Figure 4-3, yields information about one substance, B, from information given about a second substance, A. Thus, the conversion pathway is from the *known* A to the *unknown* B. The heart of the calculation, shown in blue in Figure 4-3, is conversion from the number of moles of A to the number of moles of B using a

KEEP IN MIND

that it is important to include units and to work from a balanced chemical equation when solving stoichiometry problems.



Preliminary step(s) leading to
Moles A
× stoichiometric coefficient of B / stoichiometric coefficient of A
Stoichiometric factor
Moles B
Further step(s) leading to answer

▶ FIGURE 4-3
A generalized stoichiometry diagram
A key step in working stoichiometric problems is applying the appropriate stoichiometric factor (mole ratio) that converts from moles A to moles B. The stoichiometric factor is the stoichiometric coefficient of B divided by the stoichiometric coefficient of A.

factor based on stoichiometric coefficients from the balanced chemical equation—that is, (stoichiometric coefficient of B)/(stoichiometric coefficient of A). Example 4-3 was a single-step calculation requiring only the stoichiometric factor. Examples 4-4 through 4-7 require additional steps, both before and after the stoichiometric factor is employed. In short, this strategy involves the following conversions: “to moles,” “between moles,” and “from moles.” The conversions can be done separately or they can be combined into a single-step calculation, as shown in the following examples.

EXAMPLE 4-4 Relating the Mass of a Reactant and a Product

What mass of CO_2 is formed in the reaction of 4.16 g triethylene glycol, $C_6H_{14}O_4$, with an excess of O_2?

Analyze

The general strategy involves the following conversions: (1) to moles, (2) between moles, and (3) from moles. In this example, the required conversions are $\text{g } C_6H_{14}O_4 \xrightarrow{1} \text{mol } C_6H_{14}O_4 \xrightarrow{2} \text{mol } CO_2 \xrightarrow{3} \text{g } CO_2$. Each numbered arrow refers to a conversion factor that changes the unit on the left to the one on the right.

Solve

The conversions can be carried out by using either a stepwise approach or the conversion pathway approach. Using a *stepwise approach*, we proceed as follows.

Convert from grams of $C_6H_{14}O_4$ to moles of $C_6H_{14}O_4$ by using the molar mass of $C_6H_{14}O_4$ as a conversion factor.

$$? \text{ mol } C_6H_{14}O_4 = 4.16 \text{ g } C_6H_{14}O_4 \times \frac{1 \text{ mol } C_6H_{14}O_4}{150.2 \text{ g } C_6H_{14}O_4}$$
$$= 0.0277 \text{ mol } C_6H_{14}O_4$$

Convert from moles of $C_6H_{14}O_4$ to moles of CO_2 by using the stoichiometric factor.

$$? \text{ mol } CO_2 = 0.0277 \text{ mol } C_6H_{14}O_4 \times \frac{12 \text{ mol } CO_2}{2 \text{ mol } C_6H_{14}O_4}$$
$$= 0.166 \text{ mol } CO_2$$

Convert from moles of CO_2 to grams of CO_2 by using the molar mass of CO_2 as a conversion factor.

$$? \text{ g } CO_2 = 0.166 \text{ mol } CO_2 \times \frac{44.01 \text{ g } CO_2}{1 \text{ mol } CO_2}$$
$$= 7.31 \text{ g } CO_2$$

In the *conversion pathway* approach, the individual steps are combined into a single line calculation, as shown below.

$$? \text{ g } CO_2 = 4.16 \text{ g } C_6H_{14}O_4 \times \underbrace{\frac{1 \text{ mol } C_6H_{14}O_4}{150.2 \text{ g } C_6H_{14}O_4}}_{\text{converts to moles of } C_6H_{14}O_4} \times \underbrace{\frac{12 \text{ mol } CO_2}{2 \text{ mol } C_6H_{14}O_4}}_{\text{converts to moles of } CO_2} \times \underbrace{\frac{44.01 \text{ g } CO_2}{1 \text{ mol } CO_2}}_{\text{converts to grams of } CO_2} = 7.31 \text{ g } CO_2$$

Note the connection between the stepwise approach and the conversion pathway approach for this problem. In the conversion pathway approach, the first conversion factor converts from grams of $C_6H_{14}O_4$ to moles of $C_6H_{14}O_4$. The second conversion factor is the stoichiometric factor, and it converts from moles of $C_6H_{14}O_4$ to moles of CO_2. The third conversion factor converts from moles of CO_2 to grams of CO_2. The conversion pathway approach combines all three calculations into a single line.

Assess

A quick scan of the numbers to the right of 4.16 g $C_6H_{14}O_4$ indicates that the stoichiometric factor has a value of 6; 6×44.01 is between 250 and 300 which, when divided by 150.2, yields a factor somewhat smaller than 2. The mass of CO_2 should be somewhat less than twice that of the $C_6H_{14}O_4$, and it is (compare 7.31 to 2×4.16). Also, note that all units cancel properly in the ultimate conversion from g $C_6H_{14}O_4$ to g CO_2.

PRACTICE EXAMPLE A: How many grams of magnesium nitride, Mg_3N_2, are produced by the reaction of 3.82 g Mg with an excess of N_2?

PRACTICE EXAMPLE B: How many grams of $H_2(g)$ are required to produce 1.00 kg methanol, CH_3OH, by the reaction $CO + 2\,H_2 \longrightarrow CH_3OH$?

EXAMPLE 4-5 Relating the Masses of Two Reactants to Each Other

What mass of O_2 is consumed in the complete combustion of 6.86 g of triethylene glycol, $C_6H_{14}O_4$?

Analyze

The required conversions are $\text{g } C_6H_{14}O_4 \xrightarrow{1} \text{mol } C_6H_{14}O_4 \xrightarrow{2} \text{mol } O_2 \xrightarrow{3} \text{g } O_2$.

Solve

We will first use a stepwise approach to solve this problem.

Convert from grams of $C_6H_{14}O_4$ to moles of $C_6H_{14}O_4$ by using the molar mass of $C_6H_{14}O_4$ as a conversion factor.

$$? \text{ mol } C_6H_{14}O_4 = 6.86 \text{ g } C_6H_{14}O_4 \times \frac{1 \text{ mol } C_6H_{14}O_4}{150.2 \text{ g } C_6H_{14}O_4}$$
$$= 0.0457 \text{ mol } C_6H_{14}O_4$$

Convert from moles of $C_6H_{14}O_4$ to moles of O_2 by using the stoichiometric factor.

$$? \text{ mol } O_2 = 0.0457 \text{ mol } C_6H_{14}O_4 \times \frac{15 \text{ mol } O_2}{2 \text{ mol } C_6H_{14}O_4}$$
$$= 0.0343 \text{ mol } O_2$$

Convert from moles of O_2 to grams of O_2 by using the molar mass of O_2 as a conversion factor.

$$? \text{ g } O_2 = 0.343 \text{ mol } O_2 \times \frac{32.00 \text{ g } O_2}{1 \text{ mol } O_2}$$
$$= 11.0 \text{ g } O_2$$

As in Example 4-4, the three steps can be combined into a single calculation, as shown below.

$$? \text{ g } O_2 = 6.86 \text{ g } C_6H_{14}O_4 \times \frac{1 \text{ mol } C_6H_{14}O_4}{150.2 \text{ g } C_6H_{14}O_4} \times \frac{15 \text{ mol } O_2}{2 \text{ mol } C_6H_{14}O_6} \times \frac{32.00 \text{ g } O_2}{1 \text{ mol } O_2} = 11.0 \text{ g } O_2$$

Assess

Focus on the single line calculation shown above. A quick scan of the numbers to the right of 6.86 g $C_6H_{14}O_4$ indicates that the stoichiometric factor has a value of 7.5; the product, 7.5×32.00, is about 250, which, when divided by 150.2, yields a factor of about $250/150 = 5/3$. The mass of O_2 should be about 5/3 that of the $C_6H_{14}O_4$, and it is—that is, compare 11.0 with 5/3 of 6.86, which is about 35/3 or somewhat less than 12. As in Example 4-4, note that the proper cancellation of units occurs.

PRACTICE EXAMPLE A: For the reaction in Example 4-1, how many grams of NH_3 are consumed per gram of O_2?

PRACTICE EXAMPLE B: In the combustion of octane, C_8H_{18}, how many grams of O_2 are consumed per gram of octane?

4-2 CONCEPT ASSESSMENT

Which statements are correct for the reaction $2\,H_2S + SO_2 \longrightarrow 3\,S + 2\,H_2O$? Explain your reasoning.

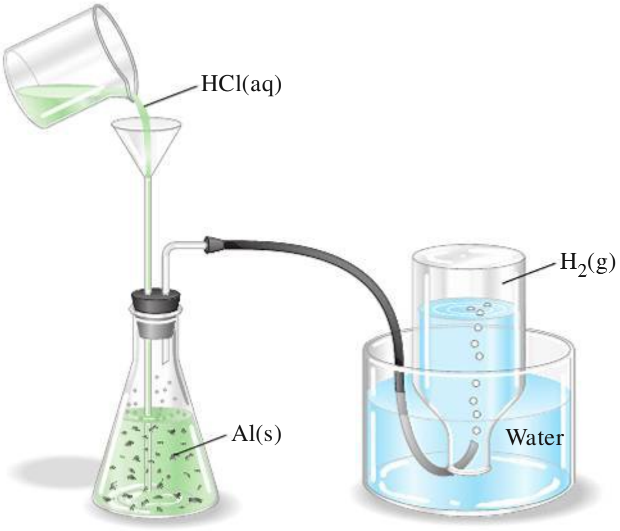
(a) 3 mol S is produced per mole of H_2S.
(b) 3 g S is produced for every gram of SO_2 consumed.
(c) 1 mol H_2O is produced per mole of H_2S consumed.
(d) Two-thirds of the S produced comes from H_2S.
(e) The number of moles of products formed equals the number of moles of reactants consumed.
(f) The number of moles of atoms present after the reaction is the same as the number of moles of atoms before the reaction.

What lends great variety to stoichiometric calculations is that many other conversions may be required before and after the mol A ⟶ mol B step at the center of the stoichiometric scheme shown in Figure 4-3. In Examples 4-4 and 4-5, the additional conversions involved molar mass. Other common conversions may require such factors as volume, density, and percent composition. In every case, however, we must always use the appropriate stoichiometric factor from the chemical equation as a key conversion factor.

The reaction between solid aluminum, Al(s), and aqueous hydrochloric acid, HCl(aq), can be used for preparing small volumes of hydrogen gas, $H_2(g)$, in the laboratory. A balanced chemical equation for the reaction is shown below.

$$2\,\text{Al(s)} + 6\,\text{HCl(aq)} \longrightarrow 2\,\text{AlCl}_3\text{(aq)} + 3\,\text{H}_2\text{(g)} \qquad \textbf{(4.2)}$$

A simple laboratory setup for collecting the hydrogen gas is pictured in Figure 4-4. The reaction between Al(s) and HCl(aq) provides a range of possibilities for calculations. Examples 4-6 and 4-7 are based on this reaction.



▲ FIGURE 4-4
The reaction $2\,\text{Al(s)} + 6\,\text{HCl(aq)} \longrightarrow 2\,\text{AlCl}_3\text{(aq)} + 3\,\text{H}_2\text{(g)}$
HCl(aq) is added to the flask on the left. The reaction occurs within the flask. The liberated $H_2(g)$ flows into a gas-collection apparatus, where it displaces water. Hydrogen is only very slightly soluble in water.

EXAMPLE 4-6 Additional Conversion Factors in a Stoichiometric Calculation: Volume, Density, and Percent Composition

An alloy used in aircraft structures consists of 93.7% Al and 6.3% Cu by mass. The alloy has a density of $2.85\ \mathrm{g/cm^3}$. A $0.691\ \mathrm{cm^3}$ piece of the alloy reacts with an excess of HCl(aq). If we assume that *all* the Al but *none* of the Cu reacts with HCl(aq), what is the mass of H_2 obtained? Refer to reaction (4.2).

Analyze

A simple approach to this calculation is outlined below. Each numbered arrow refers to a conversion factor that changes the unit on the left to the one on the right.

$$\mathrm{cm^3\ alloy} \xrightarrow{1} \mathrm{g\ alloy} \xrightarrow{2} \mathrm{g\ Al} \xrightarrow{3} \mathrm{mol\ Al} \xrightarrow{4} \mathrm{mol\ H_2} \xrightarrow{5} \mathrm{g\ H_2}$$

The calculation can be done in five distinct steps, or with a single setup in which the five conversions are performed in sequence.

Solve

Using a stepwise approach, we proceed as follows.

Convert from volume of alloy to grams of alloy by using the density as a conversion factor.

$$?\ \mathrm{g\ alloy} = 0.691\ \mathrm{cm^3\ alloy} \times \frac{2.85\ \mathrm{g\ alloy}}{1\ \mathrm{cm^3\ alloy}} = 1.97\ \mathrm{g\ alloy}$$

Convert from grams of alloy to grams of Al by using the percentage by mass of Al as a conversion factor.

$$?\ \mathrm{g\ Al} = 1.97\ \mathrm{g\ alloy} \times \frac{93.7\ \mathrm{g\ Al}}{100\ \mathrm{g\ alloy}} = 1.85\ \mathrm{g\ Al}$$

Convert from grams of Al to moles of Al by using the molar mass as a conversion factor.

$$?\ \mathrm{mol\ Al} = 1.85\ \mathrm{g\ Al} \times \frac{1\ \mathrm{mol\ Al}}{26.98\ \mathrm{g\ Al}} = 0.0684\ \mathrm{mol\ Al}$$

Convert from moles of Al to moles of H_2 by using the stoichiometric factor.

$$?\ \mathrm{mol\ H_2} = 0.0684\ \mathrm{mol\ Al} \times \frac{3\ \mathrm{mol\ H_2}}{2\ \mathrm{mol\ Al}} = 0.103\ \mathrm{mol\ H_2}$$

Convert from moles of Al to moles of H_2 by using the stoichiometric factor.

$$?\ \mathrm{g\ H_2} = 0.103\ \mathrm{mol\ H_2} \times \frac{2.016\ \mathrm{g\ H_2}}{1\ \mathrm{mol\ H_2}} = 0.207\ \mathrm{g\ H_2}$$

Remember to store intermediate results without rounding off. When all of the steps are combined into a single calculation, we do not have to write down intermediate results and we reduce rounding errors.

$$?\ \mathrm{g\ H_2} = 0.691\ \mathrm{cm^3\ alloy} \times \frac{2.85\ \mathrm{g\ alloy}}{1\ \mathrm{cm^3\ alloy}} \times \frac{93.7\ \mathrm{g\ Al}}{100\ \mathrm{g\ alloy}} \times \frac{1\ \mathrm{mol\ Al}}{26.98\ \mathrm{g\ Al}} \times \frac{3\ \mathrm{mol\ H_2}}{2\ \mathrm{mol\ Al}} \times \frac{2.016\ \mathrm{g\ H_2}}{1\ \mathrm{mol\ H_2}}$$
$$= 0.207\ \mathrm{g\ H_2}$$

Assess

The units work out properly, but we must evaluate whether the answer is a reasonable one. The molar masses of Al and H_2 are approximately 27 g/mol and 2 g/mol, respectively. Equation (4.2) tells us that 1 mole of Al, which weighs approximately 27 g, produces 1.5 mol of H_2, which weighs $1.5 \times 2 = 3$ g. Thus, 27 g Al produces approximately 3 g H_2 and, thus, 2.7 g Al produces approximately 0.3 g H_2. In this example, we are dealing with less than 2.7 g of Al; therefore, we expect less than 0.3 g of H_2. The answer, 0.207 g H_2, is reasonable.

PRACTICE EXAMPLE A: What volume of the aluminum-copper alloy described in Example 4-6 must be dissolved in an excess of HCl(aq) to produce 1.00 g H_2?

[*Hint:* Think of this as the "inverse" of Example 4-6.]

PRACTICE EXAMPLE B: A fresh sample of the aluminum-copper alloy described in Example 4-6 yielded 1.31 g H_2. How many grams of copper were present in the sample?

EXAMPLE 4-7 Additional Conversion Factors in a Stoichiometric Calculation: Volume, Density, and Percent Composition of a Solution

A hydrochloric acid solution consists of 28.0% HCl by mass and has a density of 1.14 g/mL. What volume of this solution is required to react completely with 1.87 g Al in reaction (4.2)?

Analyze

The first challenge here is to determine where to begin. Although the problem refers to 28.0% HCl and a density of 1.14 g/mL, the appropriate starting point is with the given information—1.87 g Al. The goal of our calculation is a solution volume—mL HCl solution.

$$\text{g Al} \xrightarrow{1} \text{mol Al} \xrightarrow{2} \text{mol HCl} \xrightarrow{3} \text{g HCl} \xrightarrow{4} \text{g HCl solution} \xrightarrow{5} \text{mL HCl solution}$$

The conversion factors in the calculation involve (1) the molar mass of Al, (2) stoichiometric coefficients from equation (4.2), (3) the molar mass of HCl, (4) the percent composition of the HCl solution, and (5) the density of the HCl solution.

Solve

Using a stepwise approach, we proceed as follows.

Convert from grams of Al to moles of Al by using the molar mass of Al.

$$?\ \text{mol Al} = 1.87\ \text{g Al} \times \frac{1\ \text{mol Al}}{26.98\ \text{g Al}} = 0.0693\ \text{mol Al}$$

Convert from moles of Al to moles of HCl by using the stoichiometric factor.

$$?\ \text{mol HCl} = 0.0693\ \text{mol Al} \times \frac{6\ \text{mol HCl}}{2\ \text{mol Al}} = 0.208\ \text{mol HCl}$$

Convert from moles of HCl to grams of HCl by using the molar mass of HCl.

$$?\ \text{g HCl} = 0.208\ \text{mol HCl} \times \frac{36.46\ \text{g HCl}}{1\ \text{mol HCl}} = 7.58\ \text{g HCl}$$

Convert from grams of HCl to grams of HCl solution by using the percentage by mass.

$$?\ \text{g HCl soln} = 7.58\ \text{g HCl} \times \frac{100\ \text{g HCl soln}}{28.0\ \text{g HCl}}$$
$$= 27.1\ \text{g HCl soln}$$

Convert from grams of HCl solution to milliliters of HCl solution by using the density.

$$?\ \text{mL HCl soln} = 27.1\ \text{g HCl soln} \times \frac{1\ \text{mL HCl soln}}{1.14\ \text{g HCl soln}}$$
$$= 23.8\ \text{mL HCl soln}$$

In the conversion pathway approach, we combine the individual steps into a single line.

$$(\text{g Al} \xrightarrow{1} \text{mol Al} \xrightarrow{2} \text{mol HCl} \xrightarrow{3} \text{g HCl}$$
$$?\ \text{mL HCl soln} = 1.87\ \text{g Al} \times \frac{1\ \text{mol Al}}{26.98\ \text{g Al}} \times \frac{6\ \text{mol HCl}}{2\ \text{mol Al}} \times \frac{36.46\ \text{g HCl}}{1\ \text{mol HCl}}$$
$$\xrightarrow{4} \text{g HCl soln} \xrightarrow{5} \text{mL HCl soln})$$
$$\times \frac{100.0\ \text{g HCl soln}}{28.0\ \text{g HCl}} \times \frac{1\ \text{mL HCl soln}}{1.14\ \text{g HCl soln}}$$
$$= 23.8\ \text{mL HCl soln}$$

Assess

Let's attempt to establish whether the answer is reasonable by working the problem in reverse and using numbers that are rounded off slightly. Because the density of the solution is approximately 1 g/mL and the solution is approximately 30% HCl by mass, a 24 mL sample of the solution will contain approximately $24 \times 0.30 = 7.2$ g of HCl. Equation (4.2) tells us that 1 mol Al, or 27 g Al, reacts with 3 mol HCl, or 108 g HCl. Stated another way, 4 g HCl reacts with 1 g Al. In this example, we are using approximately 7.2 g HCl; thus, we consume approximately $7.2\ \text{g HCl} \times 1\ \text{g Al}/4\ \text{g HCl} = 1.8\ \text{g Al}$. This value is close to the actual amount of Al consumed and we conclude that our answer, 23.8 mL of HCl solution, is reasonable.

PRACTICE EXAMPLE A: How many milligrams of H_2 are produced when one drop (0.05 mL) of the hydrochloric acid solution described in Example 4-7 reacts with an excess of aluminum in reaction (4.2)?

PRACTICE EXAMPLE B: A particular vinegar contains 4.0% CH_3COOH by mass. It reacts with sodium carbonate to produce sodium acetate, carbon dioxide, and water. How many grams of carbon dioxide are produced by the reaction of 5.00 mL of this vinegar with an excess of sodium carbonate? The density of the vinegar is 1.01 g/mL.

4-3 CONCEPT ASSESSMENT

Without performing detailed calculations, determine which reaction produces the maximum quantity of $O_2(g)$ per gram of reactant.

(a) $2\ NH_4NO_3(s) \xrightarrow{\Delta} 2\ N_2(g) + 4\ H_2O(l) + O_2(g)$

(b) $2\ Ag_2O(s) \xrightarrow{\Delta} 4\ Ag(s) + O_2(g)$

(c) $2\ HgO(s) \xrightarrow{\Delta} 2\ Hg(l) + O_2(g)$

(d) $2\ Pb(NO_3)_2(s) \xrightarrow{\Delta} 2\ PbO(s) + 4\ NO_2(g) + O_2(g)$

4-3 Chemical Reactions in Solution

Most reactions in the general chemistry laboratory are carried out in solutions. This is partly because mixing the reactants in solution helps to achieve the close contact between atoms, ions, or molecules necessary for a reaction to occur. The stoichiometry of reactions in solutions can be described in the same way as the stoichiometry of other reactions, as we saw in Example 4-7. A few new ideas that apply specifically to solution stoichiometry are also helpful.

One component of a solution, called the **solvent**, determines whether the solution exists as a solid, liquid, or gas. In this discussion we will limit ourselves to *aqueous solutions*—solutions in which liquid water is the solvent. The other components of a solution, called **solutes**, are dissolved in the solvent. We use the notation NaCl(aq), for example, to describe a solution in which liquid water is the solvent and NaCl is the solute. The term *aqueous* does not convey any information, however, about the relative proportions of NaCl and H_2O in the solution. For this purpose, the property called *molarity* is commonly used.

Molarity

The composition of a solution may be specified by giving its molarity, which is defined as the amount of solute, in moles, per liter of solution:

$$\text{molarity} = \frac{\text{amount of solute (in moles)}}{\text{volume of solution (in liters)}}$$

The expression above can be written more compactly as

$$M = \frac{n}{V} \qquad \textbf{(4.3)}$$

◀ The IUPAC-preferred term for molarity is *amount concentration*, and the preferred symbol is *C*, although many use *M*. Be sure to maintain a clear distinction between the *property* concentration (molarity) $= C = M = n/V$ and the *unit* in which it is expressed, molarity $=$ M $=$ mol/L.

where *M* is the molarity in moles per liter (mol/L), *n* is the amount of solute in moles (mol), and *V* is the volume of the solution in liters (L).

If 0.440 mol urea, $CO(NH_2)_2$, is dissolved in enough water to make 1.000 L of solution, the solution concentration, or molarity, is

$$\frac{0.440\ \text{mol}\ CO(NH_2)_2}{1.000\ \text{L soln}} = 0.440\ \text{M}\ CO(NH_2)_2$$

The symbol M stands for the term *molar*, or mol/L. Thus, a solution that has 0.440 mol $CO(NH_2)_2$/L is 0.440 M $CO(NH_2)_2$ or 0.440 molar $CO(NH_2)_2$. Notice that molarity (*M*) has units mol/L or M. In this text, we use the symbol *M* (in italics) to represent molarity and the symbol M (no italics) as an abbreviation for the unit mol/L.

Alternatively, if 0.110 mol urea is present in 250.0 mL of solution, the solution is also 0.440 M.

$$\frac{0.110\ \text{mol}\ CO(NH_2)_2}{0.2500\ \text{L soln}} = 0.440\ \text{M}\ CO(NH_2)_2$$

KEEP IN MIND

that the volume used in molarity is that of the *solution*. It is neither that of the solvent used, nor the sum of the volumes of the solvent and solute. For example, if we add 25.0 mL ethanol to 250.0 mL water, the solution volume will be neither 250.0 mL nor 275.0 mL. We learn why in Chapter 13.

When calculating concentration, we must determine the amount of solute in moles from other quantities that can be readily measured, such as the mass of solute or the volume of a liquid solute. In Example 4-8, the mass of a liquid solute is related to its volume by using density as a conversion factor. Then, molar mass is used to convert from the mass of solute to an amount of solute in moles. Also, the solution volume is converted from milliliters (mL) to liters (L).

Figure 4-5 illustrates a method commonly used to prepare a solution. A solid sample is weighed out and dissolved in sufficient water to produce a solution of known volume—250.0 mL. To fill a beaker to a 250 mL mark is not nearly precise enough as a volume measurement. As discussed in Section 1-6, there would be a systematic error because the beaker is not calibrated with sufficient precision. (The error in volume could be 10 to 20 mL or more.) To dissolve the solute in water and bring the solution level to the 250 mL mark in a graduated cylinder is also not sufficiently precise. Although the graduated cylinder is calibrated more precisely than the beaker, the error might still be 1 to 2 mL or more. However, when filled to the calibration mark, the volumetric flask pictured in Figure 4-5 contains 250.0 mL with only about 0.1 mL of error.

When the molarity of a solution is known accurately, we can calculate the number of moles of solute in a carefully measured volume of solution by using the equation below.

$$n = M \times V \qquad \textbf{(4.4)}$$

The expression above is equivalent to equation (4.3), but equation (4.4) emphasizes that the molarity, M, is a conversion factor for converting from liters of solution to moles of solute. In Example 4-9, we use molarity as a conversion factor in a calculation to determine the mass of solute needed to produce the solution in Figure 4-5.

EXAMPLE 4-8 Calculating Molarity from Measured Quantities

A solution is prepared by dissolving 25.0 mL ethanol, CH_3CH_2OH ($d = 0.789$ g/mL), in enough water to produce 250.0 mL solution. What is the molarity of ethanol in the solution?

Analyze

We must first calculate how many moles of ethanol are in a 25.0 mL sample of pure ethanol. This calculation requires the following conversions: mL ethanol $\xrightarrow{1}$ g ethanol $\xrightarrow{2}$ mol ethanol. The first conversion uses the density as a conversion factor and the second conversion uses molar mass as a conversion factor. The molarity of the solution is then calculated by using equation (4.3).

Solve

The number of moles of ethanol in a 25.0 mL sample of pure ethanol is calculated below in a single line.

$$? \text{ mol } CH_3CH_2OH = 25.0 \text{ mL } CH_3CH_2OH \times \frac{0.789 \text{ g } CH_3CH_2OH}{1 \text{ mL } CH_3CH_2OH} \times \frac{1 \text{ mol } CH_3CH_2OH}{46.07 \text{ g } CH_3CH_2OH}$$
$$= 0.428 \text{ mol } CH_3CH_2OH$$

To apply the definition of molarity given in expression (4.3), note that 250.0 mL = 0.2500 L.

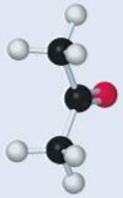
$$\text{molarity} = \frac{0.428 \text{ mol } CH_3CH_2OH}{0.2500 \text{ L soln}} = 1.71 \text{ M } CH_3CH_2OH$$

Assess

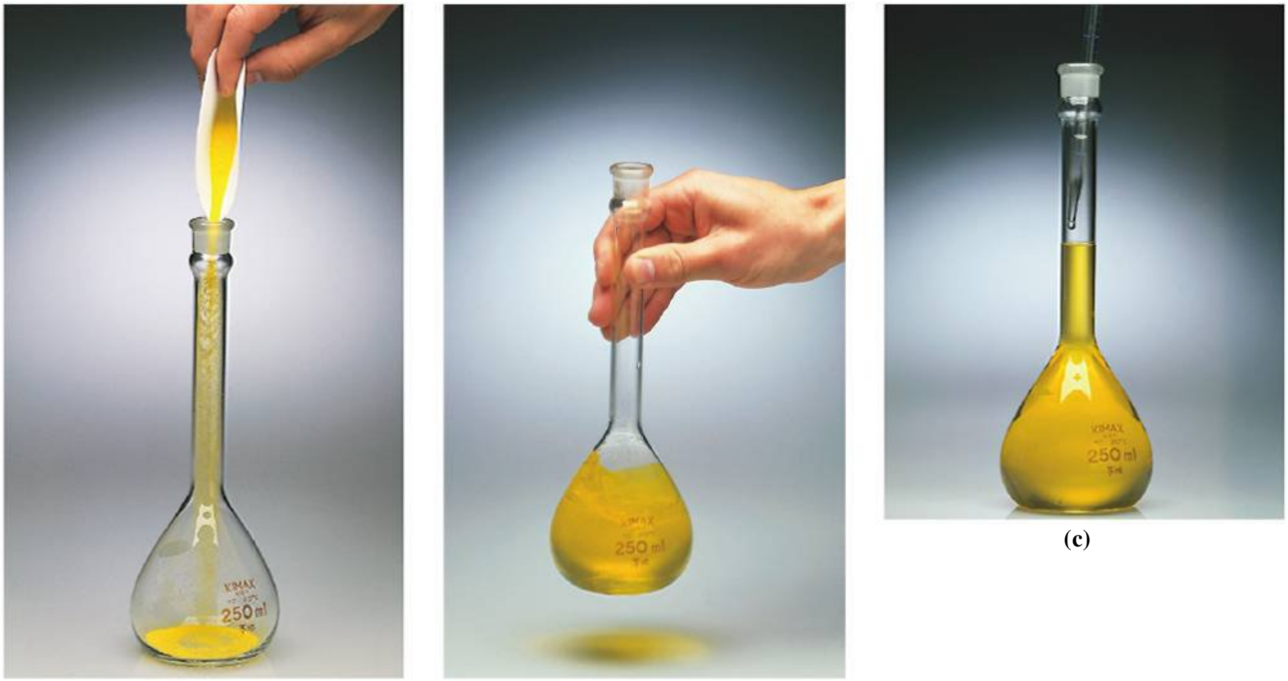
It is important to include the units in this calculation to ensure that we obtain the correct units for the final answer. When dealing with liquid solutes, be careful to distinguish between mL solute and mL soln.

PRACTICE EXAMPLE A: A 22.3 g sample of acetone (see the model here) is dissolved in enough water to produce 1.25 L of solution. What is the molarity of acetone in this solution?

PRACTICE EXAMPLE B: If 15.0 mL of acetic acid, CH_3COOH ($d = 1.048$ g/mL), is dissolved in enough water to produce 500.0 mL of solution, then what is the molarity of acetic acid in the solution?



Acetone



(a) (b) (c)

▲ FIGURE 4-5
Preparation of 0.250 M K_2CrO_4—Example 4-9 illustrated
The solution cannot be prepared just by adding 12.1 g $K_2CrO_4(s)$ to 250.0 mL water. Instead, (a) the weighed quantity of $K_2CrO_4(s)$ is first added to a clean, dry 250 mL volumetric flask; (b) the $K_2CrO_4(s)$ is dissolved in less than 250 mL of water; and (c) the flask is filled to the 250.0 mL calibration mark by the careful addition (dropwise) of the remaining water.

EXAMPLE 4-9 Calculating the Mass of Solute in a Solution of Known Molarity

What mass of K_2CrO_4 is needed to prepare exactly 0.2500 L (250.0 mL) of a 0.250 M K_2CrO_4 solution in water? (See Figure 4-5.)

Analyze

The conversion pathway is L soln → mol K_2CrO_4 → g K_2CrO_4. The first conversion factor is the molarity of the solution, shown below in blue, and the second conversion factor is the molar mass of K_2CrO_4.

Solve

$$? \text{ g } K_2CrO_4 = 0.2500 \text{ L soln} \times \frac{0.250 \text{ mol } K_2CrO_4}{1 \text{ L soln}} \times \frac{194.2 \text{ g } K_2CrO_4}{1 \text{ mol } K_2CrO_4}$$

$$= 12.1 \text{ g } K_2CrO_4$$

Assess

The answer has the correct units. We can check whether the answer is reasonable by working the problem in reverse and using numbers that are rounded off slightly. Because the molar mass of K_2CrO_4 is approximately 200 g/mol and the mass of the sample is approximately 12 g, the number of moles of K_2CrO_4 in the sample is approximately $12/200 = 6/100 = 0.06$ mol. The approximate molarity is $0.06/0.250 = 0.24$ mol/L. This estimate is close to the true molarity, and so we are confident that the answer, 12.1 g K_2CrO_4, is correct.

PRACTICE EXAMPLE A: An aqueous solution saturated with $NaNO_3$ at 25 °C is 10.8 M $NaNO_3$. What mass of $NaNO_3$ is present in 125 mL of this solution at 25 °C?

PRACTICE EXAMPLE B: What mass of $Na_2SO_4 \cdot 10\,H_2O$ is needed to prepare 355 mL of 0.445 M Na_2SO_4?

Solution Dilution

A common sight in chemistry storerooms and laboratories is rows of bottles containing solutions for use in chemical reactions. It is not practical, however, to store solutions of every possible concentration. Instead, most labs store fairly concentrated solutions, so-called *stock solutions*, which can then be used to prepare more dilute solutions by adding water. The principle of dilution, which you have probably already inferred, is that the same solute that was present in a sample of stock solution is distributed throughout the larger volume of a diluted solution (see Figure 4-6).

▶ A *concentrated solution* has a relatively large amount of dissolved solute; a *dilute solution* has a relatively small amount.

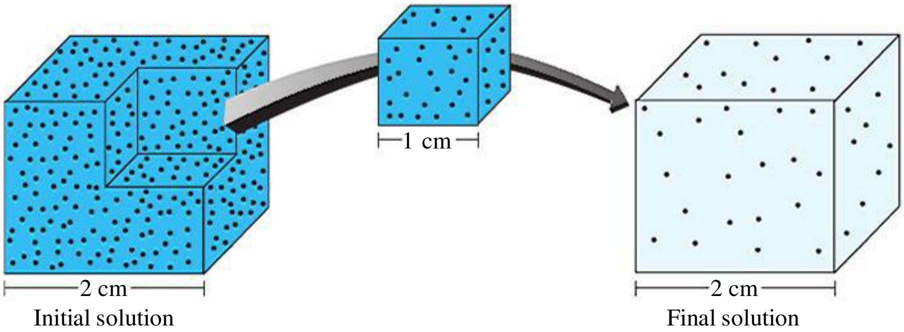
When a volume of a solution is diluted, the amount of solute *remains constant*. If we write equation (4.4) for the initial (i) undiluted solution, we obtain $n_{\mathrm{i}} = M_{\mathrm{i}}V_{\mathrm{i}}$; for the final (f) diluted solution, we obtain $n_{\mathrm{f}} = M_{\mathrm{f}}V_{\mathrm{f}}$. Because n_i is equal to n_f, we obtain the following result:

$$M_{\mathrm{i}}V_{\mathrm{i}} = M_{\mathrm{f}}V_{\mathrm{f}} \qquad \textbf{(4.5)}$$

Figure 4-7 illustrates the laboratory procedure for preparing a solution by dilution. Example 4-10 explains the necessary calculation.

KEEP IN MIND

that equation (4.5) applies only to dilution problems. An alternative expression uses the subscripts 1 and 2 in place of i and f: $M_1V_1 = M_2V_2$. Some students mistakenly use $M_1V_1 = M_2V_2$ to convert from moles of substance 1 to moles of substance 2 when doing stoichiometry problems. To avoid making this mistake, always use the subscripts "i" and "f" when using equation (4.5), or even better, use the subscripts "dil" (for diluted) and "conc" (for concentrated): $M_{\mathrm{dil}}V_{\mathrm{dil}} = M_{\mathrm{conc}}V_{\mathrm{conc}}$.



▲ FIGURE 4-6
Visualizing the dilution of a solution
The final solution is prepared by extracting $\frac{1}{8}$ of the initial solution—1 cm^3—and diluting it with water to a volume of 8 cm^3. The number of dots in the 8 cm^3 of final solution, representing the number of solute particles, is the same as in the 1 cm^3 of initial solution.

EXAMPLE 4-10 Preparing a Solution by Dilution

A particular analytical chemistry procedure requires 0.0100 M K_2CrO_4. What volume of 0.250 M K_2CrO_4 must be diluted with water to prepare 0.2500 L of 0.0100 M K_2CrO_4?

Analyze

First, we calculate the number of moles K_2CrO_4 that must be present in the final solution. Then, we calculate the volume of 0.250 M K_2CrO_4 that contains this amount of K_2CrO_4.

Solve

First, calculate the amount of solute that must be present in the final solution.

$$?\ \text{mol } K_2CrO_4 = 0.2500\ \text{L soln} \times \frac{0.0100\ \text{mol } K_2CrO_4}{1\ \text{L soln}} = 0.00250\ \text{mol } K_2CrO_4$$

Second, calculate the volume of 0.250 M K_2CrO_4 that contains 0.00250 mol K_2CrO_4.

$$?\ \text{L soln} = 0.00250\ \text{mol } K_2CrO_4 \times \frac{1\ \text{L soln}}{0.250\ \text{mol } K_2CrO_4} = 0.0100\ \text{L soln}$$

An alternative approach is to use equation (4.5). The known factors include the volume of solution to be prepared, ($V_f = 250.0$ mL) and the concentrations of the final (0.0100 M) and initial (0.250 M) solutions. We must solve for the initial volume, V_i. Note that although in deriving equation (4.5) volumes were expressed in liters, in applying the equation any volume unit can be used as long as we use the same unit for both V_i and V_f (milliliters in the present case). The term needed to convert volumes to liters would appear on both sides of the equation and cancel out.

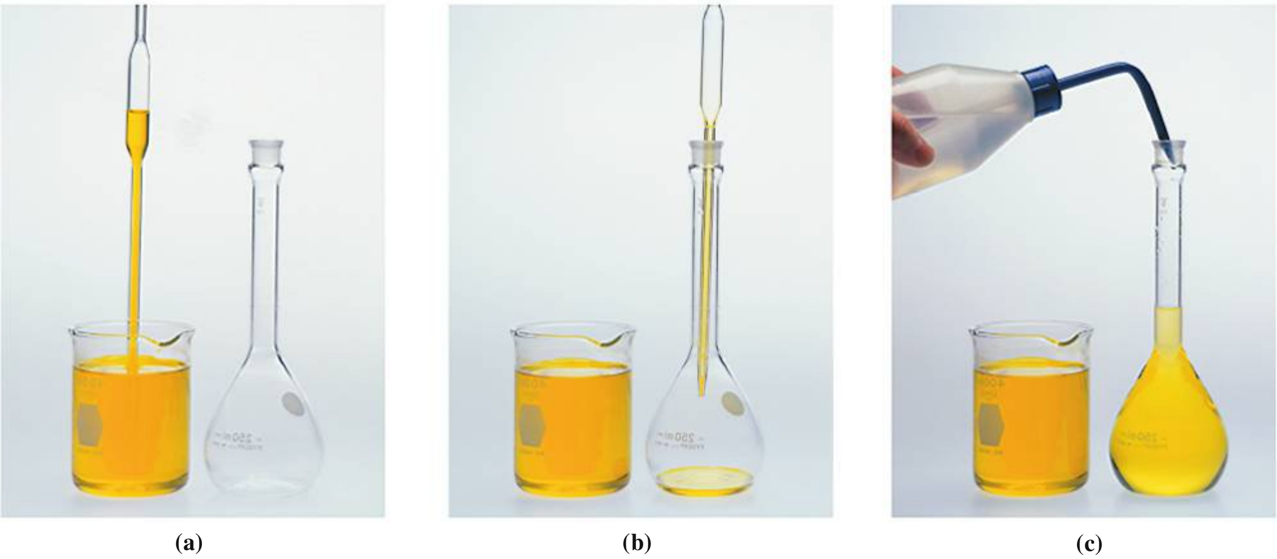
$$V_i = V_f \times \frac{M_f}{M_i} = 250.0\ \text{mL} \times \frac{0.0100\ \text{M}}{0.250\ \text{M}} = 10.0\ \text{mL}$$

Assess

Let's work the problem in reverse. If we dilute 10.0 mL of 0.250 M K_2CrO_4 to 0.250 L with water, then the concentration of the diluted solution is $0.010\ \text{L} \times 0.250\ \text{mol L}^{-1}/0.250\ \text{L} = 0.010\ \text{mol/L}$. This is the desired molarity; therefore, the answer, 10.0 mL of 0.250 M K_2CrO_4, is correct.

PRACTICE EXAMPLE A: A 15.00 mL sample of 0.450 M K_2CrO_4 is diluted to 100.00 mL. What is the concentration of the new solution?

PRACTICE EXAMPLE B: When left in an open beaker for a period of time, the volume of 275 mL of 0.105 M NaCl is found to decrease to 237 mL because of the evaporation of water. What is the new concentration of the solution?



(a) (b) (c)

▲ FIGURE 4-7
Preparing a solution by dilution—Example 4-10 illustrated
(a) A pipet is used to withdraw a 10.0 mL sample of 0.250 M K_2CrO_4. **(b)** The pipetful of 0.250 M K_2CrO_4 is discharged into a 250.0 mL volumetric flask. **(c)** Water is then added to bring the level of the solution to the calibration mark on the neck of the flask. At this point, the solution is 0.0100 M K_2CrO_4.

4-4 CONCEPT ASSESSMENT

Without doing detailed calculations, and assuming that the volumes of solutions and water are additive, indicate the molarity of the final solution obtained as a result of

(a) adding 200.0 mL of water to 100.0 mL of 0.150 M NaCl
(b) evaporating 50.0 mL water from 250.0 mL of 0.800 M $C_{12}H_{22}O_{11}$
(c) mixing 150.0 mL 0.270 M KCl and 300.0 mL 0.135 M KCl

Stoichiometry of Reactions in Solution

The central conversion factor in Example 4-11 is the same as in previous stoichiometry problems—the appropriate stoichiometric factor. What differs from previous examples is that we use molarity as a conversion factor from solution volume to number of moles of reactant in a preliminary step preceding the stoichiometric factor.

We will consider a number of additional examples of stoichiometric calculations involving solutions in Chapter 5.

EXAMPLE 4-11 Relating the Mass of a Product to the Volume and Molarity of a Reactant Solution

A 25.00 mL pipetful of 0.250 M K_2CrO_4 is added to an excess of $AgNO_3(aq)$. What mass of Ag_2CrO_4 will precipitate from the solution?

$$K_2CrO_4(aq) + 2\,AgNO_3(aq) \longrightarrow Ag_2CrO_4(s) + 2\,KNO_3(aq)$$

Analyze

The fact that an excess of $AgNO_3(aq)$ is used tells us that all of the K_2CrO_4 in the 25.00 mL sample of $K_2CrO_4(aq)$ is consumed. The calculation begins with a volume of 25.00 mL and ends with a mass of Ag_2CrO_4 expressed in grams. The conversion pathway is mL soln $\longrightarrow$ L soln $\longrightarrow$ mol K_2CrO_4 $\longrightarrow$ mol Ag_2CrO_4 $\longrightarrow$ g Ag_2CrO_4.

Solve

Let's solve this problem by using a stepwise approach.

Convert the volume of $K_2CrO_4(aq)$ from milliliters to liters, and then use molarity as a conversion factor between volume of solution and moles of solute (as in Example 4-10).

$$? \text{ mol } K_2CrO_4 = 25.00 \text{ mL} \times \frac{1 \text{ L}}{1000 \text{ mL}} \times \frac{0.250 \text{ mol } K_2CrO_4}{1 \text{ L}}$$
$$= 6.25 \times 10^{-3} \text{ mol } K_2CrO_4$$

Use a stoichiometric factor from the equation to convert from moles of K_2CrO_4 to moles of Ag_2CrO_4.

$$? \text{ mol } Ag_2CrO_4 = 6.25 \times 10^{-3} \text{ mol } K_2CrO_4 \times \frac{1 \text{ mol } Ag_2CrO_4}{1 \text{ mol } K_2CrO_4}$$
$$= 6.25 \times 10^{-3} \text{ mol } Ag_2CrO_4$$

Use the molar mass to convert from moles to grams of Ag_2CrO_4.

$$? \text{ g } Ag_2CrO_4 = 6.25 \times 10^{-3} \text{ mol } Ag_2CrO_4 \times \frac{331.7 \text{ g } Ag_2CrO_4}{1 \text{ mol } Ag_2CrO_4}$$
$$= 2.07 \text{ g } Ag_2CrO_4$$

The same final answer can be obtained more directly by combining the steps into a single line calculation.

$$? \text{ g } Ag_2CrO_4 = 25.00 \text{ mL} \times \frac{1 \text{ L}}{1000 \text{ mL}} \times \frac{0.250 \text{ mol } K_2CrO_4}{1 \text{ L}} \times \frac{1 \text{ mol } Ag_2CrO_4}{1 \text{ mol } K_2CrO_4} \times \frac{331.7 \text{ g } Ag_2CrO_4}{1 \text{ mol } Ag_2CrO_4}$$
$$= 2.07 \text{ g } Ag_2CrO_4$$

Assess

The units work out properly, which is always a good sign. As we have done before, let's work the problem in reverse and use numbers that are rounded off slightly. A 2 g sample of Ag_2CrO_4 contains $2/332 = 0.006$ moles of Ag_2CrO_4. The number of moles of K_2CrO_4 in the 25 mL sample of the K_2CrO_4 solution is also approximately 0.006 moles; thus, the molarity of the K_2CrO_4 solution is approximately $0.006 \text{ mol}/0.025 \text{ L} = 0.24$ M. This result is close to the true molarity (0.250 M), and so we can be confident that our answer for the mass of Ag_2CrO_4 is correct.

PRACTICE EXAMPLE A: How many milliliters of 0.250 M K_2CrO_4 must be added to excess $AgNO_3(aq)$ to produce 1.50 g Ag_2CrO_4?

[*Hint:* Think of this as the inverse of Example 4-11.]

PRACTICE EXAMPLE B: How many milliliters of 0.150 M $AgNO_3$ are required to react completely with 175 mL of 0.0855 M K_2CrO_4? What mass of Ag_2CrO_4 is formed?

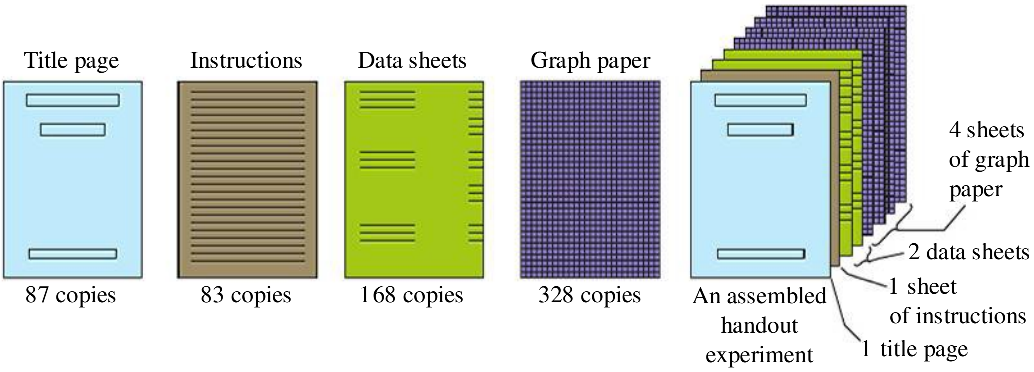
4-4 Determining the Limiting Reactant

When all the reactants are completely and simultaneously consumed in a chemical reaction, the reactants are said to be in **stoichiometric proportions**; that is, they are present in the mole ratios dictated by the coefficients in the balanced equation. This condition is sometimes required, for example, in certain chemical analyses. At other times, as in a precipitation reaction, one of the reactants is completely converted into products by using an excess of all the other reactants. The reactant that is completely consumed—the **limiting reactant**—determines the quantities of products formed. In the reaction described in Example 4-11, K_2CrO_4 is the limiting reactant and $AgNO_3$ is present in excess. Up to this point, we have stated which reactant is present in excess and, by implication, which is the limiting reactant. In some cases, however, the limiting reactant will not be indicated explicitly. If the quantities of two or more reactants are given, you must determine which is the limiting reactant, as suggested by the analogy in Figure 4-8.

Sometimes our interest in a limiting reactant problem is in determining how much of an excess reactant remains, as well as how much product is formed. This additional calculation is illustrated in Example 4-13.

◀ By an *excess of a reactant*, we mean that more of the reactant is present than is consumed in the reaction. Some is left over.

◀ Chemicals are often referred to as *reagents*, and the limiting reactant in a reaction is sometimes called the *limiting reagent*.



▲ FIGURE 4-8
An analogy to determining the limiting reactant in a chemical reaction—assembling a handout experiment
From the numbers of copies available and the instructions on how to assemble the handout, can you see that only 82 complete handouts are possible and that the graph paper is the limiting reactant?

EXAMPLE 4-12 Determining the Limiting Reactant in a Reaction

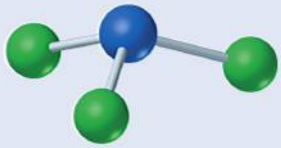
Phosphorus trichloride, PCl_3, is a commercially important compound used in the manufacture of pesticides, gasoline additives, and a number of other products. A ball-and-stick model of PCl_3 is shown in the margin. Liquid PCl_3 is made by the direct combination of phosphorus and chlorine.

$$P_4(s) + 6\,Cl_2(g) \longrightarrow 4\,PCl_3(l)$$

What is the maximum mass of PCl_3 that can be obtained from 125 g P_4 and 323 g Cl_2?

Analyze

The following conversions are required: mol limiting reactant → mol PCl_3 → g PCl_3. The key to solving this problem is to correctly identify the limiting reactant. One approach to this problem, outlined in Figure 4-9, is to compare the initial mole ratio of the two reactants with the ratio in which the reactants combine—6 mol Cl_2 to 1 mol P_4. If more than 6 mol Cl_2 is available per mole of P_4, chlorine is in excess and P_4 is the limiting reactant. If fewer than 6 mol Cl_2 is available per mole of P_4, chlorine is the limiting reactant.



Phosphorus trichloride

Grams of P_4
Grams of Cl_2
Use molar mass in the conversion factor: 1 mol P_4/123.9 g P_4
Use molar mass in the conversion factor: 1 mol Cl_2/70.91 g Cl_2
Moles of P_4
Moles of Cl_2
Calculate mole ratio of Cl_2 to P_4
Mole ratio = $\frac{\text{moles of } Cl_2}{\text{moles of } P_4}$
If calculated mole ratio < 6/1, Cl_2 is limiting
If calculated mole ratio > 6/1 P_4 is limiting

◀ FIGURE 4-9
Determining the limiting reactant for the reaction $P_4(s) + 6\ Cl_2(g) \longrightarrow 4\ PCl_3(l)$

Solve

$$? \text{ mol } Cl_2 = 323 \text{ g } Cl_2 \times \frac{1 \text{ mol } Cl_2}{70.91 \text{ g } Cl_2} = 4.56 \text{ mol } Cl_2$$

$$? \text{ mol } P_4 = 125 \text{ g } P_4 \times \frac{1 \text{ mol } P_4}{123.9 \text{ g } P_4} = 1.01 \text{ mol } P_4$$

Since there is less than 6 mol Cl_2 per mole of P_4, chlorine is the limiting reactant. The remainder of the calculation is to determine the mass of PCl_3 formed in the reaction of 323 g Cl_2 with an excess of P_4.

Having identified Cl_2 as the limiting reactant, we can complete the calculation as follows, using a stepwise approach.

Convert from grams of Cl_2 to moles of Cl_2 by using the molar mass of Cl_2.

$$? \text{ mol } Cl_2 = 323 \text{ g } Cl_2 \times \frac{1 \text{ mol } Cl_2}{70.91 \text{ g } Cl_2} = 4.56 \text{ mol } Cl_2$$

Convert from moles of Cl_2 to moles of PCl_3 by using the stoichiometric factor.

$$? \text{ mol } PCl_3 = 4.56 \text{ mol } Cl_2 \times \frac{4 \text{ mol } PCl_3}{6 \text{ mol } Cl_2} = 3.04 \text{ mol } PCl_3$$

Convert from moles of PCl_3 to grams of PCl_3 by using the molar mass of PCl_3.

$$? \text{ g } PCl_3 = 3.04 \text{ mol } PCl_3 \times \frac{137.3 \text{ g } PCl_3}{1 \text{ mol } PCl_3} = 417 \text{ g } PCl_3$$

Using the conversion pathway approach, we combine the steps into a single line calculation.

$$? \text{ g } PCl_3 = 323 \text{ g } Cl_2 \times \frac{1 \text{ mol } Cl_2}{70.91 \text{ g } Cl_2} \times \frac{4 \text{ mol } PCl_3}{6 \text{ mol } Cl_2} \times \frac{137.3 \text{ g } PCl_3}{1 \text{ mol } PCl_3} = 417 \text{ g } PCl_3$$

Assess

A different approach that leads to the same result is to do two separate calculations. First, calculate the mass of PCl_3 produced by the reaction of 323 g Cl_2 with an excess of P_4 (= 417 g PCl_3), and then calculate the mass of PCl_3 produced by the reaction of 125 g P_4 with an excess of Cl_2 (= 554 g PCl_3). Only one answer can be correct, and it must be the *smaller* of the two. An advantage of this approach is that it can be easily generalized to deal with reactions involving many reactants.

PRACTICE EXAMPLE A: If 215 g P_4 is allowed to react with 725 g Cl_2 in the reaction in Example 4-12, how many grams of PCl_3 are formed?

PRACTICE EXAMPLE B: If 1.00 kg each of PCl_3, Cl_2, and P_4O_{10} are allowed to react, how many kilograms of $POCl_3$ will be formed?

$$6\ PCl_3(l) + 6\ Cl_2(g) + P_4O_{10}(s) \longrightarrow 10\ POCl_3(l)$$

EXAMPLE 4-13 Determining the Quantity of Excess Reactant(s) Remaining After a Reaction

What mass of P_4 remains following the reaction in Example 4-12?

Analyze

We established in Example 4-12 that Cl_2 is the limiting reactant and P_4 is the excess reactant. The key to this problem is to calculate the mass of P_4 that is consumed, and we can base this calculation either on the mass of Cl_2 consumed or on the mass of PCl_3 produced. Starting from the mass of Cl_2 consumed, we use the following conversion pathway to calculate the mass of P_4 that is consumed.

$$\text{g Cl}_2 \longrightarrow \text{mol Cl}_2 \longrightarrow \text{mol P}_4 \longrightarrow \text{g P}_4$$

The mass of P_4 that remains is calculated by subtracting the mass of P_4 that is consumed from the total mass of P_4.

Solve

We can calculate the mass of P_4 that is consumed by using the following stepwise approach.

Convert from grams of Cl_2 to moles of Cl_2 by using the molar mass of Cl_2.

$$? \text{ mol Cl}_2 = 323 \text{ g Cl}_2 \times \frac{1 \text{ mol Cl}_2}{70.91 \text{ g Cl}_2} = 4.56 \text{ mol Cl}_2$$

Convert from moles of Cl_2 to moles of P_4 by using the stoichiometric factor.

$$? \text{ mol P}_4 = 4.56 \text{ mol Cl}_2 \times \frac{1 \text{ mol P}_4}{6 \text{ mol Cl}_2} = 0.759 \text{ mol P}_4$$

Convert from moles of P_4 to grams of P_4 by using the molar mass of P_4.

$$? \text{ g P}_4 = 0.759 \text{ mol P}_4 \times \frac{123.9 \text{ g P}_4}{1 \text{ mol P}_4} = 94.1 \text{ g P}_4$$

The single line calculation is as follows.

$$? \text{ g P}_4 = 323 \text{ g Cl}_2 \times \frac{1 \text{ mol Cl}_2}{70.91 \text{ g Cl}_2} \times \frac{1 \text{ mol P}_4}{6 \text{ mol Cl}_2} \times \frac{123.9 \text{ g P}_4}{1 \text{ mol P}_4} = 94.1 \text{ g P}_4$$

The following single line calculation shows that we obtain the same answer starting from the mass of PCl_3 that is produced.

$$? \text{ g P}_4 = 417 \text{ g PCl}_3 \times \frac{1 \text{ mol PCl}_3}{137.3 \text{ g PCl}_3} \times \frac{1 \text{ mol P}_4}{4 \text{ mol PCl}_3} \times \frac{123.9 \text{ g P}_4}{1 \text{ mol P}_4} = 94.1 \text{ g P}_4$$

The mass of P_4 remaining after the reaction is simply the difference between what was originally present and what was consumed; that is,

$$125 \text{ g P}_4 \text{ initially} - 94.1 \text{ g P}_4 \text{ consumed} = 31 \text{ g P}_4 \text{ remaining}$$

Assess

It is possible to use the law of conservation of mass to verify that the calculated result is correct. The total mass of the reactants used in the reaction ($323 \text{ g} + 125 \text{ g} = 448 \text{ g}$) must be equal to the mass of product (417 g) plus the mass of the P_4 that remains. Therefore, the mass of the P_4 that remains is $448 \text{ g} - 417 \text{ g} = 31 \text{ g}$. In performing the subtraction required in this example, the quantity with the fewest digits after the decimal point determines how the answer should be expressed. Because there are no digits after the decimal point in 125, there can be none after the decimal point in 31.

PRACTICE EXAMPLE A: In Practice Example 4-12A, which reactant is in excess and what mass of that reactant remains after the reaction to produce PCl_3?

PRACTICE EXAMPLE B: If 12.2 g H_2 and 154 g O_2 are allowed to react, which gas and what mass of that gas remains after the reaction?

$$2 \text{ H}_2(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2 \text{ H}_2\text{O(l)}$$

4-5 CONCEPT ASSESSMENT

Suppose that the reaction of 1.0 mol NH_3(g) and 1.0 mol O_2(g) is carried to completion, producing NO(g) and H_2O(l) as the only products. Which, if any, of the following statements is correct about this reaction? **(a)** 1.0 mol NO(g) is produced; **(b)** 4.0 mol NO(g) is produced; **(c)** 1.5 mol H_2O(l) is produced; **(d)** all the O_2(g) is consumed; **(e)** NH_3(g) is the limiting reactant.

4-5 Other Practical Matters in Reaction Stoichiometry

In this section we consider a few additional factors in reaction stoichiometry—both in the laboratory and in the manufacturing plant. First, the calculated outcome of a reaction may not be what is actually observed. Specifically, the amount of product may be, unavoidably, less than expected. Second, the route to producing a desired chemical may require several reactions carried out in sequence. And third, in some cases two or more reactions may occur simultaneously.

Theoretical Yield, Actual Yield, and Percent Yield

The **theoretical yield** of a reaction is the calculated quantity of product expected from given quantities of reactants. The quantity of product that is actually produced is called the **actual yield**. The **percent yield** is defined as

$$\text{percent yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\% \qquad \textbf{(4.6)}$$

In many reactions the actual yield almost exactly equals the theoretical yield, and the reactions are said to be *quantitative*. Such reactions can be used in quantitative chemical analyses. In other reactions the actual yield is less than the theoretical yield, and the percent yield is less than 100%. The reduced yield may occur for a variety of reasons. (1) The product of a reaction rarely appears in a pure form, and some product may be lost during the necessary purification steps, which reduces the yield. (2) In many cases the reactants may participate in reactions other than the one of central interest. These are called **side reactions**, and the unintended products are called **by-products**. To the extent that side reactions occur, the yield of the main product is reduced. (3) If a reverse reaction occurs, some of the expected product may react to re-form the reactants, and again the yield is less than expected.

At times, the apparent yield is greater than 100%. Because we cannot get something from nothing, this situation usually indicates an error in technique. Some products are formed as a precipitate from a solvent. If the product is weighed when it is wet with solvent, the result will be a larger-than-expected mass. More thorough drying of the product would give a more accurate yield determination. Another possibility is that the product is contaminated with an excess reactant or a by-product. This makes the mass of product appear larger than expected. In any case, a product must be purified before its yield is determined.

In Example 4-14, we establish the theoretical, actual, and percent yields of an important industrial process.

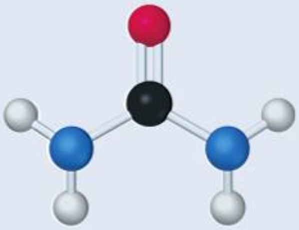
If we know that a yield will be less than 100%, we need to adjust the amounts of reactants used to produce the desired amount of product. We cannot simply use the theoretical amounts of reactants; we must use more. This point is illustrated in Example 4-15.

Consecutive, Simultaneous, and Overall Reactions

Both in laboratory work and in manufacturing, the preferred processes are those that yield a product through a single reaction. Often such processes give a higher yield because there is no need to remove products from one reaction mixture for further processing in subsequent reactions. However, in many cases a multistep process is unavoidable. **Consecutive reactions** are reactions carried out one after another in sequence to yield a final product. In **simultaneous reactions**, two or

EXAMPLE 4-14 Determining Theoretical, Actual, and Percent Yields

Billions of kilograms of urea, $CO(NH_2)_2$, are produced annually for use as a fertilizer. A ball-and-stick model of urea is shown here. The reaction used is given below.



Urea

$$2\ NH_3(g) + CO_2(g) \longrightarrow CO(NH_2)_2(s) + H_2O(l)$$

The typical starting reaction mixture has a 3:1 mole ratio of NH_3 to CO_2. If 47.7 g urea forms *per mole* of CO_2 that reacts, what is the **(a)** theoretical yield; **(b)** actual yield; and **(c)** percent yield?

Analyze

The reaction mixture contains fixed amounts of NH_3 and CO_2, and so we must first determine which reactant is the limiting reactant. The stoichiometric proportions are 2 mol NH_3:1 mol CO_2. In the reaction mixture, the mole ratio of NH_3 to CO_2 is 3:1. Therefore, NH_3 is the excess reactant and CO_2 is the limiting reactant. The calculation of the theoretical yield of urea must be based on the amount of CO_2, the limiting reactant. Because the quantity of urea is given per mole of CO_2, we should base the calculation on 1.00 mol CO_2. The following conversions are required: mol $CO_2 \rightarrow$ mol $CO(NH_2)_2 \rightarrow$ g $CO(NH_2)_2$.

Solve

(a) Let's calculate the theoretical yield by using a stepwise approach.

Convert from mol CO_2 to mol $CO(NH_2)_2$ by using the stoichiometric factor.

$$?\ \text{mol } CO(NH_2)_2 = 1.00\ \text{mol } CO_2 \times \frac{1\ \text{mol } CO(NH_2)_2}{1\ \text{mol } CO_2}$$
$$= 1.00\ \text{mol } CO(NH_2)_2$$

Convert from mol $CO(NH_2)_2$ to g $CO(NH_2)_2$ by using the molar mass of $CO(NH_2)_2$.

$$?\ \text{g } CO(NH_2)_2 = 1.00\ \text{mol } CO(NH_2)_2 \times \frac{60.1\ \text{g } CO(NH_2)_2}{1\ \text{mol } CO(NH_2)_2}$$
$$= 60.1\ \text{g } CO(NH_2)_2$$

Thus, 1.00 mol CO_2 is expected to yield 60.1 g $CO(NH_2)_2$, and so the theoretical yield of $CO(NH_2)_2$ is 60.1 g. As has been the case in all our examples, we could have combined the steps into a single line calculation.

$$\text{theoretical yield} = 1.00\ \text{mol } CO_2 \times \frac{1\ \text{mol } CO(NH_2)_2}{1\ \text{mol } CO_2} \times \frac{60.1\ \text{g } CO(NH_2)_2}{1\ \text{mol } CO(NH_2)_2} = 60.1\ \text{g } CO(NH_2)_2$$

(b) $\text{actual yield} = 47.7\ \text{g } CO(NH_2)_2$

(c) $\text{percent yield} = \dfrac{47.7\ \text{g } CO(NH_2)_2}{60.1\ \text{g } CO(NH_2)_2} \times 100\% = 79.4\%$

Assess

A quick way to determine the limiting reactant is to identify the reactant that has the smallest value of $(n/coeff)$, where n is the number of moles of reactant available and $coeff$ is the coefficient of that reactant in the balanced chemical equation. In this example, the reaction mixture contains 3 mol NH_3 and 1 mol CO_2, and so $(n/coeff)$ is $3/2 = 1.5$ for NH_3 and $1/1 = 1$ for CO_2. Because $1 < 1.5$, CO_2 is the limiting reactant. To understand why we can identify the limiting reactant by using this method, it is helpful to consider how we convert from moles of reactant to moles of product: $n\ \text{mol reactant} \times \dfrac{\text{coefficient of product}}{\text{coefficient of reactant}}$. The smaller the value of $(n/coeff)$, the smaller the amount of product. The limiting reactant is the one that yields the smallest amount of product (as explained in Example 4-12); thus, the limiting reactant is the one with the smallest value of $(n/coeff)$

PRACTICE EXAMPLE A: Formaldehyde, CH_2O, can be made from methanol by the following reaction, using a copper catalyst.

$$CH_3OH(g) \longrightarrow CH_2O(g) + H_2(g)$$

If 25.7 g $CH_2O(g)$ is produced per mole of methanol that reacts, what are **(a)** the theoretical yield, **(b)** the actual yield, and **(c)** the percent yield?

PRACTICE EXAMPLE B: What is the percent yield if the reaction of 25.0 g P_4 and 91.5 g Cl_2 produces 104 g PCl_3? The balanced chemical equation for the reaction is given below.

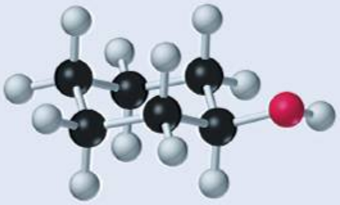
$$P_4(s) + 6\ Cl_2(g) \longrightarrow 4\ PCl_3(l)$$

EXAMPLE 4-15 Adjusting the Quantities of Reactants in Accordance with the Percent Yield of a Reaction

When heated with sulfuric or phosphoric acid, cyclohexanol, $C_6H_{11}OH$, is converted to cyclohexene, C_6H_{10}. Ball-and-stick models of cyclohexanol and cyclohexene are shown here. The balanced chemical equation for the reaction is shown below.

$$C_6H_{11}OH(l) \longrightarrow C_6H_{10}(l) + H_2O(l) \qquad (4.7)$$

If the percent yield is 83%, what mass of cyclohexanol must we use to obtain 25 g of cyclohexene?



Cyclohexanol

Cyclohexene

Analyze

We are given the percent yield (83%) and the actual yield of C_6H_{10} (25 g). We can use equation (4.6) to calculate the theoretical yield of C_6H_{10}. Then, we can calculate the quantity of $C_6H_{11}OH$ required to produce the theoretical yield of C_6H_{10} by using the following series of conversions: $g\ C_6H_{10} \rightarrow mol\ C_6H_{10} \rightarrow mol\ C_6H_{11}OH \rightarrow g\ C_6H_{11}OH$.

Solve

Let's use a stepwise approach.

Rearrange equation (4.6) and calculate the theoretical yield.

$$\text{theoretical yield} = \frac{25\text{ g} \times 100\%}{83\%} = 3.0 \times 10^1\text{ g}$$

The theoretical yield is expressed as 3.0×10^1 g rather than as 30 g to emphasize that there are two significant figures in the calculated result. If we expressed the result as 30 g, then the number of significant figures would be ambiguous. (See Section 1-7.) The remaining conversions are as follows.

Convert from g C_6H_{10} to mol C_6H_{10} by using the molar mass of C_6H_{10}.

$$?\text{ mol } C_6H_{10} = 3.0 \times 10^1\text{ g } C_6H_{10} \times \frac{1\text{ mol } C_6H_{10}}{82.1\text{ g } C_6H_{10}} = 0.37\text{ mol } C_6H_{10}$$

Convert from mol C_6H_{10} to mol $C_6H_{11}OH$ using the stoichiometric factor.

$$?\text{ mol } C_6H_{11}OH = 0.37\text{ mol } C_6H_{10} \times \frac{1\text{ mol } C_6H_{11}OH}{1\text{ mol } C_6H_{10}} = 0.37\text{ mol } C_6H_{11}OH$$

Convert from mol $C_6H_{11}OH$ to g $C_6H_{11}OH$ by using the molar mass of $C_6H_{11}OH$.

$$?\text{ g } C_6H_{11}OH = 0.37\text{ mol } C_6H_{11}OH \times \frac{100.2\text{ g } C_6H_{11}OH}{1\text{ mol } C_6H_{11}OH} = 37\text{ g } C_6H_{11}OH$$

We could have combined the last three steps into a single line calculation. The single line calculation is shown below, starting from a theoretical yield of 3.0×10^1 g C_6H_{10}.

$$?\text{ g } C_6H_{11}OH = 30\text{ g } C_6H_{10} \times \frac{1\text{ mol } C_6H_{10}}{82.1\text{ g } C_6H_{10}} \times \frac{1\text{ mol } C_6H_{11}OH}{1\text{ mol } C_6H_{10}} \times \frac{100.2\text{ g } C_6H_{11}OH}{1\text{ mol } C_6H_{11}OH} = 37\text{ g } C_6H_{11}OH$$

Assess

Because we have already calculated the molar masses of C_6H_{10} and $C_6H_{11}OH$, it is a simple matter to work the problem in reverse by using numbers that are slightly rounded off. A 37 g sample of $C_6H_{11}OH$ contains approximately $37/100 = 0.37$ moles of $C_6H_{11}OH$, and we expect a maximum of 0.37 moles of C_6H_{10} or $0.37 \times 82 \approx 30$ g C_6H_{10}. We obtain only 25 g C_6H_{10} and so the percent yield for the experiment is approximately $(25/30) \times 100\% = 83\%$. By working the problem in reverse, we verify that the percent yield is 83%; thus, we are confident we have solved the problem correctly.

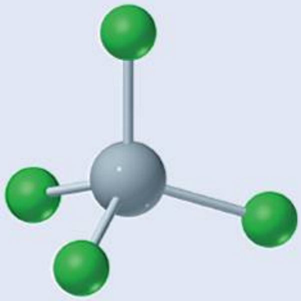
PRACTICE EXAMPLE A: If the percent yield for the formation of urea in Example 4-14 were 87.5%, what mass of CO_2, together with an excess of NH_3, would have to be used to obtain 50.0 g $CO(NH_2)_2$?

PRACTICE EXAMPLE B: Calculate the mass of cyclohexanol ($C_6H_{11}OH$) needed to produce 45.0 g cyclohexene (C_6H_{10}) by reaction (4.7) if the reaction has a 86.2% yield and the cyclohexanol is 92.3% pure.

more substances react independently of one another in separate reactions occurring at the same time.

Example 4-16 presents an industrial process that is carried out in two consecutive reactions. The key to the calculation is to use a stoichiometric factor for each reaction. Example 4-17 deals with two reactions that occur simultaneously to produce a common product, hydrogen gas.

EXAMPLE 4-16 Calculating the Quantity of a Substance Produced by Reactions Occurring Consecutively



Titanium tetrachloride

Titanium dioxide, TiO_2, is the most widely used white pigment for paints, having displaced most lead-based pigments, which are environmental hazards. Before it can be used, however, naturally occurring TiO_2 must be freed of colored impurities. One process for doing this converts impure $TiO_2(s)$ to $TiCl_4(g)$, which is then converted back to pure $TiO_2(s)$. The process is based on the following reactions, the first of which generates $TiCl_4$.

$$2\ TiO_2\,(\text{impure}) + 3\ C(s) + 4\ Cl_2(g) \longrightarrow 2\ TiCl_4(g) + CO_2(g) + 2\ CO(g)$$
$$TiCl_4(g) + O_2(g) \longrightarrow TiO_2(s) + 2\ Cl_2(g)$$

What mass of carbon is consumed in producing 1.00 kg of pure $TiO_2(s)$ in this process?

Analyze

In this calculation, we begin with the product, TiO_2, and work backward to one of the reactants, C. The following conversions are required.

$$\text{kg } TiO_2 \longrightarrow \text{g } TiO_2 \longrightarrow \text{mol } TiO_2 \xrightarrow{(a)} \text{mol } TiCl_4 \xrightarrow{(b)} \text{mol C} \longrightarrow \text{g C}$$

In the conversion from mol TiO_2 to mol $TiCl_4$, labeled (a), we focus on the second reaction. In the conversion from mol $TiCl_4$ to mol C, labeled (b), we focus on the first reaction.

Solve

Using a stepwise approach, we proceed as follows.

Convert from kg TiO_2 to g TiO_2 and then to mol TiO_2 by using the molar mass of TiO_2.

$$?\ \text{mol } TiO_2 = 1.00\ \text{kg } TiO_2 \times \frac{1000\ \text{g } TiO_2}{1\ \text{kg } TiO_2} \times \frac{1\ \text{mol } TiO_2}{79.88\ \text{g } TiO_2} = 12.5\ \text{mol } TiO_2$$

Convert from mol TiO_2 to mol $TiCl_4$ by using the stoichiometric factor from the second reaction.

$$?\ \text{mol } TiCl_4 = 12.5\ \text{mol } TiO_2 \times \underbrace{\frac{1\ \text{mol } TiCl_4}{1\ \text{mol } TiO_2}}_{(a)} = 12.5\ \text{mol } TiCl_4$$

Convert from mol $TiCl_4$ to mol C by using the stoichiometric factor from the first reaction.

$$?\ \text{mol C} = 12.5\ \text{mol } TiCl_4 \times \underbrace{\frac{3\ \text{mol C}}{2\ \text{mol } TiCl_4}}_{(b)} = 18.8\ \text{mol C}$$

Convert from mol C to g C by using the molar mass of C.

$$?\ \text{g C} = 18.8\ \text{mol C} \times \frac{12.01\ \text{g C}}{1\ \text{mol C}} = 226\ \text{g C}$$

The conversions given above can be combined into a single line, as shown below.

$$?\ \text{g C} = 1.00\ \text{kg } TiO_2 \times \frac{1000\ \text{g } TiO_2}{1\ \text{kg } TiO_2} \times \frac{1\ \text{mol } TiO_2}{79.88\ \text{g } TiO_2} \times \overset{(a)}{\frac{1\ \text{mol } TiCl_4}{1\ \text{mol } TiO_2}} \times \overset{(b)}{\frac{3\ \text{mol C}}{2\ \text{mol } TiCl_4}} \times \frac{12.01\ \text{g C}}{1\ \text{mol C}} = 226\ \text{g C}$$

Assess

To obtain the stoichiometric factor for converting from mol TiO_2 to mol C, we could have reasoned as follows. From the equations for the two reactions, we see that 3 mol C will give 2 mol $TiCl_4$, which then reacts to give an equal amount (2 mol) of TiO_2. That is, 3 mol C will give 2 mol TiO_2, or equivalently, 2 mol TiO_2 requires 3 mol C. Thus, the required stoichiometric factor is (3 mol C)/(2 mol TiO_2), the product of the two factors above labeled (a) and (b).

(continued)

PRACTICE EXAMPLE A: Nitric acid, HNO_3, is produced from ammonia and oxygen by the consecutive reactions

$$\begin{aligned} 4\,NH_3(g) + 5\,O_2(g) &\longrightarrow 4\,NO(g) + 6\,H_2O(g) \\ 2\,NO(g) + O_2(g) &\longrightarrow 2\,NO_2(g) \\ 3\,NO_2(g) + H_2O(l) &\longrightarrow 2\,HNO_3(aq) + NO(g) \end{aligned}$$

How many grams of nitric acid can be obtained from 1.00 kg $NH_3(g)$, if NO(g) in the third reaction is *not* recycled?

PRACTICE EXAMPLE B: Nitrogen gas is used to inflate automobile airbags. The gas is produced by detonation of a pellet containing NaN_3, KNO_3, and SiO_2 (all solids). When detonated, NaN_3 decomposes into $N_2(g)$ and Na(l). The Na(l) reacts almost instantly with KNO_3 producing more $N_2(g)$ as well as K_2O and Na_2O. The K_2O and Na_2O are each converted independently into harmless salts, Na_2SiO_3 and K_2SiO_3, when they react with SiO_2. Balanced chemical equations for the reactions are given below.

$$\begin{aligned} 2\,NaN_3(s) &\longrightarrow 3\,N_2(g) + 2\,Na(l) \\ 10\,Na(l) + 2\,KNO_3(s) &\longrightarrow N_2(s) + K_2O(s) + 5\,Na_2O(s) \\ K_2O(s) + SiO_2(s) &\longrightarrow K_2SiO_3(s) \\ Na_2O(s) + SiO_2(s) &\longrightarrow Na_2SiO_3(s) \end{aligned}$$

What are the minimum masses of KNO_3 and SiO_2 that must be mixed with 95 g NaN_3 to ensure that no Na, Na_2O, or K_2O remains after the mixture is detonated?

EXAMPLE 4-17 Calculating the Quantity of a Substance Produced by Reactions Occurring Simultaneously

Magnesium–aluminum alloys are widely used in aircraft construction. One particular alloy contains 70.0% Al and 30.0% Mg, by mass. How many grams of $H_2(g)$ are produced in the reaction of a 0.710 g sample of this alloy with excess HCl(aq)? Balanced chemical equations are given below for the reactions that occur.

$$\begin{aligned} 2\,Al(s) + 6\,HCl(aq) &\longrightarrow 2\,AlCl_3(aq) + 3\,H_2(g) \\ Mg(s) + 2\,HCl(aq) &\longrightarrow MgCl_2(aq) + H_2(g) \end{aligned}$$

Analyze

The two reactions given above are simultaneous reactions. Simultaneous reactions occur independently; thus, we have two conversion pathways to consider:

(1) $\text{g alloy} \longrightarrow \text{g Al} \longrightarrow \text{mol Al} \xrightarrow{(a)} \text{mol } H_2;$

(2) $\text{g alloy} \longrightarrow \text{g Mg} \longrightarrow \text{mol Mg} \xrightarrow{(b)} \text{mol } H_2;$

Pathways (1) and (2) are based on the first and second reactions, respectively. The total amount of H_2 produced is obtained by adding together the amounts produced by each reaction. The conversion from mol Al to mol H_2 requires a stoichiometric factor, labeled (a). The conversion from mol Mg to mol H_2 requires a different stoichiometric factor, labeled (b).

Solve

Convert from g alloy to mol Al and from g alloy to mol Mg by using the mass percentages of Al and Mg and the molar masses of Al and Mg.

$$\begin{aligned} ?\ \text{mol Al} &= 0.710\ \text{g alloy} \times \frac{70.0\ \text{g Al}}{100.0\ \text{g alloy}} \times \frac{1\ \text{mol Al}}{26.98\ \text{g Al}} \\ &= 0.0184\ \text{mol Al} \end{aligned}$$

$$\begin{aligned} ?\ \text{mol Mg} &= 0.710\ \text{g alloy} \times \frac{30.0\ \text{g Mg}}{100.0\ \text{g alloy}} \times \frac{1\ \text{mol Mg}}{24.31\ \text{g Mg}} \\ &= 8.76 \times 10^{-3}\ \text{mol Mg} \end{aligned}$$

Convert from mol Al to mol H_2 and from mol Mg to mol H_2 by using stoichiometric factors (a) and (b). The total number of moles of H_2 is obtained by adding together the two independent contributions.

$$? \text{ mol } H_2 = 0.0184 \text{ mol Al} \times \underbrace{\frac{3 \text{ mol } H_2}{2 \text{ mol Al}}}_{(a)} +$$

$$8.76 \times 10^{-3} \text{ mol Mg} \times \underbrace{\frac{1 \text{ mol } H_2}{1 \text{ mol Mg}}}_{(b)} = 0.0364 \text{ mol } H_2$$

Convert from mol H_2 to g H_2 by using the molar mass of H_2 as a conversion factor.

$$? \text{ g } H_2 = 0.0364 \text{ mol } H_2 \times \frac{2.016 \text{ g } H_2}{1 \text{ mol } H_2} = 0.0734 \text{ g } H_2$$

An alternative approach is to combine the steps into a single line calculation, as shown below.

$$? \text{ g } H_2 = \left(0.710 \text{ g alloy} \times \frac{70.0 \text{ g Al}}{100.0 \text{ g alloy}} \times \frac{1 \text{ mol Al}}{26.98 \text{ g Al}} \times \underbrace{\frac{3 \text{ mol } H_2}{2 \text{ mol Al}}}_{(a)} \times \frac{2.016 \text{ g } H_2}{1 \text{ mol } H_2}\right)$$

$$+ \left(0.710 \text{ g alloy} \times \frac{30.0 \text{ g Mg}}{100.0 \text{ g alloy}} \times \frac{1 \text{ mol Mg}}{24.31 \text{ g Mg}} \times \underbrace{\frac{1 \text{ mol } H_2}{1 \text{ mol Mg}}}_{(b)} \times \frac{2.016 \text{ g } H_2}{1 \text{ mol } H_2}\right) = 0.0734 \text{ g } H_2$$

Assess

In this example, the composition of the alloy is given and we solved for the amount of H_2 that is produced. The inverse problem, in which we are given the amount of H_2 produced and are asked to determine the amounts of Al and Mg in the alloy, is a little harder to solve. See Practice Examples A and B below.

PRACTICE EXAMPLE A: A 1.00 g sample of a magnesium-aluminum alloy yields 0.107 g H_2 when treated with an excess of HCl(aq). What is the percentage by mass of Al in the alloy? [*Hint:* This is the inverse of Example 4-17. To solve this problem, let m and $1.00 - m$ be the masses of Al and Mg, respectively, and then use these masses in the setup above to develop an equation that relates m to the total mass of H_2 obtained. Then solve for m.]

PRACTICE EXAMPLE B: A 1.500 g sample of a mixture containing only Cu_2O and CuO was treated with hydrogen to produce copper metal and water. After the water evaporated, 1.2244 g of pure copper metal was recovered. What is the percentage by mass of Cu_2O in the original mixture? Balanced chemical equations are given below for the reactions involved.

$$\text{CuO(s)} + \text{H}_2\text{(g)} \longrightarrow \text{Cu(s)} + \text{H}_2\text{O(l)}$$
$$\text{Cu}_2\text{O(s)} + \text{H}_2\text{(g)} \longrightarrow 2\,\text{Cu(s)} + \text{H}_2\text{O(l)}$$

4-6 CONCEPT ASSESSMENT

Suppose that each of these reactions has a 90% yield.

$$\text{CH}_4\text{(g)} + \text{Cl}_2\text{(g)} \longrightarrow \text{CH}_3\text{Cl(g)} + \text{HCl(g)}$$
$$\text{CH}_3\text{Cl(g)} + \text{Cl}_2\text{(g)} \longrightarrow \text{CH}_2\text{Cl}_2\text{(l)} + \text{HCl(g)}$$

Starting with 50.0 g CH_4 in the first reaction and an excess of Cl_2(g), the number of grams of CH_2Cl_2 formed in the second reaction is

(a) $50.0 \times 0.81 \times (85/16)$
(b) 50.0×0.90
(c) $50.0 \times 0.90 \times 0.90$
(d) $50.0 \times 0.90 \times 0.90 \times (16/50.5)(70.9/85)$

Often, we can combine a series of chemical equations for *consecutive reactions* to obtain a single equation to represent the overall reaction. The equation for this overall reaction is the **overall equation**. At times we can use the overall equation for solving problems instead of working with the individual equations. This strategy does not work, however, if the substance of interest is not a starting material or final product but appears only in one of the intermediate reactions. Any substance that is produced in one step and consumed in another step of a multistep process is called an **intermediate**. In Example 4-16, $TiCl_4(g)$ is an intermediate.

To write an overall equation for Example 4-16, multiply the coefficients in the second equation by the factor 2, add the second equation to the first, and cancel any substances that appear on both sides of the overall equation.

$$\begin{array}{rl} 2\,\cancel{TiO_2}\text{ (impure)} + 3\,C(s) + 4\,\cancel{Cl_2}(g) & \longrightarrow 2\,\cancel{TiCl_4}(g) + CO_2(g) + 2\,CO(g) \\ 2\,\cancel{TiCl_4}(g) + 2\,O_2(g) & \longrightarrow 2\,\cancel{TiO_2}(s) + 4\,\cancel{Cl_2}(g) \\ \hline \textit{Overall equation:}\quad 3\,C(s) + 2\,O_2(g) & \longrightarrow CO_2(g) + 2\,CO(g) \end{array}$$

The result suggests that (1) we should obtain as much TiO_2 in the second reaction as we started with in the first, (2) the $Cl_2(g)$ produced in the second reaction can be recycled back into the first reaction, and (3) the only substances actually consumed in the overall reaction are C(s) and $O_2(g)$. You can also see that we could not have used this overall equation in the calculation of Example 4-16—$TiO_2(s)$ does not appear in it.

▶Whereas chemical equations for consecutive reactions can be combined to obtain an equation for the overall reaction, those for a set of simultaneous reactions cannot. If the two equations from Example 4-17 were added, we would obtain the equation $2\,Al + Mg + 8\,HCl \rightarrow 2\,AlCl_3 + MgCl_2 + 4\,H_2$. This equation is clearly incorrect because, for example, it suggests that to make H_2, the reaction mixture must contain both Al and Mg. However, we know that each metal can react independently with HCl to give H_2.

MasteringCHEMISTRY **www.masteringchemistry.com.**

Every day, tons of chemicals are made to be used directly or as reactants in the production of other materials. Because these chemicals are sold for use in everything from food to pharmaceuticals, it is important that they made in high yield and be of high purity. To learn more about the many factors that chemists and engineers must consider when making decisions about building and operating a chemical plant, go to the Focus On feature for Chapter 4, Industrial Chemistry, on the MasteringChemistry site.

Summary

4-1 Chemical Reactions and Chemical Equations—**Chemical reactions** are processes in which one or more starting substances, the **reactants**, form one or more new substances, the **products**. A chemical reaction can be represented symbolically in a **chemical equation**, with formulas of reactants on the left and formulas of products on the right; reactants and products are separated by an arrow. The equation must be balanced. A **balanced equation** reflects the true quantitative relationships between reactants and products. An equation is balanced by placing **stoichiometric coefficients** before formulas to signify that the total number of each kind of atom is the same on each side of the equation. The physical states of reactants and products can be indicated by symbols, such as (s), (l), (g), and (aq), signifying solid, liquid, gas, and aqueous solution, respectively.

4-2 Chemical Equations and Stoichiometry—**Stoichiometry** comprises quantitative relationships based on atomic and molecular masses, chemical formulas, balanced chemical equations, and related matters. The stoichiometry of chemical reactions makes use of conversion factors derived from balanced chemical equations and called **stoichiometric factors** (Fig. 4-3). Stoichiometric calculations usually require molar masses, densities, percent compositions, along with other factors.

4-3 Chemical Reactions in Solution—The **molarity** of a solution is the amount of **solute** (in moles) per liter of solution (expression 4.3). Molarity can be treated as a conversion factor between solution volume and amount of solute. Molarity as a conversion factor may be applied to individual solutions, to solutions that are mixed or diluted by adding more **solvent** (Fig. 4-6; expression 4.5), and to reactions occurring in solution.

4-4 Determining the Limiting Reactant—In some reactions, one of the reactants is completely consumed, while the other reactants remain in excess. The reactant that is completely consumed determines the amount of product formed and is called the **limiting reactant**. In some reactions, the reactants are consumed simultaneously, with no reactant remaining in excess; such reactants are said to be in **stoichiometric proportions**. In some reactions, the limiting reactant must be determined before a stoichiometric calculation can be completed.

4-5 Other Practical Matters in Reaction Stoichiometry—Stoichiometric calculations sometimes involve additional factors, including the reaction's **actual yield**, the presence of **by-products**, and how the reaction or reactions proceed. For example, some reactions yield exactly the quantity of product calculated—the **theoretical yield**. When the actual yield equals the theoretical yield, the **percent yield** is 100%. In some reactions, the actual yield is less than the theoretical, in which case the percent yield is less than 100%. Lower yields may result from the formation of by-products, substances that replace some of the desired product because of reactions other than the one of interest, called **side reactions**. Some stoichiometric calculations are complicated by the fact that two or more **simultaneous reactions** may occur. In other cases, a final product may be formed through a sequence of **consecutive reactions**. An **intermediate** is any substance that is a product of one reaction and a reactant in a subsequent reaction. The equations for a series of consecutive reactions are often replaced with a single **overall equation** for the **overall reaction**.

Integrative Example

Sodium nitrite is used in the production of dyes for coloring fabrics, as a preservative in meat processing (to prevent botulism), as a bleach for fibers, and in photography. It can be prepared by passing nitrogen monoxide and oxygen gases into an aqueous solution of sodium carbonate. Carbon dioxide gas is another product of the reaction.

In one experimental method, which gives a 95.0% yield, 225 mL of 1.50 M aqueous solution of sodium carbonate, 22.1 g of nitrogen monoxide, and a large excess of oxygen gas are allowed to react. What mass of sodium nitrite is obtained?

Analyze

Five tasks must be performed in this problem: (1) Represent the reaction by a chemical equation in which the names of reactants and products are replaced with formulas. (2) Balance the formula equation by inspection. (3) Determine the limiting reactant. (4) Calculate the theoretical yield of sodium nitrite based on the quantity of limiting reactant. (5) Use expression (4.6) to calculate the actual yield of sodium nitrite.

Solve

Obtain the unbalanced equation: Substitute formulas for names.

$$\mathrm{Na_2CO_3(aq) + NO(g) + O_2(g) \longrightarrow NaNO_2(aq) + CO(g)}$$

Obtain the balanced equation: Begin by noting that there must be 2 $NaNO_2$ for every Na_2CO_3.

$$\mathrm{Na_2CO_3(aq) + NO(g) + O_2(g) \longrightarrow 2\,NaNO_2(aq) + CO_2(g)}$$

To balance the N atoms requires 2 NO on the left side:

$$\mathrm{Na_2CO_3(aq) + 2\,NO(g) + O_2(g) \longrightarrow 2\,NaNO_2(aq) + CO_2(g)}$$

To balance the O atoms requires $\frac{1}{2}$ O_2 on the left, resulting in six O atoms on each side:

$$\mathrm{Na_2CO_3(aq) + 2\,NO(g) + \frac{1}{2}O_2(g) \longrightarrow 2\,NaNO_2(aq) + CO_2(g)}$$

Multiply coefficients by 2 to make all of them integers in the final balanced equation.

$$\mathrm{2\,Na_2CO_3(aq) + 4\,NO(g) + O_2(g) \longrightarrow 4\,NaNO_2(aq) + 2\,CO_2(g)}$$

Determine the limiting reactant: The problem states that oxygen is in excess. To determine the limiting reactant, the number of moles of Na_2CO_3, requiring molarity as a conversion factor, must be compared with the number of moles of NO, requiring a conversion factor based on the molar mass of NO.

$$? \text{ mol } \mathrm{Na_2CO_3} = 0.225 \text{ L soln} \times \frac{1.50 \text{ mol } \mathrm{Na_2CO_3}}{1 \text{ L soln}}$$
$$= 0.338 \text{ mol } \mathrm{Na_2CO_3}$$

$$? \text{ mol NO} = 22.1 \text{ g NO} \times \frac{1 \text{ mol NO}}{30.01 \text{ g NO}} = 0.736 \text{ mol NO}$$

From the balanced equation, the stoichiometric mole ratio is

$$4 \text{ mol NO} : 2 \text{ mol } \mathrm{Na_2CO_3} = 2:1$$

The available mole ratio is

$$0.736 \text{ mol NO} : 0.338 \text{ mol } \mathrm{Na_2CO_3} = 2.18:1$$

Because the available mole ratio exceeds 2:1, NO is in excess and Na_2CO_3 is the limiting reactant.

Determine the theoretical yield of the reaction: This calculation is based on the amount of Na_2CO_3, the limiting reactant.

$$? \text{ g } \mathrm{NaNO_2} = 0.338 \text{ mol } \mathrm{Na_2CO_3} \times \frac{4 \text{ mol } \mathrm{NaNO_2}}{2 \text{ mol } \mathrm{Na_2CO_3}}$$
$$\times \frac{69.00 \text{ g } \mathrm{NaNO_2}}{1 \text{ mol } \mathrm{NaNO_2}} = 46.6 \text{ g } \mathrm{NaNO_2}$$

Determine the actual yield: Use expression (4.6), which relates percent yield (95.0%), theoretical yield (46.6 g $NaNO_2$), and the actual yield.

$$\text{actual yield} = \frac{\text{percent yield} \times \text{theoretical yield}}{100\%}$$
$$= \frac{95.0\% \times 46.6 \text{ g } \mathrm{NaNO_2}}{100\%} = 44.3 \text{ g } \mathrm{NaNO_2}$$

Assess

After solving a multistep problem, it is important to check over your work. In this example, we should first double-check that the chemical equation is properly balanced. There are 4 Na's on each side, 2 C's, 12 O's, and 4 N's. We can double-check that we correctly identified the limiting reagent by using a different approach. Because 0.338 mol Na_2CO_3 would yield 0.676 mol $NaNO_2$ (in the presence of excess NO and O_2) and 0.736 mol NO would yield 0.736 mol $NaNO_2$ (in the presence of excess Na_2CO_3 and O_2), we conclude that Na_2CO_3 must be the limiting reactant; *the limiting reactant is the one that limits the amount of product obtained.* In checking the calculation of the mass of $NaNO_2$ obtained, we notice that the units work out properly. To check the final step, we can use our final answer to calculate the percent yield for the experiment: $(44.3/46.6) \times 100\% = 95\%$. This is the correct result for the percent yield.

PRACTICE EXAMPLE A: Hexamethylenediamine has the molecular formula $C_6H_{16}N_2$. It is one of the starting materials for the production of nylon. It can be prepared by the following reaction:

$$C_6H_{10}O_4(l) + NH_3(g) + H_2(g) \longrightarrow C_6H_{16}N_2(l) + H_2O(l) \text{ (not balanced)}$$

A large reaction vessel contains 4.15 kg $C_6H_{10}O_4$, 0.547 kg NH_3, and 0.172 kg H_2. If 1.46 kg $C_6H_{16}N_2$ is obtained, then what is the percent yield for the experiment?

PRACTICE EXAMPLE B: Zinc metal and aqueous hydrochloric acid, HCl(aq), react to give hydrogen gas, $H_2(g)$, and aqueous zinc chloride, $ZnCl_2(aq)$. A 0.4000 g sample of *impure* zinc reacts completely when added to 750.0 L of 0.0179 M HCl. After the reaction, the molarity of the HCl solution is determined to be 0.00403 M. What is the percent by mass of zinc in the sample?

Exercises

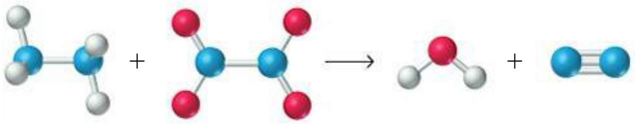
Writing and Balancing Chemical Equations

1. Balance the following equations by inspection.
   - **(a)** $SO_3 \longrightarrow SO_2 + O_2$
   - **(b)** $Cl_2O_7 + H_2O \longrightarrow HClO_4$
   - **(c)** $NO_2 + H_2O \longrightarrow HNO_3 + NO$
   - **(d)** $PCl_3 + H_2O \longrightarrow H_3PO_3 + HCl$
2. Balance the following equations by inspection.
   - **(a)** $P_2H_4 \longrightarrow PH_3 + P_4$
   - **(b)** $P_4 + Cl_2 \longrightarrow PCl_3$
   - **(c)** $FeCl_3 + H_2S \longrightarrow Fe_2S_3 + HCl$
   - **(d)** $Mg_3N_2 + H_2O \longrightarrow Mg(OH)_2 + NH_3$
3. Balance the following equations by inspection.
   - **(a)** $PbO + NH_3 \longrightarrow Pb + N_2 + H_2O$
   - **(b)** $FeSO_4 \longrightarrow Fe_2O_3 + SO_2 + O_2$
   - **(c)** $S_2Cl_2 + NH_3 \longrightarrow N_4S_4 + NH_4Cl + S_8$
   - **(d)** $C_3H_7CHOHCH(C_2H_5)CH_2OH + O_2 \longrightarrow CO_2 + H_2O$
4. Balance the following equations by inspection.
   - **(a)** $SO_2Cl_2 + HI \longrightarrow H_2S + H_2O + HCl + I_2$
   - **(b)** $FeTiO_3 + H_2SO_4 + H_2O \longrightarrow FeSO_4 \cdot 7\,H_2O + TiOSO_4$
   - **(c)** $Fe_3O_4 + HCl + Cl_2 \longrightarrow FeCl_3 + H_2O + O_2$
   - **(d)** $C_6H_5CH_2SSCH_2C_6H_5 + O_2 \longrightarrow CO_2 + SO_2 + H_2O$
5. Write balanced equations based on the information given.
   - **(a)** solid magnesium + oxygen gas ⟶ solid magnesium oxide
   - **(b)** nitrogen monoxide gas + oxygen gas ⟶ nitrogen dioxide gas
   - **(c)** gaseous ethane(C_2H_6) + oxygen gas ⟶ carbon dioxide gas + liquid water
   - **(d)** aqueous silver sulfate + aqueous barium iodide ⟶ solid barium sulfate + solid silver iodide
6. Write balanced equations based on the information given.
   - **(a)** solid magnesium + nitrogen gas ⟶ solid magnesium nitride
   - **(b)** solid potassium chlorate ⟶ solid potassium chloride + oxygen gas
   - **(c)** solid sodium hydroxide + solid ammonium chloride ⟶ solid sodium chloride + gaseous ammonia + water vapor
   - **(d)** solid sodium + liquid water ⟶ aqueous sodium hydroxide + hydrogen gas
7. Write balanced equations to represent the complete combustion of each of the following in excess oxygen: **(a)** butane, C_4H_{10}; **(b)** isopropyl alcohol, $CH_3CH(OH)CH_3$; **(c)** lactic acid, $CH_3CH(OH)COOH$.
8. Write balanced equations to represent the complete combustion of each of the following in excess oxygen: **(a)** propylene, C_3H_6; **(b)** thiobenzoic acid, C_6H_5COSH **(c)** glycerol, $CH_2(OH)CH(OH)CH_2OH$.

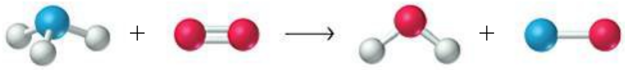
9. Write balanced equations to represent:
(a) the decomposition, by heating, of solid ammonium nitrate to produce dinitrogen monoxide gas (laughing gas) and water vapor
(b) the reaction of aqueous sodium carbonate with hydrochloric acid to produce water, carbon dioxide gas, and aqueous sodium chloride
(c) the reaction of methane (CH_4), ammonia, and oxygen gases to form gaseous hydrogen cyanide (HCN) and water vapor

10. Write balanced equations to represent:
(a) the reaction of sulfur dioxide gas with oxygen gas to produce sulfur trioxide gas (one of the reactions involved in the industrial preparation of sulfuric acid)
(b) the dissolving of limestone (calcium carbonate) in water containing dissolved carbon dioxide to produce calcium hydrogen carbonate (a reaction producing temporary hardness in groundwater)
(c) the reaction of ammonia and nitrogen monoxide to form nitrogen gas and water vapor

11. Write a balanced chemical equation for the reaction depicted below.



12. Write a balanced chemical equation for the reaction depicted below.



Stoichiometry of Chemical Reactions

13. In an experiment, 0.689 g Cr(s) reacts completely with 0.636 g $O_2(g)$ to form a single solid compound. Write a balanced chemical equation for the reaction.

14. A 3.104 g sample of an oxide of manganese contains 1.142 grams of oxygen. Write a balanced chemical equation for the reaction that produces the compound from Mn(s) and $O_2(g)$.

15. Iron metal reacts with chlorine gas. How many grams of $FeCl_3$ are obtained when 515 g Cl_2 reacts with excess Fe?

$$2\,Fe(s) + 3\,Cl_2(g) \longrightarrow 2\,FeCl_3(s)$$

16. If 46.3 g PCl_3 is produced by the reaction

$$6\,Cl_2(g) + P_4(s) \longrightarrow 4\,PCl_3(l)$$

how many grams each of Cl_2 and P_4 are consumed?

17. A laboratory method of preparing $O_2(g)$ involves the decomposition of $KClO_3(s)$.

$$2\,KClO_3(s) \xrightarrow{\Delta} 2\,KCl(s) + 3\,O_2(g)$$

(a) How many moles of $O_2(g)$ can be produced by the decomposition of 32.8 g $KClO_3$?
(b) How many grams of $KClO_3$ must decompose to produce 50.0 g O_2?
(c) How many grams of KCl are formed, together with 28.3 g O_2, in the decomposition of $KClO_3$?

18. A commercial method of manufacturing hydrogen involves the reaction of iron and steam.

$$3\,Fe(s) + 4\,H_2O(g) \xrightarrow{\Delta} Fe_3O_4(s) + 4\,H_2(g)$$

(a) How many grams of H_2 can be produced from 42.7 g Fe and an excess of $H_2O(g)$ (steam)?
(b) How many grams of H_2O are consumed in the conversion of 63.5 g Fe to Fe_3O_4?
(c) If 14.8 g H_2 is produced, how many grams of Fe_3O_4 must also be produced?

19. How many grams of Ag_2CO_3 are decomposed to yield 75.1 g Ag in this reaction?

$$Ag_2CO_3(s) \xrightarrow{\Delta} Ag(s) + CO_2(g) + O_2(g) \text{ (not balanced)}$$

20. How many kilograms of HNO_3 are consumed to produce 125 kg $Ca(H_2PO_4)_2$ in this reaction?

$$Ca_3(PO_4)_2 + HNO_3 \longrightarrow Ca(H_2PO_4)_2 + Ca(NO_3)_2 \text{ (not balanced)}$$

21. The reaction of calcium hydride with water can be used to prepare small quantities of hydrogen gas, as is done to fill weather-observation balloons.

$$CaH_2(s) + H_2O(l) \longrightarrow Ca(OH)_2(s) + H_2(g) \text{ (not balanced)}$$

(a) How many grams of $H_2(g)$ result from the reaction of 127 g CaH_2 with an excess of water?
(b) How many grams of water are consumed in the reaction of 56.2 g CaH_2?
(c) What mass of $CaH_2(s)$ must react with an excess of water to produce 8.12×10^{24} molecules of H_2?

22. The reaction of potassium superoxide, KO_2, is used in life-support systems to replace $CO_2(g)$ in expired air with $O_2(g)$. The unbalanced chemical equation for the reaction is given below.

$$KO_2(s) + CO_2(g) \longrightarrow K_2CO_3(s) + O_2(g)$$

(a) How many moles of $O_2(g)$ are produced by the reaction of 156 g $CO_2(g)$ with excess $KO_2(s)$?
(b) How many grams of $KO_2(s)$ are consumed per 100.0 g $CO_2(g)$ removed from expired air?
(c) How many O_2 molecules are produced per milligram of KO_2 consumed?

23. Iron ore is impure Fe_2O_3. When Fe_2O_3 is heated with an excess of carbon (coke), metallic iron and carbon monoxide gas are produced. From a sample of ore weighing 938 kg, 523 kg of pure iron is obtained. What is the mass percent Fe_2O_3, by mass, in the ore sample, assuming that none of the impurities contain Fe?

24. Solid silver oxide, $Ag_2O(s)$, decomposes at temperatures in excess of 300 °C, yielding metallic silver and oxygen gas. A 3.13 g sample of impure silver oxide yields 0.187 g $O_2(g)$. What is the mass percent Ag_2O in the sample? Assume that $Ag_2O(s)$ is the only source of $O_2(g)$. [*Hint:* Write a balanced equation for the reaction.]

25. Decaborane, $B_{10}H_{14}$, was used as a fuel for rockets in the 1950s. It reacts violently with oxygen, O_2, to produce B_2O_3 and water. Calculate the percentage by mass of $B_{10}H_{14}$ in a fuel mixture designed to ensure that $B_{10}H_{14}$ and O_2 run out at exactly the same time. (Such a mixture minimizes the mass of fuel that a rocket must carry.)

26. The rocket boosters of the space shuttle *Discovery*, launched on July 26, 2005, used a fuel mixture containing primarily solid ammonium perchlorate, $NH_4ClO_4(s)$, and aluminum metal. The unbalanced chemical equation for the reaction is given below.

$$\mathrm{Al(s) + NH_4ClO_4(s) \longrightarrow Al_2O_3(s) + AlCl_3(s) + H_2O(l) + N_2(g)}$$

What is the minimum mass of NH_4ClO_4 consumed, per kilogram of Al, by the reaction of NH_4ClO_4 and Al? [*Hint*: Balance the elements in the order Cl, H, O, Al, N.]

27. A piece of aluminum foil measuring 10.25 cm × 5.50 cm × 0.601 mm is dissolved in excess HCl(aq). What mass of $H_2(g)$ is produced? Use equation (4.2) and $d = 2.70\ \mathrm{g/cm^3}$ for Al.

28. An excess of aluminum foil is allowed to react with 225 mL of an aqueous solution of HCl ($d = 1.088$ g/mL) that contains 18.0% HCl by mass. What mass of $H_2(g)$ is produced? [*Hint:* Use equation (4.2).]

29. *Without performing detailed calculations*, which of the following metals yields the greatest amount of H_2 per gram of metal reacting with HCl(aq)? **(a)** Na, **(b)** Mg, **(c)** Al, **(d)** Zn. [*Hint:* Write equations similar to (4.2).]

30. *Without performing detailed calculations*, which of the following yields the same mass of $CO_2(g)$ per gram of compound as does ethanol, CH_3CH_2OH, when burned in excess oxygen? **(a)** H_2CO; **(b)** $HOCH_2CH_2OH$; **(c)** $HOCH_2CHOHCH_2OH$; **(d)** CH_3OCH_3; **(e)** C_6H_5OH.

Molarity

31. What are the molarities of the following solutes when dissolved in water?
(a) 2.92 mol CH_3OH in 7.16 L of solution
(b) 7.69 mmol CH_3CH_2OH in 50.00 mL of solution
(c) 25.2 g $CO(NH_2)_2$ in 275 mL of solution

32. What are the molarities of the following solutes when dissolved in water?
(a) 2.25×10^{-4} mol CH_3CH_2OH in 125 mL of solution
(b) 57.5 g $(CH_3)_2CO$ in 525 mL of solution
(c) 18.5 mL of $C_3H_5(OH)_3$ ($d = 1.26$ g/mL) in 375 mL of solution

33. What are the molarities of the following solutes?
(a) sucrose ($C_{12}H_{22}O_{11}$) if 150.0 g is dissolved per 250.0 mL of water solution
(b) urea, $CO(NH_2)_2$, if 98.3 mg of the 97.9% pure solid is dissolved in 5.00 mL of aqueous solution
(c) methanol, CH_3OH, ($d = 0.792$ g/mL) if 125.0 mL is dissolved in enough water to make 15.0 L of solution

34. What are the molarities of the following solutes?
(a) aspartic acid ($H_2C_4H_5NO_4$) if 0.405 g is dissolved in enough water to make 100.0 mL of solution
(b) acetone, C_3H_6O, ($d = 0.790$ g/mL) if 35.0 mL is dissolved in enough water to make 425 mL of solution
(c) diethyl ether, $(C_2H_5)_2O$, if 8.8 mg is dissolved in enough water to make 3.00 L of solution

35. How much
(a) glucose, $C_6H_{12}O_6$, in grams, must be dissolved in water to produce 75.0 mL of 0.350 M $C_6H_{12}O_6$?
(b) methanol, CH_3OH ($d = 0.792$ g/mL), in milliliters, must be dissolved in water to produce 2.25 L of 0.485 M CH_3OH?

36. How much
(a) ethanol, CH_3CH_2OH ($d = 0.789$ g/mL), in liters, must be dissolved in water to produce 200.0 L of 1.65 M CH_3CH_2OH?
(b) concentrated hydrochloric acid solution (36.0% HCl by mass; $d = 1.18$ g/mL), in milliliters, is required to produce 12.0 L of 0.234 M HCl?

37. In the United States, the concentration of glucose, $C_6H_{12}O_6$, in the blood is reported in units of milligrams per deciliter (mg/dL). In Canada, the United Kingdom, and elsewhere, the blood glucose concentration is reported in millimoles per liter (mmol/L), where 1 mmol $= 1 \times 10^{-3}$ mol. If a person has a blood glucose level of 85 mg/dL, then what is **(a)** the blood glucose level in mmol/L; **(b)** the molarity of glucose in the blood?

38. In many communities, water is fluoridated to prevent tooth decay. In the United States, for example, more than half of the population served by public water systems has access to water that is fluoridated at approximately 1 mg F^- per liter. **(a)** What is the molarity of F^- in water if it contains 1.2 mg F^- per liter? **(b)** How many grams of solid KF should be added to a 1.6×10^8 L water reservoir to give a fluoride concentration of 1.2 mg F^- per liter?

39. Which of the following is a 0.500 M KCl solution? **(a)** 0.500 g KCl/mL solution; **(b)** 36.0 g KCl/L solution; **(c)** 7.46 mg KCl/mL solution; **(d)** 373 g KCl in 10.00 L solution

40. Which two solutions have the same concentration? **(a)** 55.45 g NaCl/L solution; **(b)** 5.545 g NaCl/100 g solution; **(c)** 55.45 g NaCl/kg water; **(d)** 55.45 mg NaCl/1.00 mL solution; **(e)** 5.00 mmol NaCl/5.00 mL solution

41. Which has the higher concentration of sucrose: a 46% sucrose solution by mass ($d = 1.21$ g/mL), or 1.50 M $C_{12}H_{22}O_{11}$? Explain your reasoning.

42. Which has the greater molarity of ethanol: a white wine ($d = 0.95$ g/mL) with 11% CH_3CH_2OH by mass, or the solution described in Example 4-8? Explain your reasoning.

43. A 10.00 mL sample of 2.05 M KNO_3 is diluted to a volume of 250.0 mL. What is the concentration of the diluted solution?

44. What volume of 0.750 M $AgNO_3$ must be diluted with water to prepare 250.0 mL of 0.425 M $AgNO_3$?

45. Water is evaporated from 125 mL of 0.198 M K_2SO_4 solution until the volume becomes 105 mL. What is the molarity of K_2SO_4 in the remaining solution?

46. A 25.0 mL sample of HCl(aq) is diluted to a volume of 500.0 mL. If the concentration of the diluted solution is found to be 0.085 M HCl, what was the concentration of the original solution?

47. Given a 0.250 M K_2CrO_4 stock solution, describe how you would prepare a solution that is 0.0125 M K_2CrO_4. That is, what combination(s) of pipet and volumetric flask would you use? Typical sizes of volumetric flasks found in a general chemistry laboratory are 100.0, 250.0, 500.0, and 1000.0 mL, and typical sizes of volumetric pipets are 1.00, 5.00, 10.00, 25.00, and 50.00 mL.

48. Given two liters of 0.496 M KCl, describe how you would use this solution to prepare 250.0 mL of 0.175 M KCl. Give sufficient details so that another student could follow your instructions.

Chemical Reactions in Solution

49. Consider the reaction below:

$$2\,AgNO_3(aq) + Na_2S(aq) \longrightarrow Ag_2S(s) + 2\,NaNO_3(aq)$$

(a) How many grams of $Na_2S(s)$ are required to react completely with 27.8 mL of 0.163 M $AgNO_3$?
(b) How many grams of $Ag_2S(s)$ are obtained from the reaction in part **(a)**?

50. Excess $NaHCO_3$ is added to 525 mL of 0.220 M $Cu(NO_3)_2$. These substances react as follows:

$$Cu(NO_3)_2(aq) + 2\,NaHCO_3(s) \longrightarrow CuCO_3(s) + 2\,NaNO_3(aq) + H_2O(l) + CO_2(g)$$

(a) How many grams of the $NaHCO_3(s)$ will be consumed?
(b) How many grams of $CuCO_3(s)$ will be produced?

51. How many milliliters of 0.650 M K_2CrO_4 are needed to precipitate all the silver in 415 mL of 0.186 M $AgNO_3$ as $Ag_2CrO_4(s)$?

$$2\,AgNO_3(aq) + K_2CrO_4(aq) \longrightarrow Ag_2CrO_4(s) + 2\,KNO_3(aq)$$

52. Consider the reaction below.

$$Ca(OH)_2(s) + 2\,HCl(aq) \longrightarrow CaCl_2(aq) + 2\,H_2O(l)$$

(a) How many grams of $Ca(OH)_2$ are required to react completely with 415 mL of 0.477 M HCl?
(b) How many kilograms of $Ca(OH)_2$ are required to react with 324 L of a HCl solution that is 24.28% HCl by mass, and has a density of 1.12 g/mL?

53. Exactly 1.00 mL of an aqueous solution of HNO_3 is diluted to 100.0 mL. It takes 29.78 mL of 0.0142 M $Ca(OH)_2$ to convert all of the HNO_3 to $Ca(NO_3)_2$. The other product of the reaction is water. Calculate the molarity of the undiluted HNO_3 solution.

54. A 5.00 mL sample of an aqueous solution of $Na_2H_3PO_4$ requires 49.1 mL of 0.217 M NaOH to convert all of the $Na_2H_3PO_4$ to Na_3PO_4. The other product of the reaction is water. Calculate the molarity of the $Na_2H_3PO_4$ solution.

55. Refer to Example 4-7 and equation (4.2). For the conditions stated in Example 4-7, determine **(a)** the number of moles of $AlCl_3$ and **(b)** the molarity of the $AlCl_3(aq)$ if the solution volume is simply the 23.8 mL calculated in the example.

56. Refer to the Integrative Example on page 139. If 138 g Na_2CO_3 in 1.42 L of aqueous solution is treated with an excess of NO(g) and $O_2(g)$, what is the molarity of the $NaNO_2(aq)$ solution that results? (Assume that the reaction goes to completion.)

57. How many grams of Ag_2CrO_4 will precipitate if excess $K_2CrO_4(aq)$ is added to the 415 mL of 0.186 M $AgNO_3$ in Exercise 51?

58. What volume of 0.0797 M $KMnO_4$ is necessary to convert 9.13 g KI to I_2 in the reaction below? Assume that H_2SO_4 is present in excess.

$$2\,KMnO_4 + 10\,KI + 8\,H_2SO_4 \longrightarrow 6\,K_2SO_4 + 2\,MnSO_4 + 5\,I_2 + 8\,H_2O$$

59. How many grams of sodium must react with 155 mL H_2O to produce a solution that is 0.175 M NaOH? (Assume a final solution volume of 155 mL.)

$$2\,Na(s) + 2\,H_2O(l) \longrightarrow 2\,NaOH(aq) + H_2(g)$$

60. A method of lowering the concentration of HCl(aq) is to allow the solution to react with a small quantity of Mg. How many milligrams of Mg must be added to 250.0 mL of 1.023 M HCl to reduce the solution concentration to exactly 1.000 M HCl?

$$Mg(s) + 2\,HCl(aq) \longrightarrow MgCl_2(aq) + H_2(g)$$

61. A 0.3126 g sample of oxalic acid, $H_2C_2O_4$, requires 26.21 mL of a particular concentration of NaOH(aq) to complete the following reaction. What is the molarity of the NaOH(aq)?

$$H_2C_2O_4(s) + 2\,NaOH(aq) \longrightarrow Na_2C_2O_4(aq) + 2\,H_2O(l)$$

62. A 25.00 mL sample of HCl(aq) was added to a 0.1000 g sample of $CaCO_3$. All the $CaCO_3$ reacted, leaving some excess HCl(aq).

$$CaCO_3(s) + 2\,HCl(aq) \longrightarrow CaCl_2(aq) + H_2O(l) + CO_2(g)$$

The excess HCl(aq) required 43.82 mL of 0.01185 M $Ba(OH)_2$ to complete the following reaction. What was the molarity of the original HCl(aq)?

$$2\,HCl(aq) + Ba(OH)_2(aq) \longrightarrow BaCl_2(aq) + 2\,H_2O(l)$$

Determining the Limiting Reactant

63. How many moles of NO(g) can be produced in the reaction of 3.00 mol $NH_3(g)$ and 4.00 mol $O_2(g)$?

$$4\,NH_3(g) + 5\,O_2(g) \xrightarrow{\Delta} 4\,NO(g) + 6\,H_2O(l)$$

64. The reaction of calcium hydride and water produces calcium hydroxide and hydrogen as products. How many moles of $H_2(g)$ will be formed in the reaction between 0.82 mol $CaH_2(s)$ and 1.54 mol $H_2O(l)$?

65. A 0.696 mol sample of Cu is added to 136 mL of 6.0 M HNO_3. Assuming the following reaction is the only one that occurs, will the Cu react completely?

$$3\,Cu(s) + 8\,HNO_3(aq) \longrightarrow 3\,Cu(NO_3)_2(aq) + 4\,H_2O(l) + 2\,NO(g)$$

66. How many grams of $H_2(g)$ are produced by the reaction of 1.84 g Al with 75.0 mL of 2.95 M HCl? [*Hint:* Recall equation (4.2).]

67. A side reaction in the manufacture of rayon from wood pulp is

$$3\,CS_2 + 6\,NaOH \longrightarrow 2\,Na_2CS_3 + Na_2CO_3 + 3\,H_2O$$

How many grams of Na_2CS_3 are produced in the reaction of 92.5 mL of liquid CS_2 ($d = 1.26$ g/mL) and 2.78 mol NaOH?

68. Lithopone is a brilliant white pigment used in water-based interior paints. It is a mixture of $BaSO_4$ and ZnS produced by the reaction

$$BaS(aq) + ZnSO_4(aq) \longrightarrow \underbrace{ZnS(s) + BaSO_4(s)}_{\text{lithopone}}$$

How many grams of lithopone are produced in the reaction of 315 mL of 0.275 M $ZnSO_4$ and 285 mL of 0.315 M BaS?

69. Ammonia can be generated by heating together the solids NH_4Cl and $Ca(OH)_2$. $CaCl_2$ and H_2O are also formed. **(a)** If a mixture containing 33.0 g each of NH_4Cl and $Ca(OH)_2$ is heated, how many grams of NH_3 will form? **(b)** Which reactant remains in excess, and in what mass?

70. Chlorine can be generated by heating together calcium hypochlorite and hydrochloric acid. Calcium chloride and water are also formed. **(a)** If 50.0 g $Ca(OCl)_2$ and 275 mL of 6.00 M HCl are allowed to react, how many grams of chlorine gas will form? **(b)** Which reactant, $Ca(OCl)_2$ or HCl, remains in excess, and in what mass?

71. Chromium(II) sulfate, $CrSO_4$, is a reagent that has been used in certain applications to help reduce carbon–carbon double bonds ($C{=}C$) in molecules to single bonds ($C{-}C$). The reagent can be prepared via the following reaction.

$$4\,Zn(s) + K_2Cr_2O_7(aq) + 7\,H_2SO_4(aq) \longrightarrow 4\,ZnSO_4(aq) + 2\,CrSO_4(aq) + K_2SO_4(aq) + 7\,H_2O(l)$$

What is the maximum number of grams of $CrSO_4$ that can be made from a reaction mixture containing 3.2 mol Zn, 1.7 mol $K_2Cr_2O_7$, and 5.0 mol H_2SO_4?

72. Titanium tetrachloride, $TiCl_4$, is prepared by the reaction below.

$$3\,TiO_2(s) + 4\,C(s) + 6\,Cl_2(g) \longrightarrow 3\,TiCl_4(g) + 2\,CO_2(g) + 2\,CO(g)$$

What is the maximum mass of $TiCl_4$ that can be obtained from 35 g TiO_2, 45 g Cl_2, and 11 g C?

Theoretical, Actual, and Percent Yields

73. In the reaction of 277 g CCl_4 with an excess of HF, 187 g CCl_2F_2 is obtained. What are the **(a)** theoretical, **(b)** actual, and **(c)** percent yields of this reaction?

$$CCl_4 + 2\,HF \longrightarrow CCl_2F_2 + 2\,HCl$$

74. In the reaction shown, 100.0 g $C_6H_{11}OH$ yielded 64.0 g C_6H_{10}. **(a)** What is the theoretical yield of the reaction? **(b)** What is the percent yield? **(c)** What mass of $C_6H_{11}OH$ would produce 100.0 g C_6H_{10} if the percent yield is that determined in part **(b)**?

$$C_6H_{11}OH \longrightarrow C_6H_{10} + H_2O$$

75. Cryolite, Na_3AlF_6, is an important industrial reagent. It is made by the reaction below.

$$Al_2O_3(s) + 6\,NaOH(aq) + 12\,HF(g) \longrightarrow 2\,Na_3AlF_6(s) + 9\,H_2O(l)$$

In an experiment, 7.81 g Al_2O_3 and excess HF(g) were dissolved in 3.50 L of 0.141 M NaOH. If 28.2 g Na_3AlF_6 was obtained, then what is the percent yield for this experiment?

76. Nitrogen gas, N_2, can be prepared by passing gaseous ammonia over solid copper(II) oxide, CuO, at high temperatures. The other products of the reaction are solid copper, Cu, and water vapor. In a certain experiment, a reaction mixture containing 18.1 g NH_3 and 90.4 g CuO yields 6.63 g N_2. Calculate the percent yield for this experiment.

77. The reaction of 15.0 g C_4H_9OH, 22.4 g NaBr, and 32.7 g H_2SO_4 yields 17.1 g C_4H_9Br in the reaction shown. What are the **(a)** theoretical yield, **(b)** actual yield, and **(c)** percent yield of this reaction?

$$C_4H_9OH + NaBr + H_2SO_4 \longrightarrow C_4H_9Br + NaHSO_4 + H_2O$$

78. Azobenzene, an intermediate in the manufacture of dyes, can be prepared from nitrobenzene by reaction with triethylene glycol in the presence of Zn and KOH. In one reaction, 0.10 L of nitrobenzene ($d = 1.20$ g/mL) and 0.30 L of triethylene glycol ($d = 1.12$ g/mL) yields 55 g azobenzene. What are the **(a)** theoretical yield, **(b)** actual yield, and **(c)** percent yield of this reaction?

$$\underset{\text{nitrobenzene}}{2\,C_6H_5NO_2} + \underset{\text{triethylene glycol}}{4\,C_6H_{14}O_4} \xrightarrow[\text{KOH}]{\text{Zn}} \underset{\text{azobenzene}}{(C_6H_5N)_2} + 4\,C_6H_{12}O_4 + 4\,H_2O$$

79. How many grams of commercial acetic acid (97% CH_3COOH by mass) must be allowed to react with an excess of PCl_3 to produce 75 g of acetyl chloride (CH_3COCl), if the reaction has a 78.2% yield?

$$CH_3COOH + PCl_3 \longrightarrow CH_3COCl + H_3PO_3 \text{ (not balanced)}$$

80. Suppose that reactions **(a)** and **(b)** each have a 92% yield. Starting with 112 g CH_4 in reaction **(a)** and an excess of $Cl_2(g)$, how many grams of CH_2Cl_2 are formed in reaction **(b)**?

(a) $CH_4 + Cl_2 \longrightarrow CH_3Cl + HCl$

(b) $CH_3Cl + Cl_2 \longrightarrow CH_2Cl_2 + HCl$

81. An essentially 100% yield is necessary for a chemical reaction used to *analyze* a compound, but it is almost never expected for a reaction that is used to *synthesize* a compound. Explain this difference.

82. Suppose we carry out the precipitation of $Ag_2CrO_4(s)$ described in Example 4-11. If we obtain 2.058 g of precipitate, we might conclude that it is nearly pure $Ag_2CrO_4(s)$, but if we obtain 2.112 g, we can be quite sure that the precipitate is not pure. Explain this difference.

Consecutive Reactions, Simultaneous Reactions

83. How many grams of HCl are consumed in the reaction of 425 g of a mixture containing 35.2% $MgCO_3$ and 64.8% $Mg(OH)_2$, by mass?

$$\begin{aligned} Mg(OH)_2 + 2\,HCl &\longrightarrow MgCl_2 + 2\,H_2O \\ MgCO_3 + 2\,HCl &\longrightarrow MgCl_2 + H_2O + CO_2(g) \end{aligned}$$

84. How many grams of CO_2 are produced in the complete combustion of 406 g of a bottled gas that consists of 72.7% propane (C_3H_8) and 27.3% butane (C_4H_{10}), by mass?

85. Dichlorodifluoromethane, once widely used as a refrigerant, can be prepared by the reactions shown. How many moles of Cl_2 must be consumed in the first reaction to produce 2.25 kg CCl_2F_2 in the second? Assume that all the CCl_4 produced in the first reaction is consumed in the second.

$$\begin{aligned} CH_4 + Cl_2 &\longrightarrow CCl_4 + HCl \text{ (not balanced)} \\ CCl_4 + HF &\longrightarrow CCl_2F_2 + HCl \text{ (not balanced)} \end{aligned}$$

86. Carbon dioxide gas, $CO_2(g)$, produced in the combustion of a sample of ethane is absorbed in $Ba(OH)_2(aq)$, producing 0.506 g $BaCO_3(s)$. How many grams of ethane (C_2H_6) must have been burned?

$$C_2H_6(g) + O_2(g) \longrightarrow CO_2(g) + H_2O(l) \text{ (not balanced)}$$

$$CO_2(g) + Ba(OH)_2(aq) \longrightarrow BaCO_3(s) + H_2O(l)$$

87. The following process has been used to obtain iodine from oil-field brines in California. How many kilograms of silver nitrate are required in the first step for every kilogram of iodine produced in the third step?

sodium iodide + silver nitrate ⟶ silver iodide + sodium nitrate

silver iodide + iron ⟶ iron(II) iodide + silver

iron(II) iodide + chlorine gas ⟶ iron(III) chloride + solid iodine

88. Sodium bromide, used to produce silver bromide for use in photography, can be prepared as shown. How many kilograms of iron are consumed to produce 2.50×10^3 kg NaBr?

$$\begin{aligned} Fe + Br_2 &\longrightarrow FeBr_2 \\ FeBr_2 + Br_2 &\longrightarrow Fe_3Br_8 \text{ (not balanced)} \\ Fe_3Br_8 + Na_2CO_3 &\longrightarrow NaBr + CO_2 + Fe_3O_4 \text{ (not balanced)} \end{aligned}$$

89. High-purity silicon is obtained using a three-step process. The first step involves heating solid silicon dioxide, SiO_2, with solid carbon to give solid silicon and carbon monoxide gas. In the second step, solid silicon is converted into liquid silicon tetrachloride, $SiCl_4$, by treating it with chlorine gas. In the last step, $SiCl_4$ is treated with hydrogen gas to give ultrapure solid silicon and hydrogen chloride gas.

(a) Write balanced chemical equations for the steps involved in this three-step process.

(b) Calculate the masses of carbon, chlorine, and hydrogen required per kilogram of silicon.

90. The following set of reactions is to be used as the basis of a method for producing nitric acid, HNO_3. Calculate the minimum masses of N_2, H_2, and O_2 required per kilogram of HNO_3.

$$\begin{aligned} &N_2(g) + 3\,H_2(g) \longrightarrow 2\,NH_3(g) \\ &4\,NH_3(g) + 5\,O_2(g) \longrightarrow 4\,NO(g) + 6\,H_2O(g) \\ &2\,NO(g) + O_2(g) \longrightarrow 2\,NO_2(g) \\ &3\,NO_2(g) + H_2O(l) \longrightarrow 2\,HNO_3(aq) + NO(g) \end{aligned}$$

91. When a solid mixture of $MgCO_3$ and $CaCO_3$ is heated strongly, carbon dioxide gas is given off and a solid mixture of MgO and CaO is obtained. If a 24.00 g sample of a mixture of $MgCO_3$ and $CaCO_3$ produces 12.00 g CO_2, then what is the percentage by mass of $MgCO_3$ in the original mixture?

92. A mixture of Fe_2O_3 and FeO was analyzed and found to be 72.0% Fe by mass. What is the percentage by mass of Fe_2O_3 in the mixture?

Integrative and Advanced Exercises

93. Write chemical equations to represent the following reactions.

(a) Limestone rock (calcium carbonate) is heated (calcined) and decomposes to calcium oxide and carbon dioxide gas.

(b) Zinc sulfide ore is heated in air (roasted) and is converted to zinc oxide and sulfur dioxide gas. (Note that oxygen gas in the air is also a reactant.)

(c) Propane gas reacts with gaseous water to produce a mixture of carbon monoxide and hydrogen gases. (This mixture, called *synthesis gas*, is used to produce a variety of organic chemicals.)

(d) Sulfur dioxide gas is passed into an aqueous solution containing sodium sulfide and sodium carbonate. The reaction products are carbon dioxide and an aqueous solution of sodium thiosulfate.

94. Write chemical equations to represent the following reactions.

(a) Calcium phosphate is heated with silicon dioxide and carbon, producing calcium silicate ($CaSiO_3$), phosphorus (P_4), and carbon monoxide. The phosphorus and chlorine react to form phosphorus trichloride, and the phosphorus trichloride and water react to form phosphorous acid.

(b) Copper metal reacts with gaseous oxygen, carbon dioxide, and water to form green basic copper carbonate, $Cu_2(OH)_2CO_3$ (a reaction responsible for the formation of the green patina, or coating, often seen on outdoor bronze statues).

(c) White phosphorus and oxygen gas react to form tetraphosphorus decoxide. The tetraphosphorus decoxide reacts with water to form an aqueous solution of phosphoric acid.

(d) Calcium dihydrogen phosphate reacts with sodium hydrogen carbonate (bicarbonate), producing calcium phosphate, sodium hydrogen phosphate, carbon dioxide, and water (the principal reaction occurring when ordinary baking powder is added to cakes, bread, and biscuits).

95. The three astronauts aboard *Apollo 13*, which was launched in 1970 on April 11 and returned to Earth on April 17, were kept alive during their mission, in part, because of lithium hydroxide (LiOH) canisters that were designed to remove exhaled CO_2 from the air. Solid lithium hydroxide reacts with $CO_2(g)$ to give solid Li_2CO_3 and water. With the assumption that an astronaut exhales approximately 1.00 kg CO_2 per day, what mass of LiOH was required to remove all of the CO_2 exhaled by the three-member crew on their six-day mission?

96. Chalkboard chalk is made from calcium carbonate and calcium sulfate, with minor impurities such as SiO_2. Only the $CaCO_3$ reacts with dilute HCl(aq). What is the mass percent $CaCO_3$ in a piece of chalk if a 3.28-g sample yields 0.981 g $CO_2(g)$?

$$CaCO_3(s) + 2\,HCl(aq) \longrightarrow CaCl_2(aq) + H_2O(l) + CO_2(g)$$

97. Hydrogen gas, $H_2(g)$, is passed over $Fe_2O_3(s)$ at 400 °C. Water vapor is formed together with a black residue—a compound consisting of 72.3% Fe and 27.7% O. Write a balanced equation for this reaction.

98. A sulfide of iron, containing 36.5% S by mass, is heated in $O_2(g)$, and the products are sulfur dioxide and an oxide of iron containing 27.6% O, by mass. Write a balanced chemical equation for this reaction.

99. Water and ethanol, $CH_3CH_2OH(l)$, are miscible, that is, they can be mixed in all proportions. However, when these liquids are mixed, the total volume of the resulting solution is not equal to the sum of the pure liquid volumes, and we say that the volumes are not additive. For example, when 50.0 mL of water and 50.0 mL of $CH_3CH_2OH(l)$, are mixed at 20 °C, the total volume of the solution is 96.5 mL, not 100.0 mL. (The volumes are not additive because the interactions and packing of water molecules are slightly different from the interactions and packing of CH_3CH_2OH molecules.) Calculate the molarity of CH_3CH_2OH in a solution prepared by mixing 50.0 mL of water and 50.0 mL of $CH_3CH_2OH(l)$ at 20 °C. At this temperature, the densities of water and ethanol are 0.99821 g/mL and 0.7893 g/mL, respectively.

100. When water and methanol, $CH_3OH(l)$, are mixed, the total volume of the resulting solution is not equal to the sum of the pure liquid volumes. (Refer to Exercise 99 for an explanation.) When 72.061 g H_2O and 192.25 g CH_3OH are mixed at 25 °C, the resulting solution has a density of 0.86070 g/mL. At 25 °C, the densities of water and methanol are 0.99705 g/mL and 0.78706 g/mL, respectively.

(a) Calculate the volumes of the pure liquid samples and the solution, and show that the pure liquid volumes are not additive. [*Hint*: Although the volumes are not additive, the masses are.]

(b) Calculate the molarity of CH_3OH in this solution.

101. What volume of 0.149 M HCl must be added to 1.00×10^2 mL of 0.285 M HCl so that the resulting solution has a molarity of 0.205 M? Assume that the volumes are additive.

102. What volume of 0.0175 M CH_3OH must be added to 50.0 mL of 0.0248 M CH_3OH so that the resulting solution has a molarity of exactly 0.0200 M? Assume that the volumes are additive.

103. What is the molarity of NaCl(aq) if a solution has 1.52 ppm Na? Assume that NaCl is the only source of Na and that the solution density is 1.00 g/mL. (The unit *ppm* is parts per million; here it can be taken to mean g Na per million grams of solution.)

104. How many milligrams $Ca(NO_3)_2$ must be present in 50.0 L of a solution containing 2.35 ppm Ca? [*Hint:* See also Exercise 103.]

105. A drop (0.05 mL) of 12.0 M HCl is spread over a sheet of thin aluminum foil. Assume that all the acid reacts with, and thus dissolves through, the foil. What will be the area, in cm^2, of the cylindrical hole produced? (Density of Al = 2.70 g/cm^3; foil thickness = 0.10 mm.)

$$2\,Al(s) + 6\,HCl(aq) \longrightarrow 2\,AlCl_3(aq) + 3\,H_2(g)$$

106. A small piece of zinc is dissolved in 50.00 mL of 1.035 M HCl. At the conclusion of the reaction, the concentration of the 50.00 mL sample is redetermined and found to be 0.812 M HCl. What must have been the mass of the piece of zinc that dissolved?

$$Zn(s) + 2\,HCl(aq) \longrightarrow ZnCl_2(aq) + H_2(g)$$

107. How many milliliters of 0.715 M NH_4NO_3 solution must be diluted with water to produce 1.00 L of a solution with a concentration of 2.37 mg N/mL?

108. A seawater sample has a density of 1.03 g/mL and 2.8% NaCl by mass. A saturated solution of NaCl in water is 5.45 M NaCl. How many liters of water would have to be evaporated from 1.00×10^6 L of the seawater before NaCl would begin to crystallize? (A saturated solution contains the maximum amount of dissolved solute possible.)

109. A 99.8 mL sample of a solution that is 12.0% KI by mass (d = 1.093 g/mL) is added to 96.7 mL of another solution that is 14.0% $Pb(NO_3)_2$ by mass (d = 1.134 g/mL). How many grams of PbI_2 should form?

$$Pb(NO_3)_2(aq) + 2\,KI(aq) \longrightarrow PbI_2(s) + 2\,KNO_3(aq)$$

110. Solid calcium carbonate, $CaCO_3(s)$, reacts with $HCl(aq)$ to form H_2O, $CaCl_2(aq)$, and $CO_2(g)$. If a 45.0 g sample of $CaCO_3(s)$ is added to 1.25 L of $HCl(aq)$ that is 25.7% HCl by mass ($d = 1.13$ g/mL), what will be the molarity of HCl in the solution after the reaction is completed? Assume that the solution volume remains constant.

111. A 2.05 g sample of an iron–aluminum alloy (ferroaluminum) is dissolved in excess $HCl(aq)$ to produce 0.105 g $H_2(g)$. What is the percent composition, by mass, of the ferroaluminum?

$$Fe(s) + 2\,HCl(aq) \longrightarrow FeCl_2(aq) + H_2(g)$$
$$2\,Al(s) + 6\,HCl(aq) \longrightarrow 2\,AlCl_3(aq) + 3\,H_2(g)$$

112. A 0.155 g sample of an Al–Mg alloy reacts with an excess of $HCl(aq)$ to produce 0.0163 g H_2. What is the percent Mg in the alloy?
[*Hint:* Write equations similar to (4.2).]

113. An organic liquid is either methyl alcohol (CH_3OH), ethyl alcohol (CH_3CH_2OH), or a mixture of the two. A 0.220-g sample of the liquid is burned in an excess of $O_2(g)$ and yields 0.352 g $CO_2(g)$. Is the liquid a pure alcohol or a mixture of the two?

114. The manufacture of ethyl alcohol, CH_3CH_2OH, yields diethyl ether, $(C_2H_5)_2O$ as a by-product. The complete combustion of a 1.005 g sample of the product of this process yields 1.963 g CO_2. What must be the mass percents of (CH_3CH_2OH), and of $(C_2H_5)_2O$ in this sample?

115. A mixture contains only $CuCl_2$ and $FeCl_3$. A 0.7391 g sample of the mixture is completely dissolved in water and then treated with $AgNO_3(aq)$. The following reactions occur.

$$CuCl_2(aq) + 2\,AgNO_3(aq) \longrightarrow 2\,AgCl(s) + Cu(NO_3)_2(aq)$$
$$FeCl_3(aq) + 3\,AgNO_3(aq) \longrightarrow 3\,AgCl(s) + Fe(NO_3)_3(aq)$$

If it takes 86.91 mL of 0.1463 M $AgNO_3$ solution to precipitate all the chloride as AgCl, then what is the percentage by mass of copper in the mixture?

116. Under appropriate conditions, copper sulfate, potassium chromate, and water react to form a product containing Cu^{2+}, $CrO_4{}^{2-}$, and OH^- ions. Analysis of the compound yields 48.7% Cu^{2+}, 35.6% $CrO_4{}^{2-}$, and 15.7% OH^-.

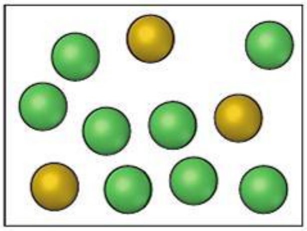
(a) Determine the empirical formula of the compound.
(b) Write a plausible equation for the reaction.

117. Write a chemical equation to represent the complete combustion of malonic acid, a compound with 34.62% C, 3.88% H, and 61.50% O, by mass.

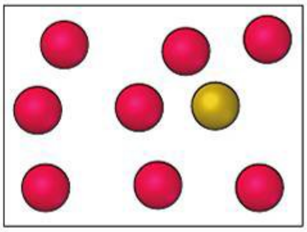
118. Aluminum metal and iron(III) oxide react to give aluminum oxide and iron metal. What is the maximum mass of iron that can be obtained from a reaction mixture containing 2.5 g of aluminum and 9.5 g of iron(III) oxide. What mass of the excess reactant remains?

119. Silver nitrate is a very expensive chemical. For a particular experiment, you need 100.0 mL of 0.0750 M $AgNO_3$, but only 60 mL of 0.0500 M $AgNO_3$ is available. You decide to pipet exactly 50.00 mL of the solution into a 100.0 mL flask, add an appropriate mass of $AgNO_3$, and then dilute the resulting solution to exactly 100.0 mL. What mass of $AgNO_3$ must you use?

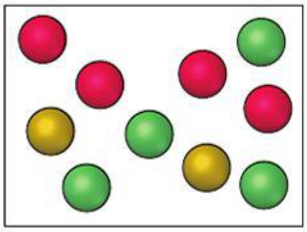
120. When sulfur (S_8) and chlorine are mixed in a reaction vessel, disulfur dichloride is the sole product. The starting mixture below is represented by yellow spheres for the S_8 molecules and green spheres for the chlorine molecules.



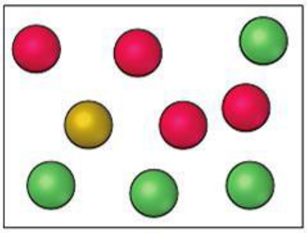
Which of the following is (are) a valid representation(s) of the contents of the reaction vessel after some disulfur dichloride (represented by red spheres) has formed?



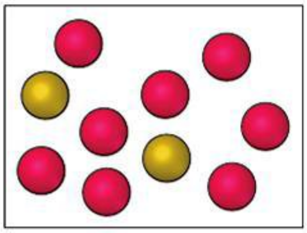
(a)



(b)



(c)



(d)

121. A method for eliminating oxides of nitrogen (e.g., NO_2) from automobile exhaust gases is to pass the exhaust gases over solid cyanuric acid, $C_3N_3(OH)_3$. When the hot exhaust gases come in contact with cyanuric acid, solid $C_3N_3(OH)_3$ decomposes into isocyanic acid vapor, $HNCO(g)$, which then reacts with NO_2 in the exhaust gases to give N_2, CO_2, and H_2O. How many grams of $C_3N_3(OH)_3$ are needed per gram of NO_2 in this method?
[*Hint*: To balance the equation for reaction between HNCO and NO_2, balance with respect to each kind of atom in this order: H, C, O, and N.]

122. For a specific reaction, ammonium dichromate is the only reactant and chromium(III) oxide and water are two of the three products. What is the third product and how many grams of this product are produced per kilogram of ammonium dichromate decomposed?

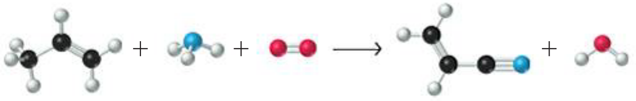
123. It is desired to produce as large a volume of 1.25 M urea $[CO(NH_2)_2(aq)]$ as possible from these three sources: 345 mL of 1.29 M $CO(NH_2)_2$, 485 mL of 0.653 M $CO(NH_2)_2$, and 835 mL of 0.775 M $CO(NH_2)_2$. How can this be done? What is the maximum volume of this solution obtainable?

124. The mineral ilmenite, $FeTiO_3$, is an important source of titanium dioxide for use as a white pigment. In the first step in its conversion to titanium dioxide, ilmenite is treated with sulfuric acid and water to form $TiOSO_4$ and iron(II) sulfate heptahydrate. Titanium dioxide is obtained in two subsequent steps. How many kilograms of iron(II) sulfate heptahydrate are produced for every 1.00×10^3 kg of ilmenite processed?

125. Refer to Exercise 124. Iron(II) sulfate heptahydrate formed in the processing of ilmenite ore cannot be released into the environment. Its further treatment involves dehydration by heating to produce anhydrous iron(II) sulfate. Upon further heating, the iron(II) sulfate decomposes to iron(III) oxide, and sulfur dioxide and oxygen gases. The iron(III) oxide is used in the production of iron and steel. How many kilograms of iron(III) oxide are obtained for every 1.00×10^3 kg of iron(II) sulfate heptahydrate?

126. Melamine, $C_3N_3(NH_2)_3$, is used in adhesives and resins. It is manufactured in a two-step process in which urea, $CO(NH_2)_2$, is the sole starting material, isocyanic acid (HNCO) is an intermediate, and ammonia and carbon dioxide gases are by-products.
(a) Write a balanced equation for the overall reaction.
(b) What mass of melamine will be obtained from 100.0 kg of urea if the yield of the overall reaction is 84%?

127. Acrylonitrile is used in the production of synthetic fibers, plastics, and rubber goods. It can be prepared from propylene (propene), ammonia, and oxygen in the reaction illustrated below.
(a) Write a balanced chemical equation for this reaction.
(b) The actual yield of the reaction is 0.73 kg acrylonitrile per kilogram of propylene. What is the minimum mass of ammonia required to produce 1.00 metric ton (1000 kg) of acrylonitrile?



128. It is often difficult to determine the concentration of a species in solution, particularly if it is a biological species that takes part in complex reaction pathways. One way to do this is through a dilution experiment with labeled molecules. Instead of molecules, however, we will use fish.

An angler wants to know the number of fish in a particular pond, and so puts an indelible mark on 100 fish and adds them to the pond's existing population. After waiting for the fish to spread throughout the pond, the angler starts fishing, eventually catching 18 fish. Of these, five are marked. What is the total number of fish in the pond?

Feature Problems

129. Lead nitrate and potassium iodide react in aqueous solution to form a yellow precipitate of lead iodide. In one series of experiments, the masses of the two reactants were varied, but the *total* mass of the two was held constant at 5.000 g. The lead iodide formed was filtered from solution, washed, dried, and weighed. The table gives data for a series of reactions.

Experiment	Mass of Lead Nitrate, g	Mass of Lead Iodide, g
1	0.500	0.692
2	1.000	1.388
3	1.500	2.093
4	3.000	2.778
5	4.000	1.391

(a) Plot the data in a graph of mass of lead iodide versus mass of lead nitrate, and draw the appropriate curve(s) connecting the data points. What is the maximum mass of precipitate that can be obtained?
(b) Explain why the maximum mass of precipitate is obtained when the reactants are in their stoichiometric proportions. What are these stoichiometric proportions expressed as a mass ratio, and as a mole ratio?
(c) Show how the stoichiometric proportions determined in part **(b)** are related to the balanced equation for the reaction.

130. The emerging field of *green chemistry* comprises all the methods used to minimize the environmental impact of chemical activities. One of the dozen or so factors in green chemistry is *atom economy*—the efficiency in rearranging the atoms in a set of reactants into the desired product. Atom economy (AE) is expressed as a percentage by the equation

$$\text{AE} = \frac{\text{formula mass of desired product}}{\begin{array}{c}\text{sum of formula masses}\\ \text{of all the reactants}\end{array}} \times 100\%$$

For example, when $H_2(g)$ burns in $O_2(g)$, the sole product is H_2O. All the atoms of the reactants appear in the product and the atom economy is 100%, as implied by the equation $2\ H_2(g) + O_2(g) \longrightarrow 2\ H_2O(l)$. For the Raschig process described in the Focus On feature for Chapter 4 on www.masteringchemistry.com,
(a) what is the theoretical maximum AE for the synthesis of hydrazine (equation 4B)?
(b) Why is the actual AE less than that calculated in part (a)?
(c) Explain why substituting acetone for water improves the AE.
(d) Propose a reaction for the synthesis of hydrazine that would have a theoretical AE of 100%.

131. Baking soda, $NaHCO_3$, is made from soda ash, a common name for sodium carbonate. The soda ash is obtained in two ways. It can be manufactured in a process in which carbon dioxide, ammonia, sodium chloride, and water are the starting materials. Alternatively, it is mined as a mineral called *trona* (left photo). Whether the soda ash is mined or manufactured, it is dissolved in water and carbon dioxide is bubbled through the solution. Sodium bicarbonate precipitates from the solution.

As a chemical analyst you are presented with two samples of sodium bicarbonate—one from the manufacturing process and the other derived from trona. You are asked to determine which is purer and are told that the impurity is sodium carbonate. You decide to treat the samples with just sufficient hydrochloric acid to convert all the sodium carbonate and bicarbonate to sodium chloride, carbon dioxide, and water. You then precipitate silver chloride in the reaction of sodium chloride with silver nitrate. A 6.93 g sample of baking soda derived from trona gave 11.89 g of silver chloride. A 6.78 g sample from manufactured sodium carbonate gave 11.77 g of silver chloride. Which sample is purer, that is, which has the greater mass percent $NaHCO_3$?

Trona
$Na_2CO_3 \cdot NaHCO_3 \cdot 2H_2O$

Self-Assessment Exercises

132. In your own words, define or explain these terms or symbols.

(a) $\xrightarrow{\Delta}$ **(b)** (aq)

(c) stoichiometric coefficient **(d)** overall equation

133. Briefly describe **(a)** balancing a chemical equation; **(b)** preparing a solution by dilution; **(c)** determining the limiting reactant in a reaction.

134. Explain the important distinctions between **(a)** chemical formula and chemical equation; **(b)** stoichiometric coefficient and stoichiometric factor; **(c)** solute and solvent; **(d)** actual yield and percent yield; **(e)** consecutive and simultaneous reactions.

135. When the equation below is balanced, the correct set of stoichiometric coefficients is **(a)** 1, 6 $\longrightarrow$ 1, 3, 4; **(b)** 1,4 $\longrightarrow$ 1, 2, 2; **(c)** 2, 6 $\longrightarrow$ 2, 3, 2; **(d)** 3, 8 $\longrightarrow$ 3, 4, 2.

$$? \, Cu(s) + ? \, HNO_3(aq) \longrightarrow ? \, Cu(NO_3)_2(aq) + ? \, H_2O(l) + ? \, NO(g)$$

136. A reaction mixture contains 1.0 mol $CaCN_2$ (calcium cyanamide) and 1.0 mol H_2O. The maximum number of moles of NH_3 produced is **(a)** 3.0; **(b)** 2.0; **(c)** between 1.0 and 2.0; **(d)** less than 1.0.

$$CaCN_2(s) + 3\,H_2O(l) \longrightarrow CaCO_3 + 2\,NH_3(g)$$

137. Consider the chemical equation below. What is the maximum number of moles of K_2SO_4 that can be obtained from a reaction mixture containing 5.0 moles each of $KMnO_4$, KI, and H_2SO_4? **(a)** 3.0 mol; **(b)** 3.8 mol; **(c)** 5.0 mol; **(d)** 6.0 mol; **(e)** 15 mol.

$$2\,KMnO_4 + 10\,KI + 8\,H_2SO_4 \longrightarrow 6\,K_2SO_4 + 2\,MnSO_4 + 5\,I_2 + 8\,H_2O$$

138. In the decomposition of silver(I) carbonate to form metallic silver, carbon dioxide gas, and oxygen gas, **(a)** one mol of oxygen gas is formed for every 2 mol of carbon dioxide gas; **(b)** 2 mol of silver metal is formed for every 1 mol of oxygen gas; **(c)** equal numbers of moles of carbon dioxide and oxygen gases are produced; **(d)** the same number of moles of silver metal are formed as of the silver(I) carbonate decomposed.

139. To obtain a solution that is 1.00 M $NaNO_3$, you should prepare **(a)** 1.00 L of aqueous solution containing 100 g $NaNO_3$; **(b)** 1 kg of aqueous solution containing 85.0 g $NaNO_3$; **(c)** 5.00 L of aqueous solution containing 425 g $NaNO_3$; **(d)** an aqueous solution containing 8.5 mg $NaNO_3$/mL.

140. To prepare a solution that is 0.50 M KCl starting with 100.0 mL of 0.40 M KCl, you should **(a)** add 20.0 mL of water; **(b)** add 0.075 g KCl; **(c)** add 0.10 mol KCl; **(d)** evaporate 20.0 mL of water.

141. An aqueous solution that is 5.30% LiBr by mass has a density of 1.040 g/mL. What is the molarity of this solution? **(a)** 0.563 M; **(b)** 0.635 M; **(c)** 0.0635 M; **(d)** 0.0563 M; **(e)** 12.0 M.

142. In the reaction of 2.00 mol CCl_4 with an excess of HF, 1.70 mol CCl_2F_2 is obtained.

$$CCl_4 + 2\,HF \longrightarrow CCl_2F_2 + 2\,HCl$$

(a) The theoretical yield is 1.70 mol CCl_2F_2.
(b) The theoretical yield is 1.00 mol CCl_2F_2.
(c) The theoretical yield depends on how large an excess of HF is used.
(d) The percent yield is 85%.

143. The incomplete combustion of gasoline produces CO(g) as well as CO_2(g). Write an equation for **(a)** the complete combustion of the gasoline component octane, C_8H_{18}(l), and **(b)** incomplete combustion of octane with 25% of the carbon appearing as CO(g).

144. The minerals calcite, $CaCO_3$, magnesite, $MgCO_3$, and dolomite, $CaCO_3 \cdot MgCO_3$, decompose when strongly heated to form the corresponding metal oxide(s) and carbon dioxide gas. A 1.000-g sample known to be one of the three minerals was strongly heated and 0.477 g CO_2 was obtained. Which of the three minerals was it?

145. A 1.000 g sample of a mixture of CH_4 and C_2H_6 is analyzed by burning it completely in O_2, yielding 2.776 g CO_2. What is the percentage by mass of CH_4 in the mixture? **(a)** 93%; **(b)** 82%; **(c)** 67% ; **(d)** 36%; **(e)** less than 36%.

146. Nitric acid, HNO_3, can be manufactured from ammonia, NH_3, by using the three reactions shown below.

Step 1: $4\,NH_3(g) + 5\,O_2(g) \rightarrow 4\,NO(g) + 6\,H_2O(l)$

Step 2: $2\,NO(g) + O_2(g) \rightarrow 2\,NO_2(g)$

Step 3: $3\,NO_2(g) + H_2O(l) \rightarrow 2\,HNO_3(aq) + NO(g)$

What is the maximum number of moles of HNO_3 that can be obtained from 4.00 moles of NH_3? (Assume that the NO produced in step 3 is not recycled back into step 2.) **(a)** 1.33 mol; **(b)** 2.00 mol; **(c)** 2.67 mol; **(d)** 4.00 mol; **(e)** 6.00 mol.

147. Appendix E describes a useful study aid known as concept mapping. Using the method presented in Appendix E, construct a concept map relating the topics found in Sections 4-3, 4-4, and 4-5.

5

Introduction to Reactions in Aqueous Solutions

When clear, colorless aqueous solutions of cobalt(II) chloride and sodium hydroxide are mixed, a blue cloud of solid cobalt(II) hydroxide is formed. Such precipitation reactions are one of the three types of reactions considered in this chapter.

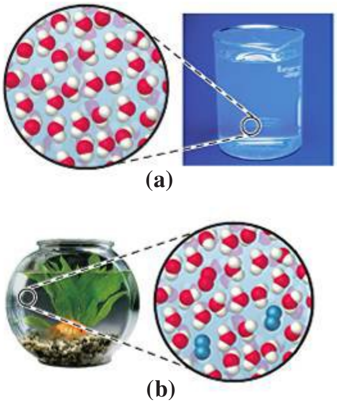
5-5 Balancing Oxidation–Reduction Equations
5-6 Oxidizing and Reducing Agents
5-7 Stoichiometry of Reactions in Aqueous Solutions: Titrations

Most reactions in the general chemistry laboratory are carried out in aqueous solutions—solutions for which water is the solvent. Aqueous solutions provide a convenient way of bringing together accurately measured amounts of reactants, and, not surprisingly, aqueous solutions feature prominently in many methods of chemical analysis. In this chapter, we will explore three different classes of reactions that occur in aqueous solutions—precipitation, acid–base, and oxidation–reduction reactions—with the goal of understanding the nature of the substances involved, the changes that occur in these substances, and the way each reaction can be used in the laboratory for analyzing samples.

Precipitation, the formation of a solid when solutions are mixed, is probably the most common evidence of a chemical reaction that general chemistry students see. A practical application of precipitation is in determining the presence of certain ions in solution. If, for example, we are uncertain whether the clear, colorless liquid in an unlabeled bottle is a barium nitrate or a barium chloride solution, we can easily find out by adding a few drops of silver nitrate solution to a small sample of the liquid. If a white solid forms, the sample is a barium chloride solution; if nothing happens, it is barium nitrate. The Ag^+ from the silver nitrate and the Cl^- from the barium chloride combine to produce an insoluble precipitate of AgCl(s). Precipitation reactions are the first reaction type we will study in this chapter. $Mg(OH)_2(s)$ is insoluble in water but soluble in hydrochloric acid, HCl(aq), as a result of an acid–base reaction. This is the reaction by which milk of magnesia neutralizes excess stomach acid. Magnesium hydroxide is a base, and acid–base reactions are the second class of reactions presented in this chapter. The third class of reactions is oxidation–reduction reactions, which are found in all aspects of life, from reactions in organisms to processes for manufacturing chemicals, to such practical matters as bleaching fabrics, purifying water, and destroying toxic chemicals.



▲ FIGURE 5-1
Molecular view of water and an aqueous solution of air
(a) Water molecules (red and white) are in close proximity in liquid water. **(b)** Dissolved oxygen (red) and nitrogen (blue) molecules are far apart, separated by water molecules.

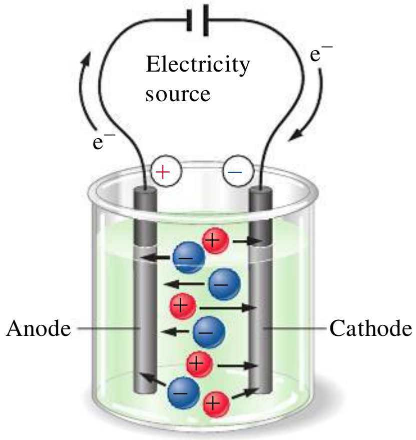
5-1 The Nature of Aqueous Solutions

Let's try to form a mental image of a solution at the molecular level. The solvent molecules, which are rather tightly packed, greatly outnumber all other molecules. Water is the solvent in an aqueous solution, and our mental image of water might look something like Figure 5-1(a). Solute particles—molecules or ions—are present in much smaller number and are randomly distributed among the solvent molecules. Our mental image of an aqueous solution of air might look something like Figure 5-1(b).

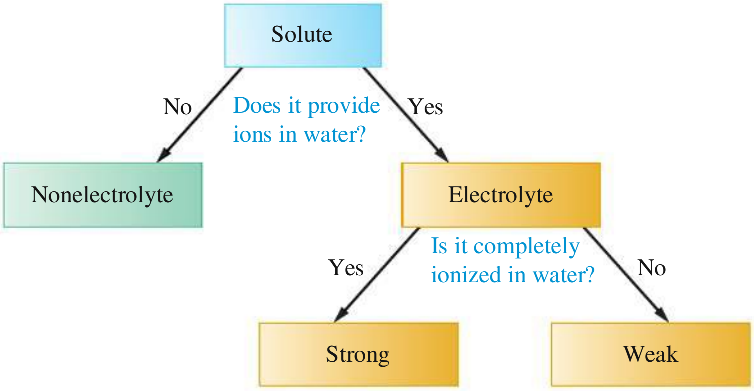
Because we will encounter aqueous solutions of ions throughout this chapter, it is useful to examine the nature of such solutions in a bit more detail. An important characteristic of an aqueous solution of ions is that it will conduct electricity, provided the concentration of ions is not too low. An aqueous solution of ions conducts electricity because the ions move essentially independently of each other, each one carrying a certain quantity of charge. (In a metallic conductor, such as copper or tungsten, electrons carry the charge.) The manner in which ions conduct electric current is suggested by Figure 5-2.

Whether or not an aqueous solution is a conductor of electricity depends on the nature of the solute(s). Pure water contains so few ions that it does not conduct electric current. However, some solutes produce ions in solution, thereby making the solution an electrical conductor. Solutes that provide ions when dissolved in water are called **electrolytes**. Solutes that that do not provide ions in water are called **nonelectrolytes**. All electrolytes provide ions in water but not all electrolytes are equal in their tendencies for providing ions. A **strong electrolyte** is a substance that is essentially *completely ionized* in aqueous solution. Stated another way, a strong electrolyte has a strong (or

▶ If a solute is *completely ionized*, then essentially all the dissolved solute exists as ions. If a solute is *partially ionized*, then only some (not all) of the solute molecules have been converted into ions.



▶ FIGURE 5-2
Conduction of electricity through a solution
Two graphite rods called electrodes are placed in a solution. The external source of electricity pulls electrons from one rod and forces them onto the other, creating a positive charge on one electrode and a negative charge on the other (right). In the solution, positive ions (cations) are attracted to the negative electrode, the *cathode*; negative ions (anions) are attracted to the positive electrode, the *anode*. Thus, electric charge is carried through the solution by the migration of ions. Other important aspects of electrical conductivity are discussed in Chapter 20.



Solute
Does it provide ions in water?
No
Yes
Nonelectrolyte
Electrolyte
Is it completely ionized in water?
Yes
No
Strong
Weak

◀ FIGURE 5-3
A classification scheme for solutes

high) tendency for providing ions. A **weak electrolyte** is a substance that is only *partially ionized* in aqueous solution. A weak electrolyte has a weak (or small) tendency for providing ions. One scheme for classifying solutes is summarized in Figure 5-3.

With the apparatus depicted in Figure 5-4, we can detect the presence of ions in an aqueous solution by measuring how well the solution conducts electricity. We can make one of three possible observations:

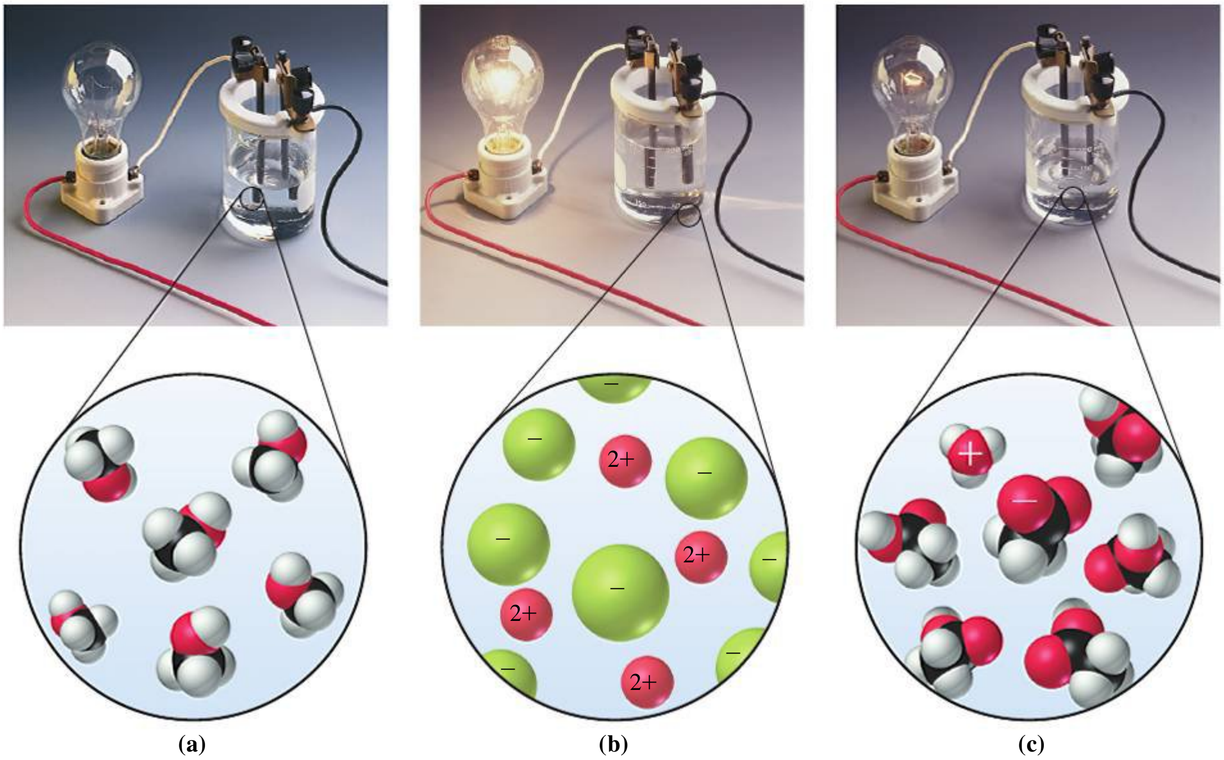
- *The lamp fails to light up* (Fig. 5-4a). Conclusion: no ions are present (or if some are present, their concentration is extremely low). The solution is either a solution of a nonelectrolyte or a very dilute solution of an electrolyte. Methanol, CH_3OH, is an example of a solute that does not provide ions in water; methanol is a *nonelectrolyte*. The microscopic view in Figure 5-4(a) is for an aqueous solution of methanol, and in this view we see that none of the CH_3OH molecules are ionized in water.
- *The lamp lights up brightly* (Fig. 5-4b). Conclusion: the concentration of ions in solution is high. The solute is a *strong electrolyte*. Magnesium chloride, $MgCl_2$, is an ionic compound that is completely ionized in water. The microscopic view in Figure 5-4(b) shows that an aqueous solution of $MgCl_2$ consists of Mg^{2+} and Cl^- ions in the solvent.
- *The lamp lights up only dimly* (Fig. 5-4c). Conclusion: ions are present in solution but the concentration of ions is low. The solution could be a solution of a weak electrolyte, such as acetic acid (CH_3COOH), or it could be a dilute—but not too dilute—solution of a strong electrolyte. The microscopic view in Figure 5-4(c) is for an aqueous solution of CH_3COOH and it shows that, in water, only some of the CH_3COOH molecules are ionized. An aqueous solution of CH_3COOH is only a weak conductor of electricity.

The following generalization is helpful when deciding whether a particular solute in an aqueous solution is most likely to be a nonelectrolyte, a strong electrolyte, or a weak electrolyte.

- Essentially all soluble ionic compounds and only a relatively few molecular compounds are strong electrolytes.
- Most molecular compounds are either nonelectrolytes or weak electrolytes.

KEEP IN MIND

that the electrical conductivity of a solution depends on two factors: (1) the total concentration of the electrolyte, and (2) the extent to which the electrolyte dissociates into ions. For example, a 0.001 M HCl(aq) solution will conduct electricity, but a 1×10^{-6} M HCl(aq) solution will not, even though every HCl molecule dissociates into H^+ and Cl^- ions in both solutions.



▲ FIGURE 5-4

Three types of electrolytes

In **(a)**, there are no ions present to speak of—only molecules. Methanol (methyl alcohol), CH_3OH, is a *nonelectrolyte* in aqueous solutions. In **(b)**, the solute is present almost entirely as individual ions. $MgCl_2$ is a *strong electrolyte* in aqueous solutions. In **(c)**, although most of the solute is present as molecules, a small fraction of the molecules ionize. CH_3COOH is a *weak electrolyte* in aqueous solution. The CH_3COOH molecules that ionize produce acetate ions CH_3COO^- and H^+ ions, and the H^+ ions attach themselves to water molecules to form hydronium ions, H_3O^+.

KEEP IN MIND

that the solvent molecules are densely packed. In such diagrams as Figure 5-4, we will often show the solvent as a uniformly colored background and depict only the solute particles.

Now let us consider how best to represent these three types of substances in chemical equations. For water-soluble $MgCl_2$, an ionic compound, we can write

$$MgCl_2(aq) \longrightarrow Mg^{2+}(aq) + 2\,Cl^-(aq)$$

This equation means that, in the presence of water, formula units of $MgCl_2$ are dissociated into the separate ions. The best representation of $MgCl_2(aq)$, then, is $Mg^{2+}(aq) + 2\,Cl^-(aq)$.

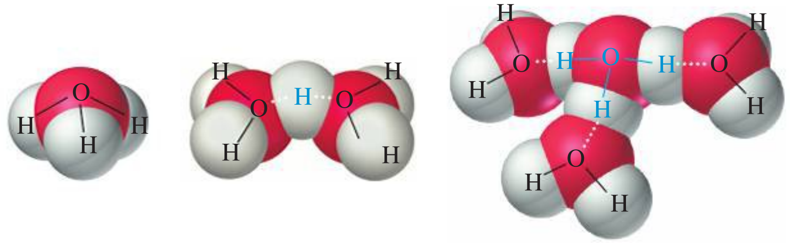
Hydrogen chloride, HCl, is an example of a molecular compound that is a strong electrolyte. When HCl dissolves in water, the following reaction occurs:

$$HCl(aq) \longrightarrow H^+(aq) + Cl^-(aq)$$

The best representation of hydrochloric acid, HCl(aq), is $H^+(aq) + Cl^-(aq)$.

▶ The International Union of Pure and Applied Chemistry (IUPAC) has recommended that the H_3O^+, ion be referred to as the *oxonium* ion. However, this recommendation has not yet been universally adopted by chemists.

The hydrogen cation H^+ is an interesting and important species that has been the subject of intensive research. The ion H^+—a bare proton—is a small particle that interacts with the water molecules surrounding it. The simple hydrogen ion, H^+, does not exist in aqueous solutions. Its actual form is as *hydronium ion*, H_3O^+, in which an H^+ ion is attached to an H_2O molecule. The hydronium ion, in turn, interacts with the water molecules surrounding it to



Hydronium ion H_3O^+

A hydrated proton $H_5O_2^+$

A hydrated proton $H_9O_4^+$

◀ FIGURE 5-5
The hydrated proton
The hydronium ion, H_3O^+, interacts with other water molecules through electrostatic attractions.

form additional species, such as $H_5O_2^+$, $H_7O_3^+$, $H_9O_4^+$ (shown in Figure 5-5) and many others. These interactions are called *hydration*, and the hydrated proton is represented as $H^+(aq)$, a shorthand notation. The interaction of the proton with a single water molecule is emphasized by using $H_3O^+(aq)$. The basis for these interactions will be discussed in Chapter 12 and employed extensively in Chapter 16.

For a solution of a weak electrolyte, the reaction that produces ions does not go to completion. In such solutions, only a fraction of the solute molecules in solution are ionized. Equations for solutions of this type are written with double arrows, as shown below.

$$CH_3COOH(aq) \rightleftharpoons H^+(aq) + CH_3COO^-(aq)$$

The double arrows indicate that the process is *reversible*—that is, while some CH_3COOH (acetic acid) molecules ionize, some H^+ and CH_3COO^- ions in solution recombine to form new CH_3COOH molecules. However, the relative proportions of ionized and nonionized (molecular) acid remain fixed. The predominant species is the molecule CH_3COOH, and the solution is best represented by $CH_3COOH(aq)$, *not* $H^+(aq) + CH_3COO^-(aq)$. If we could tag a particular CH_3COO group and watch it over time, we would sometimes see it as the ion CH_3COO^-, but most of the time it would be in a molecule, CH_3COOH.

KEEP IN MIND

that there are different ways to write the formulas for acetic acid. The molecular formula, $C_2H_4O_2$, makes no distinction between the types of H atoms; $HC_2H_3O_2$ emphasizes that there is only one ionizable H atom; and CH_3COOH and CH_3CO_2H emphasize that the ionizable H atom is part of the carboxyl group. Recall: The carboxyl group and carboxylic acids were introduced in Chapter 3.

For a nonelectrolyte, we simply write the molecular formula. Thus, for a solution of methanol in water, we would write $CH_3OH(aq)$.

With this new information about the nature of aqueous solutions, we can introduce a useful notation for solution concentrations. In a solution that is 0.0050 M $MgCl_2$, we assume that the $MgCl_2$ is completely dissociated into ions. Because there are two Cl^- ions for every Mg^{2+} ion, the solution is 0.0050 M Mg^{2+} but 0.0100 M Cl^-. Better still, let us introduce a special symbol for the concentration of a species in solution—the bracket symbol [ ]. The statement $[Mg^{2+}] = 0.0050$ M means that the concentration of the species within the brackets—that is, Mg^{2+}—is 0.0050 mol/L. Thus,

$$\textit{in } 0.0050\ M\ MgCl_2\text{:}\quad [Mg^{2+}] = 0.0050\ \text{M}; [Cl^-] = 0.0100\ \text{M}; [MgCl_2] = 0\ \text{M}$$

Although we do not usually write expressions like $[MgCl_2] = 0$, it is done here to emphasize that there is essentially no undissociated $MgCl_2$ in the solution.*

Example 5-1 shows how to calculate the concentrations of ions in a strong electrolyte solution.

---

*To say that a strong electrolyte is completely dissociated into individual ions in aqueous solution is a good approximation but somewhat of an oversimplification. Some of the cations and anions in solution may become associated into units called *ion pairs*. Generally, though, at the low solution concentrations we will be using, assuming complete dissociation will not seriously affect our results.

EXAMPLE 5-1 Calculating Ion Concentrations in a Solution of a Strong Electrolyte

What are the aluminum and sulfate ion concentrations in 0.0165 M $Al_2(SO_4)_3$?

Analyze

The solute is a strong electrolyte. Thus, it dissociates completely in water. First, we write a balanced chemical equation for the dissociation of $Al_2(SO_4)_3(aq)$, and then set up stoichiometric factors to relate Al^{3+} and SO_4^{2-} to the molarity of $Al_2(SO_4)_3$.

Solve

The dissociation of $Al_2(SO_4)_3$ is represented by the equation below.

$$Al_2(SO_4)_3(s) \xrightarrow{H_2O} 2\,Al^{3+}(aq) + 3\,SO_4^{2-}(aq)$$

The stoichiometric factors, shown in blue in the following equations, are derived from the fact that 1 mol $Al_2(SO_4)_3$ produces 2 mol Al^{3+} and 3 mol SO_4^{2-}.

$$[Al^{3+}] = \frac{0.0165\text{ mol }Al_2(SO_4)_3}{1\text{ L}} \times \frac{2\text{ mol }Al^{3+}}{1\text{ mol }Al_2(SO_4)_3} = \frac{0.0330\text{ mol }Al^{3+}}{1\text{ L}}$$

$$= 0.0330\text{ M}$$

$$[SO_4^{2-}] = \frac{0.0165\text{ mol }Al_2(SO_4)_3}{1\text{ L}} \times \frac{3\text{ mol }SO_4^{2-}}{1\text{ mol }Al_2(SO_4)_3} = \frac{0.0495\text{ mol }SO_4^{2-}}{1\text{ L}}$$

$$= 0.0495\text{ M}$$

Assess

For a strong electrolyte, the concentrations of the ions will always be integer multiples of the electrolyte molarity. For example, in 0.0165 M $MgCl_2$, we have $[Mg^{2+}] = 1 \times 0.0165$ M and $[Cl^-] = 2 \times 0.0165$ M.

PRACTICE EXAMPLE A: The chief ions in seawater are Na^+, Mg^{2+}, and Cl^-. Seawater is approximately 0.438 M NaCl and 0.0512 M $MgCl_2$. What is the molarity of Cl^-—that is, the total $[Cl^-]$—in seawater?

PRACTICE EXAMPLE B: A water treatment plant adds fluoride ion to the water to the extent of 1.5 mg F^-/L.

(a) What is the molarity of fluoride ion in this water?

(b) If the fluoride ion in the water is supplied by calcium fluoride, what mass of calcium fluoride is present in 1.00×10^6 L of this water?

5-1 CONCEPT ASSESSMENT

(1) Which solution is the best electrical conductor? **(a)** 0.50 M CH_3COCH_3; **(b)** 0.50 M CH_3CH_2OH; **(c)** 1.00 M $CH_2OHCHOHCH_2OH$; **(d)** 0.050 M CH_3COOH; **(e)** 0.025 M $RbNO_3$.

(2) Which solution has the highest total molarity of ions? **(a)** 0.008 M $Ba(OH)_2$; **(b)** 0.010 M KI; **(c)** 0.011 M CH_3COOH; **(d)** 0.030 M $HOCH_2CH_2OH$; **(e)** 0.004 M $Al_2(SO_4)_3$?

5-2 Precipitation Reactions

Some metal salts, such as NaCl, are quite soluble in water, while others, such as AgCl, are not very soluble at all. In fact, so little AgCl dissolves in water that this compound is generally considered to be *insoluble*. Precipitation reactions occur when certain cations and anions combine to produce an insoluble ionic solid called a **precipitate**. One laboratory use of precipitation reactions is in identifying the ions present in a solution, as shown in Figure 5-6. In industry, precipitation reactions are used to manufacture numerous chemicals. In the extraction of magnesium metal from seawater, for instance, the first step is to precipitate Mg^{2+} as $Mg(OH)_2(s)$. In this section, the objective is to represent precipitation reactions by chemical equations and to apply some simple rules for predicting precipitation reactions.

Net Ionic Equations

The reaction of silver nitrate and sodium iodide in an aqueous solution yields sodium nitrate in solution and a pale yellow or cream-colored precipitate of silver iodide, as shown in Figure 5-7. Applying the principles of equation writing from Chapter 4, we can write

$$AgNO_3(aq) + NaI(aq) \longrightarrow AgI(s) + NaNO_3(aq) \qquad \textbf{(5.1)}$$

You might note a contradiction, however, between equation (5.1) and something we learned earlier in this chapter. In their aqueous solutions, the soluble ionic compounds $AgNO_3$, NaI, and $NaNO_3$—all *strong* electrolytes—should be represented by their separate ions.

$$Ag^+(aq) + NO_3^-(aq) + Na^+(aq) + I^-(aq) \longrightarrow AgI(s) + Na^+(aq) + NO_3^-(aq) \qquad \textbf{(5.2)}$$

We might say that equation (5.1) is the "whole formula" form of the equation, whereas equation (5.2) is the "ionic" form. Notice also that in equation (5.2) $Na^+(aq)$ and $NO_3^-(aq)$ appear on both sides of the equation. These ions are not reactants; they go through the reaction unchanged. We call them **spectator ions**. If we eliminate the spectator ions, all that remains is the net ionic equation:

$$Ag^+(aq) + I^-(aq) \longrightarrow AgI(s) \qquad \textbf{(5.3)}$$

A **net ionic equation** is an equation that includes only the actual participants in a reaction, with each participant denoted by the symbol or formula that best represents it. Symbols are written for individual ions, such as $Ag^+(aq)$, and whole formulas are written for insoluble solids, such as AgI(s). Because net ionic equations include electrically charged species—ions—a net ionic equation must be balanced both for the numbers of atoms of all types and for electric charge. The same net electric charge must appear on both sides of the equation. Throughout the remainder of this chapter, we will represent most chemical reactions in aqueous solution by net ionic equations.

Predicting Precipitation Reactions

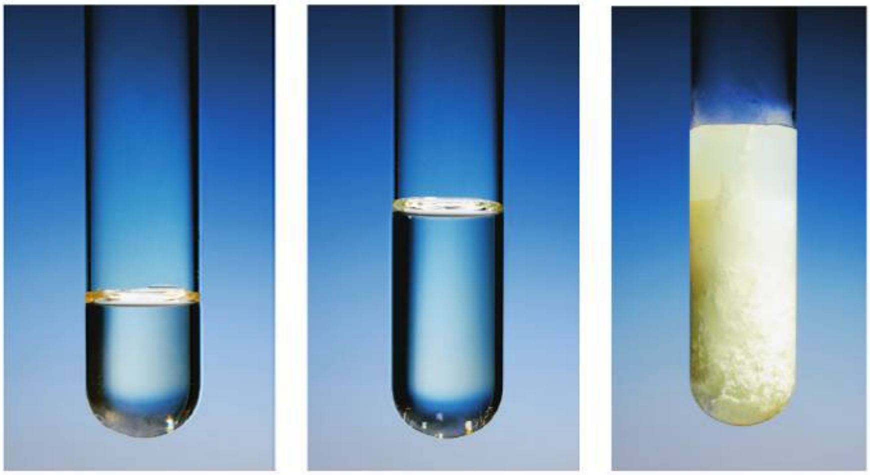
Suppose we are asked whether precipitation occurs when the following aqueous solutions are mixed.

$$AgNO_3(aq) + KBr(aq) \longrightarrow ? \qquad \textbf{(5.4)}$$

▲ FIGURE 5-6
Qualitative test for Cl^- in tap water
The test involves the addition of a few drops of $AgNO_3(aq)$ to tap water. The formation of a precipitate of AgCl(s) confirms the presence of Cl^-.

KEEP IN MIND

that although the insoluble solid consists of ions, we don't represent ionic charges in the whole formula. That is, we write AgI(s), not $Ag^+I^-(s)$.



(a) (b) (c)

◄ FIGURE 5-7
A precipitate of silver iodide
When an aqueous solution of $AgNO_3$ **(a)** is added to one of NaI **(b)**, insoluble pale yellow or cream-colored AgI(s) precipitates from solution **(c)**.

A good way to begin is to rewrite expression (5.4) in the ionic form.

$$\mathrm{Ag^+(aq) + NO_3^-(aq) + K^+(aq) + Br^-(aq) \longrightarrow ?} \qquad \textbf{(5.5)}$$

There are only two possibilities. Either some cation–anion combination leads to an insoluble solid—a precipitate—or no such combination is possible, and there is no reaction at all.

To predict what will happen without doing experiments, we need some information about which sorts of ionic compounds are water soluble and which are water insoluble. We expect the insoluble ones to form when the appropriate ions are mixed in solution. We don't have all-encompassing rules for predicting solubilities, but a few guidelines work for the majority of common ionic solutes. A concise form of these guidelines is presented in Table 5.1.

▶ In principle, all ionic compounds dissolve in water to some extent, though this may be very slight. For practical purposes, we consider a compound to be insoluble if the maximum amount that can dissolve is less than about 0.01 mol/L.

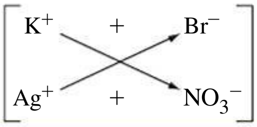
TABLE 5.1 Solubility Guidelines for Common Ionic Solids

Follow the lower-numbered guideline when two guidelines are in conflict. This leads to the correct prediction in most cases.

1. Salts of group 1 cations (with some exceptions for $\mathrm{Li^+}$) and the $\mathrm{NH_4^+}$ cation are soluble.
2. Nitrates, acetates, and perchlorates are soluble.
3. Salts of silver, lead, and mercury(I) are insoluble.
4. Chlorides, bromides, and iodides are soluble.
5. Carbonates, phosphates, sulfides, oxides, and hydroxides are insoluble (sulfides of group 2 cations and hydroxides of $\mathrm{Ca^{2+}}$, $\mathrm{Sr^{2+}}$, and $\mathrm{Ba^{2+}}$ are slightly soluble).
6. Sulfates are soluble except for those of calcium, strontium, and barium.

KEEP IN MIND

that when two ionic compounds form a solid precipitate, they do so by exchanging ions. In the formation of AgBr from KBr and $\mathrm{AgNO_3}$, the following exchange takes place.



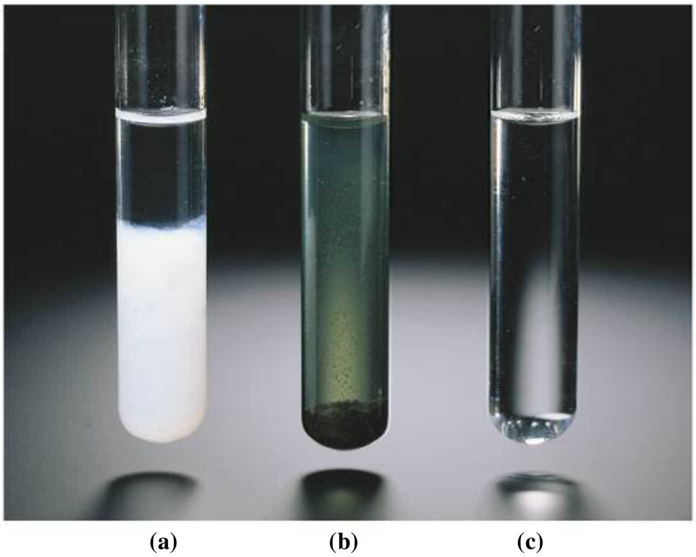
The guidelines from Table 5.1 are applied in the order listed, with the lower-numbered guideline taking precedence in cases of a conflict. According to these guidelines, AgBr(s) is insoluble in water (because rule 3 takes precedence over rule 4) and should precipitate, whereas $\mathrm{KNO_3(s)}$ is soluble (because of rule 1). Written as an ionic equation, expression (5.5) becomes

$$\mathrm{Ag^+(aq) + NO_3^-(aq) + K^+(aq) + Br^-(aq) \longrightarrow AgBr(s) + K^+(aq) + NO_3^-(aq)}$$

For the net ionic equation, we have

$$\mathrm{Ag^+(aq) + Br^-(aq) \longrightarrow AgBr(s)} \qquad \textbf{(5.6)}$$

The three predictions concerning precipitation reactions made in Example 5-2 are verified in Figure 5-8.



▶ FIGURE 5-8
Verifying the predictions made in Example 5-2
(a) When NaOH(aq) is added to $\mathrm{MgCl_2(aq)}$, a white precipitate of $\mathrm{Mg(OH)_2(s)}$ forms. **(b)** When colorless BaS(aq) is added to blue $\mathrm{CuSO_4(aq)}$, a dark precipitate forms. The precipitate is a mixture of white $\mathrm{BaSO_4(s)}$ and black CuS(s); a slight excess of $\mathrm{CuSO_4}$ remains in solution. **(c)** No reaction occurs when colorless $\mathrm{(NH_4)_2SO_4(aq)}$ is added to colorless $\mathrm{ZnCl_2(aq)}$.

EXAMPLE 5-2 Using Solubility Guidelines to Predict Precipitation Reactions

Predict whether a reaction will occur in each of the following cases. If so, write a net ionic equation for the reaction.

(a) $NaOH(aq) + MgCl_2(aq) \longrightarrow ?$
(b) $BaS(aq) + CuSO_4(aq) \longrightarrow ?$
(c) $(NH_4)_2SO_4(aq) + ZnCl_2(aq) \longrightarrow ?$

Analyze

All the compounds shown in **(a)**, **(b)**, and **(c)** are soluble and they provide ions in solution. By using the solubility guidelines in Table 5.1, determine whether the positive ions from one compound combine with the negative ions of the other to form soluble or insoluble compounds. If only soluble compounds are formed, then all ions remain in solution (no reaction). If an insoluble compound is formed, then the insoluble compound precipitates from the solution. The net ionic equation for the precipitation reaction is obtained by eliminating the spectator ions from the full ionic equation.

Solve

For each of **(a)**, **(b)** and **(c)**, apply the strategy described above.

(a) In aqueous solution, we get Na^+ and OH^- from NaOH and Mg^{2+} and Cl^- from $MgCl_2$. The combination of Na^+ and Cl^- gives NaCl, a soluble compound; thus, the Na^+ and Cl^- ions remain in solution. However, the Mg^{2+} and OH^- ions combine to produce $Mg(OH)_2$, an insoluble compound. The full, ionic equation is

$$2\,Na^+(aq) + 2\,OH^-(aq) + Mg^{2+}(aq) + 2\,Cl^-(aq) \longrightarrow Mg(OH)_2(s) + 2\,Na^+(aq) + 2\,Cl^-(aq)$$

With the elimination of spectator ions, we obtain

$$2\,OH^-(aq) + Mg^{2+}(aq) \longrightarrow Mg(OH)_2(s)$$

(b) In aqueous solution, we get Ba^{2+} and S^{2-} from BaS and Cu^{2+} and SO_4^{2-} from $CuSO_4$. The Ba^{2+} and SO_4^{2-} ions combine to form $BaSO_4$, an insoluble compound, and the Cu^{2+} and S^{2-} ions combine to form CuS, also an insoluble compound. The full ionic equation is

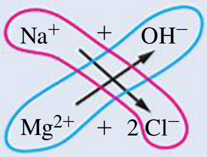
$$Ba^{2+}(aq) + S^{2-}(aq) + Cu^{2+}(aq) + SO_4^{2-}(aq) \longrightarrow BaSO_4(s) + CuS(s)$$

The equation above is also the net ionic equation because there are no spectator ions.

(c) We get NH_4^+, SO_4^{2-}, Zn^{2+}, and Cl^- ions in solution. Because all possible combinations of positive and negative ions lead to water soluble compounds, all of the ions remain in solution. No reaction occurs.

Assess

Problems of this type can also be solved by using a diagrammatic approach which is illustrated for part **(a)**.



$Mg(OH)_2$ is insoluble.

NaCl is soluble.

As you gain experience, you should be able to go directly to a net ionic equation without first having to write an ionic equation that includes spectator ions.

PRACTICE EXAMPLE A: Indicate whether a precipitate forms by completing each equation as a net ionic equation. If no reaction occurs, so state.

(a) $AlCl_3(aq) + KOH(aq) \longrightarrow ?$
(b) $K_2SO_4(aq) + FeBr_3(aq) \longrightarrow ?$
(c) $CaI_2(aq) + Pb(NO_3)_2(aq) \longrightarrow ?$

PRACTICE EXAMPLE B: Indicate through a net ionic equation whether a precipitate forms when the following compounds in aqueous solution are mixed. If no reaction occurs, so state.

(a) sodium phosphate + aluminum chloride ⟶ ?
(b) aluminum sulfate + barium chloride ⟶ ?
(c) ammonium carbonate + lead nitrate ⟶ ?

5-2 CONCEPT ASSESSMENT

Apply the solubility guidelines in Table 5.1 to predict whether each of the following solids is water soluble or insoluble. For which are the solubility guidelines inconclusive? **(a)** $Al_2(SO_4)_3$; **(b)** $Cr(OH)_3$; **(c)** K_3PO_4; **(d)** Li_2CO_3; **(e)** ZnS; **(f)** $Mg(MnO_4)_2$; **(g)** $AgClO_4$; **(h)** $CaSO_4$; **(i)** PbO.

5-1 ARE YOU WONDERING...

Whether an insoluble ionic compound, such as AgCl, is a strong electrolyte or a weak electrolyte?

Silver chloride, AgCl, is an ionic compound. When AgCl dissolves in water, it is 100% dissociated into Ag^+ and Cl^- ions; there are no AgCl ion pairs. If we focus only on the degree of dissociation, then AgCl, like HCl, is a strong electrolyte.

At one time, a strong electrolyte was defined in more practical terms as a substance that when dissolved in water, gives a solution that is a good conductor of electricity. Because AgCl has very low solubility in water, approximately 1×10^{-5} moles per liter, a solution of AgCl is not a good conductor of electricity.

Today, most chemists would argue that AgCl is a strong electrolyte (because it is 100% dissociated in aqueous solution) but some may argue that it is a weak electrolyte (because an aqueous solution of AgCl is not a good conductor of electricity).

Does it matter that chemists may not totally agree on whether AgCl should be called a strong electrolyte or a weak electrolyte? Not at all, because all chemists agree on the following facts: (1) AgCl is essentially 100% dissociated in water; (2) only a small amount of AgCl can be dissolved in water; and (3) an aqueous solution of AgCl is not a good conductor of electricity.

5-3 Acid–Base Reactions

Ideas about acids and bases (or alkalis) date back to ancient times. The word *acid* is derived from the Latin *acidus* (sour). *Alkali* (base) comes from the Arabic *al-qali*, referring to the ashes of certain plants from which alkaline substances can be extracted. The acid–base concept is a major theme in the history of chemistry. In this section, we emphasize the view proposed by Svante Arrhenius in 1884 but also introduce a more modern theory proposed in 1923 by Thomas Lowry and by Johannes Brønsted.

Acids

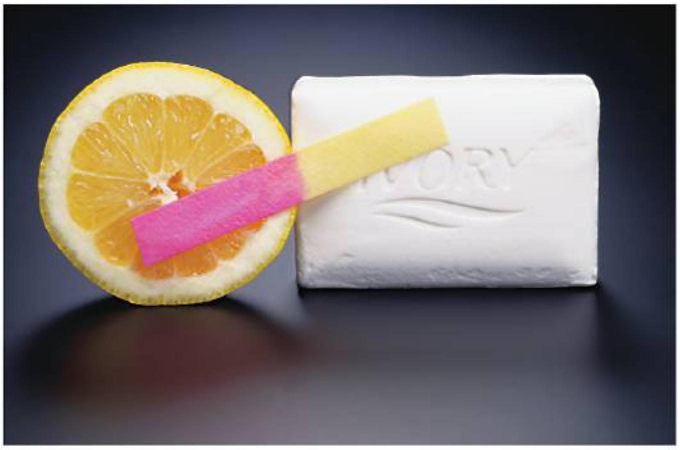
From a practical standpoint, acids can be identified by their sour taste, their ability to react with a variety of metals and carbonate minerals, and the effect they have on the colors of substances called *acid–base indicators*. Methyl red is an acid–base indicator that appears red in acidic environments and yellow otherwise (see Figure 5-9). From a chemist's point of view, however, an **acid** can be defined as a substance that provides hydrogen ions (H^+) in aqueous solution. This definition was first proposed by Svante Arrhenius in 1884.

Different acids exhibit different tendencies for producing H^+ ions in aqueous solution. **Strong acids** have a strong tendency for producing H^+ ions. Strong acids are molecular compounds that are almost completely ionized into $H^+(aq)$ and accompanying anions when in aqueous solution. Hydrogen chloride, HCl, and nitric acid, HNO_3, are examples of strong acids. When HCl dissolves in water, complete ionization into $H^+(aq)$ and $Cl^-(aq)$ occurs:

$$HCl(aq) \longrightarrow H^+(aq) + Cl^-(aq) \tag{5.7}$$

KEEP IN MIND

that $H^+(aq)$ actually represents a hydrated proton, that is, a proton attached to one H_2O molecule, as in H_3O^+, or to several H_2O molecules, as in $H_9O_4{}^+$.



◀ FIGURE 5-9
An acid, a base, and an acid–base indicator
The acidic nature of lemon juice is shown by the red color of the acid–base indicator *methyl red*. The basic nature of soap is indicated by the change in color of the indicator from red to yellow.

When HNO_3 dissolves in water, complete ionization into $H^+(aq)$ and $NO_3^-(aq)$ occurs. There are so few common strong acids that they make only a short list. The list of common strong acids is given in Table 5.2. It is imperative that you memorize this list.

Weak acids are molecular compounds that have a weak tendency for producing H^+ ions; weak acids are incompletely ionized in aqueous solution. The vast majority of acids are weak acids. The ionization of a weak acid is best described in terms of a reversible reaction that does not go to completion. As described on page 155, the ionization reaction for acetic acid, CH_3COOH, is

$$CH_3COOH(aq) \rightleftharpoons H^+(aq) + CH_3COO^-(aq) \qquad \textbf{(5.8)}$$

Equation (5.8) has the following interpretation: in aqueous solution, only some of the CH_3COOH molecules are converted into H^+ and CH_3COO^- ions. The fraction of molecules that ionize can be calculated, but the calculation is not simple. We will defer such calculations until Chapter 16.

Equations (5.7) and (5.8) are based on the Arrhenius theory of acids and bases, and these equations might lead you to think that acids simply fall apart into H^+ ions and the accompanying anions when they are dissolved in water. However, plenty of experimental evidence proves that this is not the case. In 1923, Johannes Brønsted in Denmark and Thomas Lowry in Great Britain independently proposed that the key process responsible for the properties of acids (and bases) was the transfer of an H^+ ion (a proton) from one substance to another. For example, when acids dissolve in water, H^+ ions are transferred from acid molecules to water molecules, as shown below for HCl and CH_3COOH.

$$HCl(aq) + H_2O(l) \longrightarrow H_3O^+(aq) + Cl^-(aq) \qquad \textbf{(5.9)}$$

$$CH_3COOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CH_3COO^-(aq) \qquad \textbf{(5.10)}$$

In equations (5.9) and (5.10), the acid molecules are acting as proton donors and the water molecules are acting as proton acceptors. According to the Brønsted-Lowry theory, an acid is a **proton donor**.

It is partly a matter of preference whether we include water as a reactant in the equation for the reaction that occurs when an acid is dissolved in water. Some chemists prefer to write the reaction without water as a reactant, as we did in equations (5.7) and (5.8), to eliminate the clutter of "extra" water molecules. If that is also your preference, then you must remember that the H^+ ion is not a free proton in solution but rather is firmly bound to a water molecule and exists as an H_3O^+ ion. The H_3O^+ ion is even further hydrated (see Figure 5-5). Many chemists prefer to include H_2O as a reactant, as we did in equations (5.9) and (5.10), to emphasize that the reactions actually involve the transfer of protons from acid molecules to water molecules.

TABLE 5.2 Common Strong Acids and Strong Bases

Acids	Bases
HCl	LiOH
HBr	NaOH
HI	KOH
$HClO_4$	RbOH
HNO_3	CsOH
H_2SO_4[a]	$Ca(OH)_2$
	$Sr(OH)_2$
	$Ba(OH)_2$

[a] H_2SO_4 ionizes in two distinct steps. It is a strong acid only in its first ionization step (see Section 16-6).

KEEP IN MIND

that a hydrogen atom consists of one proton and one electron. Therefore, a hydrogen ion, H^+, is simply a proton.

Bases

From a practical standpoint, we can identify bases through their bitter taste, slippery feel, and effect on the colors of acid–base indicators (Fig. 5-9). The Arrhenius definition of a **base** is a substance that produces hydroxide ions (OH^-) in aqueous solution. Consider a soluble ionic hydroxide, such as NaOH. In the solid state, this compound consists of Na^+ and OH^- ions. When the solid dissolves in water, the ions dissociate.

$$NaOH(aq) \longrightarrow Na^+(aq) + OH^-(aq)$$

The equation above indicates that NaOH(aq) is best represented as $Na^+(aq)$ plus $OH^-(aq)$.

A base that dissociates completely, or very nearly so, in aqueous solution is a **strong base**. As is true of strong acids, the number of common strong bases is small (see Table 5.2). They are primarily the hydroxides of group 1 and some group 2 metals. Memorize the list.

Certain substances produce OH^- ions by reacting with water, not just by dissolving in it. Such substances, for example, ammonia, are also bases.

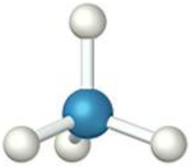
$$NH_3(aq) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq) \qquad \textbf{(5.11)}$$

NH_3 is a weak electrolyte; its reaction with water does not go to completion. A base that is incompletely ionized in aqueous solution is a **weak base**. Most basic substances are weak bases.

We can also examine equation (5.11) in terms of the Brønsted-Lowry theory, which focuses on the transfer of protons from one substance to another. According to this theory, a base is a **proton acceptor**. In equation (5.11), NH_3 behaves as a proton acceptor (a Brønsted-Lowry base) and H_2O behaves as a proton donor (a Brønsted-Lowry acid).

KEEP IN MIND

that $NH_4^+(aq)$ is formed by the transfer of a proton from an H_2O to a NH_3 molecule, and NH_4^+ interacts with water in much the same way as the hydronium ion does. A ball-and-stick model of the ammonium ion is shown below.



Ammonium ion

Acidic and Basic Solutions

We have seen that when dissolved in water, an acid produces H^+ ions and a base produces OH^- ions. However, experiment shows small numbers of H^+ and OH^- ions are present even in pure water. In pure water, the following reaction occurs to a limited extent, hence the use of a double arrow ($\rightleftharpoons$) rather than a single arrow ($\longrightarrow$).

$$H_2O(l) \rightleftharpoons H^+(aq) + OH^-(aq)$$

Careful measurements show that $[H^+]_{water} = [OH^-]_{water} = 1.0 \times 10^{-7}$ M at 25 °C. (The subscripts on the square brackets are there to emphasize that the values given for $[H^+]$ and $[OH^-]$ are for pure water only.) Because an acid produces H^+ ions in solution, we expect that a solution of acid at 25 °C will have $[H^+] > 1.0 \times 10^{-7}$ M. Such a solution is said to be *acidic*. An acidic solution has a greater concentration of H^+ ions than does pure water. A base produces OH^- ions, and so a solution of base will have $[OH^-] > 1.0 \times 10^{-7}$ M at 25 °C. Such a solution is said to be *basic*. These ideas are summarized below.

An *acidic* solution has $[H^+] > [H^+]_{water}$.
A *basic* solution has $[OH^-] > [OH^-]_{water}$.

The statements above can be expressed another way. An acidic solution has an excess of H^+ ions (compared with pure water), and a basic solution has an excess of OH^- ions. We will use these ideas in Section 5-5 and encounter them again in Chapter 16.

Neutralization

Perhaps the most significant property of acids and bases is the ability of each to cancel or neutralize the properties of the other. In a **neutralization reaction**, an acid and a base react to form water and an aqueous solution of an ionic compound called a **salt**. Thus, in molecular form,

$$\begin{array}{ccccccc} \mathrm{HCl(aq)} & + & \mathrm{NaOH(aq)} & \longrightarrow & \mathrm{NaCl(aq)} & + & \mathrm{H_2O(l)} \\ \text{(acid)} & + & \text{(base)} & \longrightarrow & \text{(salt)} & + & \text{(water)} \end{array}$$

Switching to the ionic form we write,

$$\underbrace{\mathrm{H^+(aq) + Cl^-(aq)}}_{\text{(acid)}} + \underbrace{\mathrm{Na^+(aq) + OH^-(aq)}}_{\text{(base)}} \longrightarrow \underbrace{\mathrm{Na^+(aq) + Cl^-(aq)}}_{\text{salt}} + \underbrace{\mathrm{H_2O(l)}}_{\text{water}}$$

When the spectator ions are eliminated, the net ionic equation shows the essential nature of the neutralization of a strong acid by a strong base: H^+ ions from the acid and OH^- ions from the base combine to form water.

$$\mathrm{H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)}$$

In a neutralization involving the weak base $NH_3(aq)$, we can think of H^+ from an acid combining directly with NH_3 molecules to form $NH_4{}^+$. The neutralization can be represented by an ionic equation, for example,

$$\underbrace{\mathrm{H^+(aq) + Cl^-(aq)}}_{\text{(acid)}} + \underbrace{\mathrm{NH_3(aq)}}_{\text{(base)}} \longrightarrow \underbrace{\mathrm{NH_4{}^+(aq) + Cl^-(aq)}}_{\text{(salt)}}$$

or by a net ionic equation

$$\mathrm{H^+(aq) + NH_3(aq) \longrightarrow NH_4{}^+(aq)}$$

All the neutralization reactions given above involve a strong acid or a strong base and all of them go essentially to completion, that is, until the limiting reagent is used up. Thus, we use a single arrow ($\longrightarrow$) rather than a double arrow ($\rightleftharpoons$) in the equations for these reactions.

◀ The formula of $NH_3(aq)$ is sometimes written as NH_4OH (ammonium hydroxide) and its ionization represented as

$$\mathrm{NH_4OH(aq) \rightleftharpoons NH_4^+(aq) + OH^-(aq)}$$

There is no hard evidence for the existence of NH_4OH, however, that is, in the sense of a discrete substance comprising $NH_4{}^+$ and OH^- ions. We will use only the formula $NH_3(aq)$.

Recognizing Acids and Bases

Acids contain *ionizable* hydrogen atoms, which are generally identified by the way in which the formula of an acid is written. Ionizable H atoms are separated from other H atoms in the formula either by writing them first in the molecular formula or by indicating where they are found in the molecule. Thus, there are two ways that we can show that one H atom in the acetic acid molecule is ionizable and the other three H atoms are not.

$$\underbrace{\mathrm{HC_2H_3O_2\ or\ CH_3COOH}}_{\text{acetic acid}}$$

In contrast to acetic acid, methane has four H atoms, but they are not ionizable. CH_4 is neither an acid nor a base.

A substance whose formula indicates a combination of OH^- ions with cations is generally a strong base (for example, NaOH). To identify a weak base, we usually need a chemical equation for the ionization reaction, as in equation (5.11). The main weak base we will work with at present is NH_3. Note that ethanol, CH_3CH_2OH, is not a base. The OH group is not present as OH^-, both in pure ethanol and in its aqueous solutions.

More Acid–Base Reactions

$Mg(OH)_2$ is a base because it contains OH^-, but this compound is quite insoluble in water. Its finely divided solid particles form a suspension in water that is the familiar milk of magnesia, used as an antacid. In this suspension, $Mg(OH)_2(s)$ does dissolve very slightly, producing some OH^- in solution. If an acid is added, H^+ from the acid combines with this OH^- to form water—neutralization occurs. More $Mg(OH)_2(s)$ dissolves to produce more OH^- in solution, which is neutralized by more H^+, and so on. In this way, the neutralization reaction results in the dissolving of otherwise insoluble $Mg(OH)_2(s)$. The net ionic equation for the reaction of $Mg(OH)_2(s)$ with a strong acid is

$$Mg(OH)_2(s) + 2\,H^+(aq) \longrightarrow Mg^{2+}(aq) + 2\,H_2O(l) \qquad \textbf{(5.12)}$$

$Mg(OH)_2(s)$ also reacts with a weak acid, such as acetic acid. In the net ionic equation, acetic acid is written in its molecular form. But remember that some H^+ and CH_3COO^- ions are always present in an acetic acid solution. The H^+ ions react with OH^- ions, as in reaction (5.12), followed by further ionization of CH_3COOH, more neutralization, and so on. If enough acetic acid is present, the $Mg(OH)_2$ will dissolve completely. The equation for the reaction is given below.

$$Mg(OH)_2(s) + 2\,CH_3COOH(aq) \longrightarrow Mg^{2+}(aq) + 2\,CH_3COO^-(aq) + 2\,H_2O(l) \qquad \textbf{(5.13)}$$

▲ FIGURE 5-10
Damage caused by acid rain
This marble statue has been eroded by acid rain. Marble consists primarily of $CaCO_3$. Acids react with and dissolve marble through the reaction described in equation (5.14).

Calcium carbonate, which is present in limestone and marble, is another water-insoluble solid that is soluble in strong and weak acids. Here the solid produces a low concentration of CO_3^{2-} ions, which combine with H^+ to form the weak acid H_2CO_3. This causes more of the solid to dissolve, and so on. Carbonic acid, H_2CO_3, is a very unstable substance that decomposes into H_2O and $CO_2(g)$. The net ionic equation for the reaction of $CaCO_3$ with an acid is given below.

$$CaCO_3(s) + 2\,H^+(aq) \longrightarrow Ca^{2+}(aq) + H_2O(l) + CO_2(g) \qquad \textbf{(5.14)}$$

Thus, a gas is given off when $CaCO_3(s)$ reacts with an acid and dissolves. The reaction represented by equation (5.14) is responsible for the erosion of marble statues by acid rain, such as the one shown in Figure 5-10. Equation (5.14) also shows that $CaCO_3(s)$ has the ability to neutralize acids. Not surprisingly, calcium carbonate, like magnesium hydroxide, is used as an antacid.

The Arrhenius definition recognizes only OH^- as a base, but when we reconsider acids and bases in more detail in Chapter 16, we will see that modern theories identify CO_3^{2-} and many other anions, including OH^-, as bases. Table 5.3 lists several common anions and one cation that produce gases in acid–base reactions.

TABLE 5.3 Some Common Gas-Forming Reactions

Ion	Reaction
HSO_3^-	$HSO_3^- + H^+ \longrightarrow SO_2(g) + H_2O(l)$
SO_3^{2-}	$SO_3^{2-} + 2\,H^+ \longrightarrow SO_2(g) + H_2O(l)$
HCO_3^-	$HCO_3^- + H^+ \longrightarrow CO_2(g) + H_2O(l)$
CO_3^{2-}	$CO_3^{2-} + 2\,H^+ \longrightarrow CO_2(g) + H_2O(l)$
S^{2-}	$S^{2-} + 2\,H^+ \longrightarrow H_2S(g)$
NH_4^+	$NH_4^+ + OH^- \longrightarrow NH_3(g) + H_2O(l)$

EXAMPLE 5-3 Writing Equations for Acid–Base Reactions

Write a net ionic equation to represent the reaction of **(a)** aqueous strontium hydroxide with nitric acid; **(b)** solid aluminum hydroxide with hydrochloric acid.

Analyze

The reactions are neutralization reactions, which means they are of the general form acid + base → salt + water. We can start with the whole formula equation, switch to the ionic equation, and then delete the spectator ions to arrive at the net ionic equation.

Solve

(a) $2\,HNO_3(aq) + Sr(OH)_2(aq) \longrightarrow Sr(NO_3)_2(aq) + 2\,H_2O(l)$

Ionic form:

$$2\,H^+(aq) + 2\,NO_3^-(aq) + Sr^{2+}(aq) + 2\,OH^-(aq) \longrightarrow Sr^{2+}(aq) + 2\,NO_3^-(aq) + 2\,H_2O(l)$$

Net ionic equation: Delete the spectator ions (Sr^{2+} and NO_3^-).

$$2\,H^+(aq) + 2\,OH^-(aq) \longrightarrow 2\,H_2O(l)$$

or, more simply,

$$H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$$

(b) $Al(OH)_3(s) + 3\,HCl(aq) \longrightarrow AlCl_3(aq) + 3\,H_2O(l)$

Ionic form:

$$Al(OH)_3(s) + 3\,H^+(aq) + 3\,Cl^-(aq) \longrightarrow Al^{3+}(aq) + 3\,Cl^-(aq) + 3\,H_2O(l)$$

Net ionic equation: Delete the spectator ion (Cl^-).

$$Al(OH)_3(s) + 3\,H^+(aq) \longrightarrow Al^{3+}(aq) + 3\,H_2O(l)$$

Assess

In part **(a)**, the net ionic equation is $H^+(aq) + OH^-(aq) \rightarrow H_2O(l)$, as is always the case when the neutralization reaction involves a soluble strong acid and a soluble strong base. In part **(b)**, the base was not soluble; thus, the net ionic equation includes a solid.

PRACTICE EXAMPLE A: Write a net ionic equation to represent the reaction of aqueous ammonia with propionic acid, CH_3CH_2COOH. Assume that the neutralization reaction goes to completion. What is the formula and name of the salt that results from this neutralization?

PRACTICE EXAMPLE B: Calcium carbonate is a major constituent of the hard water deposits found in teakettles and automatic coffeemakers. Vinegar, which is essentially a dilute aqueous solution of acetic acid, is commonly used to remove such deposits. Write a net ionic equation for the reaction that occurs. Assume that the neutralization reaction goes to completion.

5-3 CONCEPT ASSESSMENT

You are given the four solids, K_2CO_3, CaO, $ZnSO_4$, and $BaCO_3$, and three solvents, $H_2O(l)$, HCl(aq), and $H_2SO_4(aq)$. You are asked to prepare four solutions, each containing one of the four cations, that is, one with $K^+(aq)$, one with $Ca^{2+}(aq)$, and so on. Using water as your *first* choice, what solvent would you use to prepare each solution? Explain your choices.

5-4 Oxidation–Reduction Reactions: Some General Principles

Practical applications of oxidation–reduction reactions can be traced back thousands of years to the period in human culture when metal tools were first made. The metal needed to make tools was obtained by heating copper or iron ores, such as cuprite (Cu_2O) or hematite (Fe_2O_3), in the presence of carbon. Since

◀ An ore is a mineral from which a metal can be extracted. Many metal ores are oxides and the metals are obtained from their oxides by the removal of oxygen.

that time, iron has become the most widely used of all metals and it is produced in essentially the same way: by heating Fe_2O_3 in the presence of carbon in a blast furnace. A simplified chemical equation for the reaction is given below.

$$Fe_2O_3(s) + 3\,CO(g) \xrightarrow{\Delta} 2\,Fe(l) + 3\,CO_2(g) \qquad \textbf{(5.15)}$$

▶ In a blast furnace, carbon from the coke is converted to CO, which then reacts with Fe_2O_3.

In this reaction, we can think of the CO(g) as taking O atoms away from Fe_2O_3 to produce $CO_2(g)$ and the free element iron. A commonly used term to describe a reaction in which a substance gains O atoms is *oxidation*, and a reaction in which a substance loses O atoms is *reduction*. In reaction (5.15), CO(g) is oxidized and $Fe_2O_3(s)$ is reduced. Oxidation and reduction must always occur together, and such a reaction is called an **oxidation–reduction**, or **redox**, **reaction**. The oxygen in Fe_2O_3 can also be removed by igniting a finely divided mixture of Fe_2O_3 and Al. The reaction produces a spectacular display, shown in Figure 5-11, and releases a tremendous amount of heat, which causes the iron to melt. Mixtures of finely divided Fe_2O_3 and Al are used by railway workers to produce liquid iron for welding together iron railway tracks.

▶ Because it is easier to say, the term *redox* is often used instead of oxidation–reduction.

Definitions of oxidation and reduction based solely on the transfer of O atoms are too restrictive. By using broader definitions, many reactions in aqueous solution can be described as oxidation–reduction reactions, even when no oxygen is involved.

▲ FIGURE 5-11
Thermite reaction
Iron atoms of iron(III) oxide give up O atoms to Al atoms, producing Al_2O_3.

$$Fe_2O_3(s) + 2\,Al(s) \longrightarrow Al_2O_3(s) + 2\,Fe(l)$$

Oxidation State Changes

Suppose we rewrite equation (5.15) and indicate the oxidation states (O.S.) of the elements on both sides of the equation by using the rules listed on page 85.

$$\overset{+3}{Fe}_2\overset{-2}{O}_3 + 3\,\overset{+2}{C}\overset{-2}{O} \longrightarrow 2\,\overset{0}{Fe} + 3\,\overset{+4}{C}\overset{-2}{O}_2$$

The O.S. of oxygen is −2 everywhere it appears in this equation. That of iron (shown in red) changes. It *decreases* from +3 in Fe_2O_3 to 0 in the free element, Fe. The O.S. of carbon (shown in blue) also changes. It *increases* from +2 in CO to +4 in CO_2. In terms of oxidation state changes, in an oxidation process, the O.S. of some element increases; in a reduction process, the O.S. of some element decreases.

Even though we assess oxidation state changes by element, oxidation and reduction involve the entire species in which the element is found. Thus, for the reaction above, the whole compound Fe_2O_3 is reduced, not just the Fe atoms; and CO is oxidized, not just the C atom.

EXAMPLE 5-4 Identifying Oxidation–Reduction Reactions

Indicate whether each of the following is an oxidation–reduction reaction.

(a) $MnO_2(s) + 4\,H^+(aq) + 2\,Cl^-(aq) \longrightarrow Mn^{2+}(aq) + 2\,H_2O(l) + Cl_2(g)$

(b) $H_2PO_4^-(aq) + OH^-(aq) \longrightarrow HPO_4^{2-}(aq) + H_2O(l)$

Analyze

In each case, indicate the oxidation states of the elements on both sides of the equation, and look for changes.

Solve

(a) The O.S. of Mn decreases from +4 in MnO_2 to +2 in Mn^{2+}. MnO_2 is reduced to Mn^{2+}. The O.S. of O remains at −2 throughout the reaction, and that of H, at +1. The O.S. of Cl increases from −1 in Cl^- to 0 in Cl_2. Cl^- is oxidized to Cl_2. The reaction is an oxidation–reduction reaction.

(b) The O.S. of H is +1 on both sides of the equation. Oxygen remains at O.S. −2 throughout. The O.S. of phosphorus is +5 in $H_2PO_4^-$ and also +5 in HPO_4^{2-}. There are no changes in O.S. This is not an oxidation–reduction reaction. (It is, in fact, an acid–base reaction.)

Assess

Because many redox reactions involve H^+, OH^-, or insoluble ionic compounds, it is easy to confuse a redox reaction with an acid–base or a precipitation reaction. It is important that you remember the defining features of each type of reaction. Precipitation reactions involve the combination of ions in solution to produce an insoluble precipitate, acid–base reactions involve proton (H^+) transfer, and redox reactions involve electron transfer and changes in oxidation states.

PRACTICE EXAMPLE A: Identify whether each of the following is an oxidation–reduction reaction.

(a) $(NH_4)_2SO_4(aq) + Ba(NO_3)_2(aq) \longrightarrow BaSO_4(s) + 2\,NH_4NO_3(aq)$

(b) $2\,Pb(NO_3)_2(s) \longrightarrow 2\,PbO(s) + 4\,NO_2(g) + O_2(g)$

PRACTICE EXAMPLE B: Identify the species that is oxidized and the species that is reduced in the reaction below.

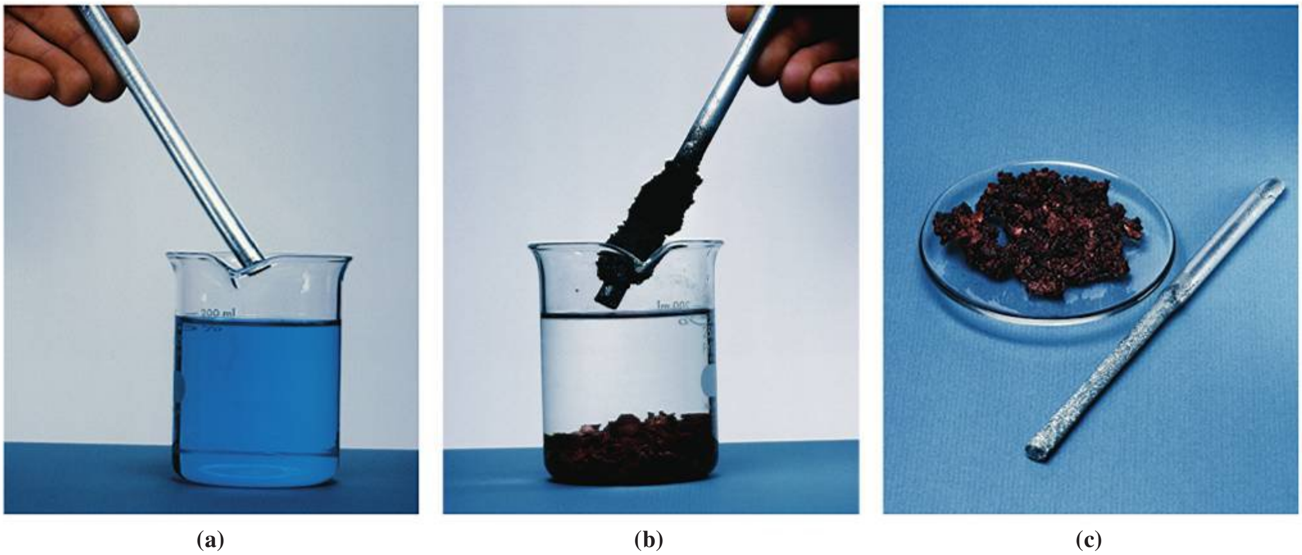
$$5\,VO^{2+}(aq) + MnO_4^-(aq) + H_2O(l) \longrightarrow 5\,VO_2^+(aq) + Mn^{2+}(aq) + 2\,H^+(aq)$$

Oxidation and Reduction Half-Reactions

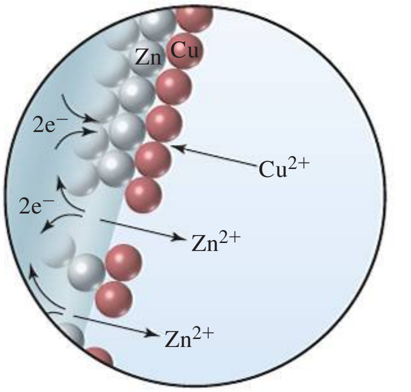
The reaction illustrated in Figure 5-12 is an oxidation–reduction reaction. The chemical equation for the reaction is given below.

$$Zn(s) + Cu^{2+}(aq) \longrightarrow Zn^{2+}(aq) + Cu(s)$$

We can show that the reaction is an oxidation–reduction reaction by evaluating changes in oxidation state, but there is another especially useful way to establish this. Think of the reaction as involving two **half-reactions** occurring at the same time—an oxidation and a reduction. The overall reaction is the



(a) (b) (c)



▲ FIGURE 5-12
An oxidation–reduction reaction
(a) A zinc rod above an aqueous solution of copper(II) sulfate. **(b)** Following immersion of the Zn rod in the $CuSO_4(aq)$ for several hours, the blue color of $Cu^{2+}(aq)$ disappears and a deposit of copper forms on the rod. In the microscopic view on the left, the gray spheres represent Zn atoms and the red spheres represent Cu atoms. In the reaction, Zn atoms lose electrons to the metal surface and enter the solution as Zn^{2+} ions. Cu^{2+} ions from the solution pick up electrons and deposit on the metal surface as atoms of solid copper. **(c)** The pitted zinc rod (providing evidence that zinc was consumed in a chemical reaction) and the collected copper metal.

sum of the two half-reactions. We can represent the half-reactions by half-equations and the overall reaction by an overall equation.

$$\text{Oxidation:} \quad Zn(s) \longrightarrow Zn^{2+}(aq) + 2\,e^- \tag{5.16}$$

$$\text{Reduction:} \quad Cu^{2+}(aq) + 2\,e^- \longrightarrow Cu(s) \tag{5.17}$$

$$\text{Overall:} \quad Zn(s) + Cu^{2+}(aq) \longrightarrow Zn^{2+}(aq) + Cu(s) \tag{5.18}$$

In half-reaction (5.16), Zn is oxidized—its oxidation state increases from 0 to +2. This change corresponds to a loss of two electrons by each zinc atom. In half-reaction (5.17), Cu^{2+} is reduced—its oxidation state decreases from +2 to 0. This change corresponds to the gain of two electrons by each Cu^{2+} ion. To summarize,

- **Oxidation** is a process in which the O.S. of some element *increases* as electrons are lost. Electrons appear on the *right* side of a half-equation.
- **Reduction** is a process in which the O.S. of some element *decreases* as electrons are gained. Electrons appear on the *left* side of a half-equation.
- Oxidation and reduction half-reactions must always occur together, and the total number of electrons associated with the oxidation must *equal* the total number associated with the reduction.

Redox reactions are similar to acid–base reactions in that both types of reactions involve the transfer of small, fundamental particles; protons are transferred in acid–base reactions and electrons are transferred in redox reactions. However, acid-base reactions are easily identified because the hydrogen atoms and protons (H^+) are shown explicitly in the balanced chemical equation. Redox reactions are much more difficult to identify because the electrons are "hidden." When we write out the half-equations for the oxidation and reduction processes, the electrons are shown explicitly and the key feature of a redox reaction, electron transfer, is emphasized.

Figure 5-13 and Example 5-5 suggest some fundamental questions about oxidation–reduction. For example,

- Why does Fe react with HCl(aq), displacing $H_2(g)$, whereas Cu does not?
- Why does Fe form Fe^{2+} and not Fe^{3+} in this reaction?

EXAMPLE 5-5 Representing an Oxidation–Reduction Reaction Through Half-Equations and an Overall Equation

Write equations for the oxidation and reduction processes that occur and the overall equation for the reaction of iron with hydrochloric acid solution to produce $H_2(g)$ and Fe^{2+}. The reaction is shown in Figure 5-13.

Analyze

The reactants are Fe(s) and HCl(aq), and the products are $H_2(g)$ and $FeCl_2(aq)$, a soluble ionic compound. In the reaction, the oxidation state of iron changes from 0 in Fe to +2 in $FeCl_2$, and the oxidation state of hydrogen changes from +1 in HCl to 0 in H_2. Thus, iron is oxidized and hydrogen is reduced.

Solve

The balanced chemical equations are as follows.

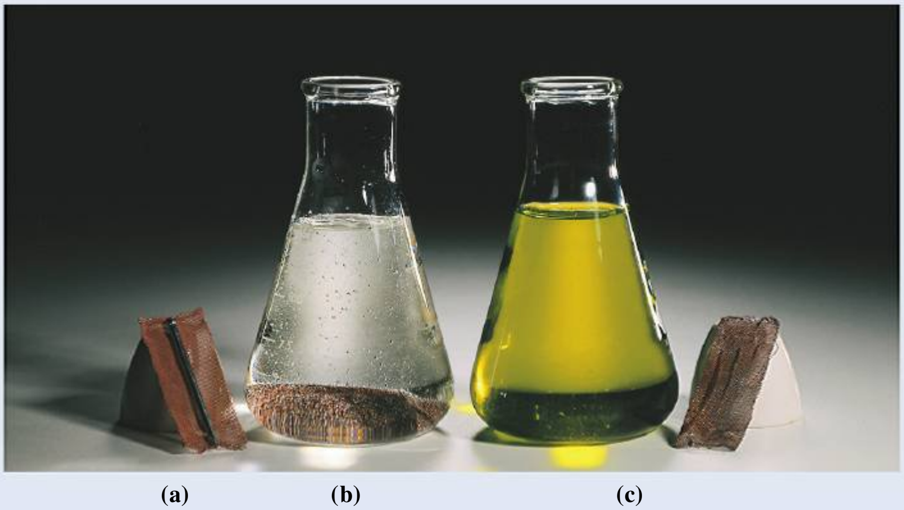
$$\text{Oxidation:} \quad Fe(s) \longrightarrow Fe^{2+}(aq) + 2\,e^-$$

$$\text{Reduction:} \quad 2\,H^+(aq) + 2\,e^- \longrightarrow H_2(g)$$

$$\text{Overall:} \quad Fe(s) + 2\,H^+(aq) \longrightarrow Fe^{2+}(aq) + H_2(g)$$

Assess

This example illustrates that iron dissolves in acid solution. Iron is a major component of steel and the reaction in this example contributes to the corrosion of steel that is exposed to air and moisture. For example, H^+ ions from acid rain cause Fe atoms in steel to become oxidized to Fe^{2+} ions. The oxidation of iron creates small pits in the steel surface and leads to corrosion.



▲ FIGURE 5-13

Displacement of H^+ (aq) by iron—Example 5-5 illustrated

(a) An iron nail is wrapped in a piece of copper screen. **(b)** The nail and screen are placed in HCl(aq). Hydrogen gas is evolved as the nail reacts. **(c)** The nail reacts completely and produces $Fe^{2+}(aq)$, but the copper does not react.

PRACTICE EXAMPLE A: Represent the reaction of aluminum with hydrochloric acid to produce $AlCl_3(aq)$ and $H_2(g)$ by oxidation and reduction half-equations and an overall equation.

PRACTICE EXAMPLE B: Represent the reaction of chlorine gas with aqueous sodium bromide to produce liquid bromine and aqueous sodium chloride by oxidation and reduction half-equations and an overall equation.

Even now, you can probably see that the answers to these questions lie in the relative abilities of Fe and Cu atoms to give up electrons—to become oxidized. Fe gives up electrons more easily than does Cu; also, Fe is more readily oxidized to Fe^{2+} than it is to Fe^{3+}. We can give more complete answers after we develop specific criteria describing electron loss and gain in Chapter 20. For now, the information in Table 5.4 should be helpful. The table lists some common metals that react with acids to displace $H_2(g)$ and a few that do not. As noted in the table, most of the group 1 and 2 metals are so reactive that they will react with cold water to produce $H_2(g)$ and a solution of the metal hydroxide.

TABLE 5.4 Behavior of Some Common Metals with Nonoxidizing Acids[a]

React to Produce $H_2(g)$	Do Not React
Alkali metals (group 1)[b] Alkaline earth metals (group 2)[b] Al, Zn, Fe, Sn, Pb	Cu, Ag, Au, Hg

[a] A nonoxidizing acid (for example, HCl, HBr, HI) is one in which the only possible reduction half-reaction is the reduction of H^+ to H_2. Additional possibilities for metal–acid reactions are considered in Chapter 20.

[b] With the exception of Be and Mg, all group 1 and group 2 metals also react with cold water to produce $H_2(g)$; the metal hydroxide is the other product.

5-4 CONCEPT ASSESSMENT

Disregarding the fact that the equations below are not balanced, is it likely that either represents a reaction that could possibly occur? Explain.

(a) $MnO_4^-(aq) + Cr_2O_7^{2-}(aq) + H^+(aq) \longrightarrow MnO_2(s) + Cr^{3+}(aq) + H_2O(l)$

(b) $Cl_2(g) + OH^-(aq) \longrightarrow Cl^-(aq) + ClO_3^-(aq) + H_2O(l)$

5-5 Balancing Oxidation–Reduction Equations

▶ *Half-reaction* or *half-equation*, which is it? *Reaction* refers to the actual process. An *equation* is a notation we write out to indicate the formulas of the reactants and products, and their mole relationships. Many chemists refer to what we balance here as half-reactions but half-equation is more proper.

In a chemical reaction, atoms are neither created nor lost; they are simply rearranged. We used this idea in Chapter 4 to balance chemical equations by inspection. In a redox reaction, we have additional considerations. Electrons are transferred from one substance to another and so we must keep track of electrons and the charge that these electrons carry. Therefore, in balancing the chemical equation for a redox reaction, we focus equally on three factors: (1) the number of atoms of each type, (2) the number of electrons transferred, and (3) the total charges on reactants and products. We should point out, however, that if we balance the equation with respect to the number of atoms and the number of electrons transferred, then the equation is automatically balanced with respect to the total charges.

Because it is very challenging to deal with all three of these factors simultaneously, only a small proportion of oxidation–reduction equations can be balanced by simple inspection. To make this point clear, consider the following reactions, each of which appears to be balanced. The reactions are balanced with respect to the number of atoms of each type and the total charges on reactants and products, but not with respect to the number of electrons transferred.

▶ For brevity, the physical forms of reactants and products are not included in these equations. For all ions, as well as H_2O_2, the physical form is "(aq)." Of course, the physical forms of oxygen and water are $O_2(g)$ and $H_2O(l)$.

$$2\,MnO_4^- + H_2O_2 + 6\,H^+ \longrightarrow 2\,Mn^{2+} + 3\,O_2 + 4\,H_2O \qquad (5.19)$$

$$2\,MnO_4^- + 3\,H_2O_2 + 6\,H^+ \longrightarrow 2\,Mn^{2+} + 4\,O_2 + 6\,H_2O \qquad (5.20)$$

$$2\,MnO_4^- + 5\,H_2O_2 + 6\,H^+ \longrightarrow 2\,Mn^{2+} + 5\,O_2 + 8\,H_2O \qquad (5.21)$$

$$2\,MnO_4^- + 7\,H_2O_2 + 6\,H^+ \longrightarrow 2\,Mn^{2+} + 6\,O_2 + 10\,H_2O \qquad (5.22)$$

These are just a few of the "balanced" chemical equations we can write for the reaction. However, only one, equation (5.21), is properly balanced because it is the only one that is balanced with respect to the number of electrons transferred.

To balance the chemical equation for a redox reaction, we need to make use of a systematic approach that considers each of the relevant factors in turn. Although several methods are available, we emphasize one that focuses first on balancing separate half-equations and then on combining the two half-equations to obtain the overall chemical equation. The method is summarized below. An alternative method is described in Exercise 98.

The Half-Equation Method

The basic steps in this method of balancing a redox equation are as follows:

- Write and balance separate half-equations for oxidation and reduction.
- Adjust coefficients in the two half-equations so that the same number of electrons appear in each half-equation.
- Add together the two half-equations (canceling out electrons) to obtain the balanced overall equation.

TABLE 5.5 Balancing Equations for Redox Reactions in Acidic Aqueous Solutions by the Half-Equation Method: A Summary

- Write the equations for the oxidation and reduction half-reactions.
- In each half-equation
  - (1) Balance atoms of all the elements except H and O
  - (2) Balance oxygen by using H_2O
  - (3) Balance hydrogen by using H^+
  - (4) Balance charge by using electrons
- If necessary, equalize the number of electrons in the oxidation and reduction half-equations by multiplying one or both half-equations by appropriate integers.
- Add the half-equations, then cancel species common to both sides of the overall equation.
- Check that both numbers of atoms and charges balance.

This first step in this method actually involves several steps. A detailed description of the method is given in Table 5.5. The method is appropriate for reactions that occur in an acidic solution. Because an acidic solution contains an excess of H^+ ions, the method uses H^+ ions in balancing the half-equations.

EXAMPLE 5-6 Balancing the Equation for a Redox Reaction in an Acidic Solution

The reaction described by expression (5.23) below is used to determine the sulfite ion concentration present in wastewater from a papermaking plant. Use the half-equation method to obtain a balanced equation for this reaction in an acidic solution.

$$SO_3^{2-}(\text{aq}) + MnO_4^{-}(\text{aq}) \longrightarrow SO_4^{2-}(\text{aq}) + Mn^{2+}(\text{aq}) \tag{5.23}$$

Analyze

The reaction occurs in acidic aqueous solution. We can use the method summarized in Table 5.5 to balance it.

Solve

The O.S. of sulfur increases from +4 in SO_3^{2-} to +6 in SO_4^{2-}. The O.S. of Mn decreases from +7 in MnO_4^- to +2 in Mn^{2+}. Thus, SO_3^{2-} is oxidized and MnO_4^- is reduced.

Step 1. *Write skeleton half-equations based on the species undergoing oxidation and reduction.* The half-equations are

$$SO_3^{2-}(\text{aq}) \longrightarrow SO_4^{2-}(\text{aq})$$
$$MnO_4^{-}(\text{aq}) \longrightarrow Mn^{2+}(\text{aq})$$

Step 2. *Balance each half-equation for numbers of atoms, in this order:*

- atoms other than H and O
- O atoms, by adding H_2O with the appropriate coefficient
- H atoms, by adding H^+ with the appropriate coefficient

The other atoms (S and Mn) are already balanced in the half-equations. To balance O atoms, we add one H_2O molecule to the left side of the first half-equation and four to the right side of the second.

$$SO_3^{2-}(\text{aq}) + H_2O(\text{l}) \longrightarrow SO_4^{2-}(\text{aq})$$
$$MnO_4^{-}(\text{aq}) \longrightarrow Mn^{2+}(\text{aq}) + 4\,H_2O(\text{l})$$

To balance H atoms, we add two H^+ ions to the right side of the first half-equation and eight to the left side of the second.

$$SO_3^{2-}(\text{aq}) + H_2O(\text{l}) \longrightarrow SO_4^{2-}(\text{aq}) + 2\,H^{+}(\text{aq})$$
$$MnO_4^{-}(\text{aq}) + 8\,H^{+}(\text{aq}) \longrightarrow Mn^{2+}(\text{aq}) + 4\,H_2O(\text{l})$$

(continued)

Step 3. *Balance each half-equation for electric charge.* Add the number of electrons necessary to get the same electric charge on both sides of each half-equation. By doing this, you will see that the half-equation in which electrons appear on the right side is the *oxidation half-equation*. The other half-equation, with electrons on the left side, is the *reduction half-equation*.

Oxidation: $SO_3^{2-}(aq) + H_2O(l) \longrightarrow SO_4^{2-}(aq) + 2\,H^+(aq) + 2\,e^-$
(net charge on each side, −2)

Reduction: $MnO_4^-(aq) + 8\,H^+(aq) + 5\,e^- \longrightarrow Mn^{2+}(aq) + 4\,H_2O(l)$
(net charge on each side, +2)

Step 4. *Obtain the overall redox equation by combining the half-equations.* Multiply the oxidation half-equation by 5 and the reduction half-equation by 2. This results in $10\,e^-$ on each side of the overall equation. These terms cancel out. *Electrons must not appear in the final equation.*

Overall:

$$\begin{array}{l} 5\,SO_3^{2-}(aq) + 5\,H_2O(l) \longrightarrow 5\,SO_4^{2-}(aq) + 10\,H^+(aq) + \cancel{10\,e^-} \\ 2\,MnO_4^-(aq) + 16\,H^+(aq) + \cancel{10\,e^-} \longrightarrow 2\,Mn^{2+}(aq) + 8\,H_2O(l) \\ \hline 5\,SO_3^{2-}(aq) + 2\,MnO_4^-(aq) + 5\,H_2O(l) + 16\,H^+(aq) \longrightarrow \\ \qquad 5\,SO_4^{2-}(aq) + 2\,Mn^{2+}(aq) + 8\,H_2O(l) + 10\,H^+(aq) \end{array}$$

Step 5. *Simplify.* The overall equation should not contain the same species on both sides. Subtract $5\,H_2O$ from each side of the equation in step 4. This leaves $3\,H_2O$ on the right. Also subtract $10\,H^+$ from each side, leaving $6\,H^+$ on the left.

$$5\,SO_3^{2-}(aq) + 2\,MnO_4^-(aq) + 6\,H^+(aq) \longrightarrow 5\,SO_4^{2-}(aq) + 2\,Mn^{2+}(aq) + 3\,H_2O(l)$$

Step 6. *Verify.* Check the overall equation to ensure that it is balanced both for numbers of atoms and electric charge. For example, show that in the balanced equation from step 5, the net charge on each side of the equation is −6: $(5 \times 2-) + (2 \times 1-) + (6 \times 1+) = (5 \times 2-) + (2 \times 2+) = -6$.

Assess

The final check completed in step 6 gives us confidence that our result is correct. This is an important step; always take the time to complete it. It is also worth pointing out that, in this example, there was only one atom per formula that was oxidized or reduced. (Refer to the skeleton half-equations given in step 1.) Many students have difficulty balancing half-equations in which more than one atom per formula is oxidized or reduced, as is the case when $Cr_2O_7^{2-}$ is reduced to Cr^{3+}. Had we used $Cr_2O_7^{2-}$ instead of MnO_4^- in equation (5.23), the balanced chemical equation for the reaction would have been $3\,SO_3^{2-} + Cr_2O_7^{2-} + 8\,H^+ \rightarrow 3\,SO_4^{2-} + 2\,Cr^{3+} + 4\,H_2O$.

PRACTICE EXAMPLE A: Balance the equation for this reaction in acidic solution.

$$Fe^{2+}(aq) + MnO_4^-(aq) \longrightarrow Fe^{3+}(aq) + Mn^{2+}(aq)$$

PRACTICE EXAMPLE B: Balance the equation for this reaction in acidic solution.

$$UO^{2+}(aq) + Cr_2O_7^{2-}(aq) \longrightarrow UO_2^{2+}(aq) + Cr^{3+}(aq)$$

Balancing Redox Equations in a Basic Solution

To balance equations for redox reactions in a basic solution, a step or two must be added to the procedure used in Example 5-6. The problem is that in basic solution, OH^-, not H^+, must appear in the final balanced equation. (Recall that, in basic solutions, OH^- ions are present in excess.) Because both OH^- and H_2O contain H and O atoms, at times it is hard to decide on which side of the half-equations to put each one. One simple approach is to treat the reaction as though it were occurring in an acidic solution, and balance it as in Example 5-6. Then, add to each side of the overall redox equation a number of OH^- ions equal to the number of H^+ ions. Where H^+ and OH^- appear on the same side of the equation, combine them to produce H_2O molecules. If H_2O now appears on both sides of the equation, subtract the same number of H_2O molecules from each side, leaving a remainder of H_2O on just one side. This method is illustrated in Example 5-7. For ready reference, the procedure is summarized in Table 5.6.

EXAMPLE 5-7 Balancing the Equation for a Redox Reaction in Basic Solution

Balance the equation for the reaction in which cyanide ion is oxidized to cyanate ion by permanganate ion in a basic solution, and the permanganate is itself reduced to $MnO_2(s)$.

$$MnO_4^-(aq) + CN^-(aq) \longrightarrow MnO_2(s) + OCN^-(aq) \tag{5.24}$$

Analyze

The reaction occurs in basic solution. We can balance it by using the method described in Table 5.6 on the next page. The half-reactions and the overall reaction are initially treated as though they were occurring in an acidic solution and, finally, the overall equation is adjusted to a basic solution.

Solve

Step 1. *Write half-equations for the oxidation and reduction half-reactions, and balance them for Mn, C, and N atoms.*

$$\begin{aligned} MnO_4^-(aq) &\longrightarrow MnO_2(s) \\ CN^-(aq) &\longrightarrow OCN^-(aq) \end{aligned}$$

Step 2. *Balance the half-equations for O and H atoms. Add H_2O and/or H^+ as required.* In the MnO_4^- half-equation, there are four O's on the left and two on the right. Adding 2 H_2O balances the O's on the right. Since there are now four H's on the right, it is necessary to add 4 H^+ on the left side to balance them. In the CN^- half-equation, there is one O on the right but none on the left, so H_2O must be added to the left side and 2 H^+ to the right.

$$\begin{aligned} MnO_4^-(aq) + 4\,H^+(aq) &\longrightarrow MnO_2(s) + 2\,H_2O(l) \\ CN^-(aq) + H_2O(l) &\longrightarrow OCN^-(aq) + 2\,H^+(aq) \end{aligned}$$

Step 3. *Balance the half-equations for electric charge by adding the appropriate numbers of electrons.*

Reduction: $MnO_4^-(aq) + 4\,H^+(aq) + 3\,e^- \longrightarrow MnO_2(s) + 2\,H_2O(l)$

Oxidation: $CN^-(aq) + H_2O(l) \longrightarrow OCN^-(aq) + 2\,H^+(aq) + 2\,e^-$

Step 4. *Combine the half-equations to obtain an overall redox equation.* Multiply the reduction half-equation by two and the oxidation half-equation by three to obtain the common multiple $6\,e^-$ in each half-equation. Make the appropriate cancellations of H^+ and H_2O.

$$\begin{aligned} 2\,MnO_4^-(aq) + 8\,H^+(aq) + \cancel{6\,e^-} &\longrightarrow 2\,MnO_2(s) + 4\,H_2O(l) \\ 3\,CN^-(aq) + 3\,H_2O(l) &\longrightarrow 3\,OCN^-(aq) + 6\,H^+(aq) + \cancel{6\,e^-} \\ \hline \textit{Overall}\text{: } 2\,MnO_4^-(aq) + 3\,CN^-(aq) + 2\,H^+(aq) &\longrightarrow \\ &\quad 2\,MnO_2(s) + 3\,OCN^-(aq) + H_2O(l) \end{aligned}$$

Step 5. *Change from an acidic to a basic medium by adding $2\,OH^-$ to both sides of the overall equation; combine $2\,H^+$ and $2\,OH^-$ to form $2\,H_2O$, and simplify.*

$$\begin{aligned} &2\,MnO_4^-(aq) + 3\,CN^-(aq) + 2\,H^+(aq) + 2\,OH^-(aq) \longrightarrow \\ &\qquad\qquad 2\,MnO_2(s) + 3\,OCN^-(aq) + H_2O(l) + 2\,OH^-(aq) \\ &2\,MnO_4^-(aq) + 3\,CN^-(aq) + 2\,H_2O(l) \longrightarrow 2\,MnO_2(s) + 3\,OCN^-(aq) + H_2O(l) + 2\,OH^-(aq) \end{aligned}$$

Subtract one H_2O molecule from each side to obtain the overall balanced redox equation for reaction (5.24).

$$2\,MnO_4^-(aq) + 3\,CN^-(aq) + H_2O(l) \longrightarrow 2\,MnO_2(s) + 3\,OCN^-(aq) + 2\,OH^-(aq)$$

Step 6. *Verify.* Check the final overall equation to ensure that it is balanced both for number of atoms and for electric charge. For example, show that in the balanced equation from step 5, the net charge on each side of the equation is −5.

Assess

We can use the rules for assigning oxidation states (given in Table 3.2) to deduce that manganese is reduced from +7 in MnO_4^- to +4 in MnO_2. We conclude that the other substance, CN^-, is oxidized. (The rules do not allow us to assign oxidation states to C and N in CN^- or CNO^-.) Even though we cannot identify the oxidation states of C or N, we could still balance the equation for the reaction. That is one advantage of the methods we presented in Tables 5-5 and 5-6. In Chapter 10, we will discuss another method for assigning oxidation states and learn how to determine the oxidation states of C and N in such species as CN^- or CNO^-.

(continued)

PRACTICE EXAMPLE A: Balance the equation for this reaction in basic solution.

$$S(s) + OCl^-(aq) \longrightarrow SO_3^{2-}(aq) + Cl^-(aq)$$

PRACTICE EXAMPLE B: Balance the equation for this reaction in basic solution.

$$MnO_4^-(aq) + SO_3^{2-}(aq) \longrightarrow MnO_2(s) + SO_4^{2-}(aq)$$

▶ As an alternative method for half-equations in basic solutions, add *two* OH^- for every O required to the O-deficient side, and add *one* H_2O to the other side (the net effect is adding one O to the O-deficient side). Then add *one* H_2O for every H required to the H-deficient side, and add *one* OH^- to the other side (the net effect is adding one H to the H-deficient side).

TABLE 5.6 Balancing Equations for Redox Reactions in Basic Aqueous Solutions by the Half-Equation Method: A Summary

- Balance the equation as if the reaction were occurring in acidic medium by using the method for acidic aqueous solutions summarized in Table 5-5.
- Add a number of OH^- ions equal to the number of H^+ ions to both sides of the overall equation.
- On the side of the overall equation containing both H^+ and OH^- ions, combine them to form H_2O molecules. If H_2O molecules now appear on both sides of the overall equation, cancel the same number from each side, leaving a remainder of H_2O on just one side.
- Check that both numbers of atoms and charges balance.

Disproportionation Reactions

In some oxidation–reduction reactions, called **disproportionation reactions**, the same substance is both oxidized and reduced. An example is the decompostion of hydrogen peroxide, H_2O_2, into H_2O and O_2:

$$2\,H_2O_2(aq) \longrightarrow 2\,H_2O(l) + O_2(g) \qquad \textbf{(5.25)}$$

In reaction (5.25), the oxidation state of oxygen changes from -1 in H_2O_2 to -2 in H_2O (a reduction) and to 0 in $O_2(g)$ (an oxidation). H_2O_2 is both oxidized and reduced. Reaction (5.25) produces $O_2(g)$, which bubbles out of the solution. (See Figure 5-14.)

Another example is the disproportionation of $S_2O_3^{2-}$ in acid solution:

$$S_2O_3^{2-}(aq) + 2\,H^+(aq) \longrightarrow S(s) + SO_2(g) + H_2O(l) \qquad \textbf{(5.26)}$$

The oxidation states of S are +2 in $S_2O_3^{2-}$, 0 in S, and +4 in SO_2. Thus, $S_2O_3^{2-}$ is simultaneously oxidized and reduced. Solutions of sodium thiosulfate ($Na_2S_2O_3$) are often used in the laboratory in redox reactions, and stock solutions of $Na_2S_2O_3$ sometimes develop small deposits of sulfur, a pale yellow solid, over time.

The same substance appears on the left side in each half-equation for a disproportionation reaction. The balanced half-equations and overall equation for reaction (5.26) are given below.

$$\begin{array}{ll}
\textit{Oxidation:} & S_2O_3^{2-}(aq) + H_2O(l) \longrightarrow 2\,SO_2(g) + 2\,H^+(aq) + \cancel{4e^-} \\
\textit{Reduction:} & S_2O_3^{2-}(aq) + 6\,H^+(aq) + \cancel{4e^-} \longrightarrow 2\,S(s) + 3\,H_2O(l) \\
\hline
 & 2\,S_2O_3^{2-}(aq) + 4\,H^+(aq) \longrightarrow 2\,S(s) + 2\,SO_2(g) + 2\,H_2O(l) \\
\textit{Overall:} & S_2O_3^{2-}(aq) + 2\,H^+(aq) \longrightarrow S(s) + SO_2(g) + H_2O(l)
\end{array}$$

▲ FIGURE 5-14
Antiseptic action of hydrogen peroxide solution
Dilute aqueous solutions of hydrogen peroxide (usually 3% hydrogen peroxide by mass) were once commonly used to clean minor cuts and scrapes. A solution of hydrogen peroxide bubbles when poured over a cut because of the production of gaseous oxygen.

5-5 CONCEPT ASSESSMENT

Is it possible for two different reactants in a redox reaction to yield a single product? Explain.

5-2 ARE YOU WONDERING...

How to balance the equation for a redox reaction that occurs in a medium other than an aqueous solution?

An example of such a reaction is the oxidation of $NH_3(g)$ to $NO(g)$, the first step in the commercial production of nitric acid.

$$NH_3(g) + O_2(g) \longrightarrow NO(g) + H_2O(g)$$

Some people prefer a method called the *oxidation-state change method (see below)* for reactions of this type, but the half-equation method works just as well. All that is needed is to treat the reaction as if it were occurring in an aqueous acidic solution; H^+ should appear as both a reactant and a product and cancel out in the overall equation, as seen below.

Oxidation: $4\{NH_3 + H_2O \longrightarrow NO + 5\,H^+ + 5\,e^-\}$

Reduction: $5\{O_2 + 4\,H^+ + 4\,e^- \longrightarrow 2\,H_2O\}$

Overall: $4\,NH_3 + 5\,O_2 \longrightarrow 4\,NO + 6\,H_2O$

Oxidation-state change method

In this method, changes in oxidation states are identified. That of nitrogen increases from -3 in NH_3 to $+2$ in NO, corresponding to a "loss" of five electrons per N atom. That of oxygen decreases from 0 in O_2 to -2 in NO and H_2O, corresponding to a "gain" of two electrons per O atom. The proportion of N to O atoms must be 2 N (loss of 10 e^-) to 5 O (gain of 10 e^-).

$$2\,NH_3 + \frac{5}{2}O_2 \longrightarrow 2\,NO + 3\,H_2O \quad \text{or} \quad 4\,NH_3 + 5\,O_2 \longrightarrow 4\,NO + 6\,H_2O$$

5-6 Oxidizing and Reducing Agents

Chemists frequently use the terms *oxidizing agent* and *reducing agent* to describe certain of the reactants in redox reactions, as in statements like "fluorine gas is a powerful oxidizing agent," or "calcium metal is a good reducing agent." Let us briefly consider the meaning of these terms.

In a redox reaction, the substance that makes it possible for some other substance to be oxidized is called the **oxidizing agent**, or **oxidant**. In doing so, the oxidizing agent is itself reduced. Similarly, the substance that causes some other substance to be reduced is called the **reducing agent**, or **reductant**. In the reaction, the reducing agent is itself oxidized. Or, stated in other ways,

An oxidizing agent (oxidant)

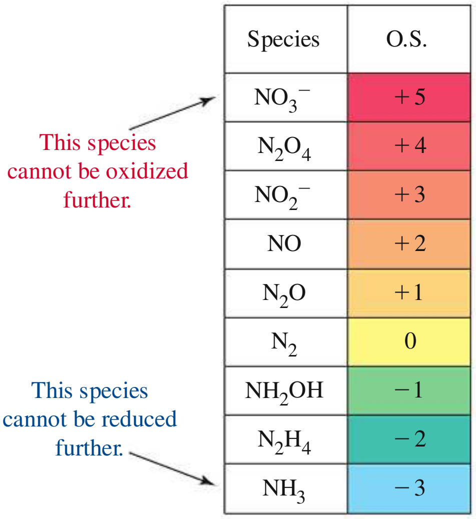
- causes another substance to be oxidized
- contains an element whose oxidation state *decreases* in a redox reaction
- *gains* electrons (electrons are found on the left side of its half-equation)
- is reduced

A reducing agent (reductant)

- causes another substance to be reduced
- contains an element whose oxidation state *increases* in a redox reaction
- *loses* electrons (electrons are found on the right side of its half-equation)
- is oxidized

In general, a substance with an element in one of its highest possible oxidation states is an oxidizing agent. If the element is in one of its lowest possible oxidation states, the substance is a reducing agent.

▶ FIGURE 5-15
Oxidation states of nitrogen: Identifying oxidizing and reducing agents
In NO_3^- and N_2O_4, nitrogen is in one of its highest possible oxidation states (O.S). These species are usually oxidizing agents in redox reactions. In N_2H_4 and NH_3, nitrogen is in one of its lowest oxidation states. These species are usually reducing agents.



Species	O.S.
NO_3^-	+5
N_2O_4	+4
NO_2^-	+3
NO	+2
N_2O	+1
N_2	0
NH_2OH	−1
N_2H_4	−2
NH_3	−3

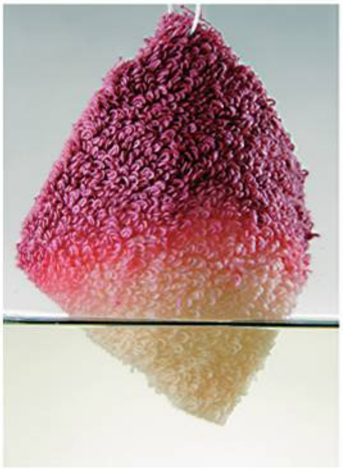
This species cannot be oxidized further.

This species cannot be reduced further.

Figure 5-15 shows the range of oxidation states of nitrogen and the species to which they correspond. The oxidation state of the nitrogen in dinitrogen tetroxide (N_2O_4) is nearly the maximum value attainable, and hence N_2O_4 is generally an oxidizing agent. Conversely, the nitrogen atom in hydrazine (N_2H_4) is in nearly the lowest oxidation state, and hence hydrazine is generally a reducing agent. When these two liquid compounds are mixed, a vigorous reaction takes place:

$$N_2O_4(l) + 2\,N_2H_4(l) \longrightarrow 3\,N_2(g) + 4\,H_2O(g)$$

In this reaction, N_2O_4 is the oxidizing agent and N_2H_4 is the reducing agent. This reaction releases so much energy that it is used in some rocket propulsion systems.



▲ FIGURE 5-16
Bleaching action of NaOCl(aq)
A red cloth becomes white when immersed in NaOCl(aq), which oxidizes the red pigment to colorless products.

Certain substances in which the oxidation state of an element is between its highest and lowest possible values may act as oxidizing agents in some instances and reducing agents in others. For example, in the reaction of hydrazine with hydrogen to produce ammonia, hydrazine acts as an oxidizing agent.

$$N_2H_4(l) + H_2(g) \longrightarrow 2\,NH_3(g)$$

Permanganate ion, MnO_4^-, is a versatile oxidizing agent that has many uses in the chemical laboratory. In the next section, we describe its use in the quantitative analysis of iron—that is, the determination of the exact (quantitative) amount of iron in an iron-containing material. Ozone, $O_3(g)$, a triatomic form of oxygen, is an oxidizing agent used in water purification, as in the oxidation of the organic compound phenol, C_6H_5OH.

$$C_6H_5OH(aq) + 14\,O_3(g) \longrightarrow 6\,CO_2(g) + 3\,H_2O(l) + 14\,O_2(g)$$

Aqueous sodium hypochlorite, NaOCl(aq), is a powerful oxidizing agent. It is the active ingredient in many liquid chlorine bleaches. The bleaching action of NaOCl(aq) is associated with the reduction of the OCl^- ion to Cl^-; the electrons required for the reduction come from colored compounds in stains. The bleaching action of NaOCl(aq) is demonstrated in Figure 5-16.

Thiosulfate ion, $S_2O_3^{2-}$, is an important reducing agent. One of its industrial uses is as an antichlor to destroy residual chlorine from the bleaching of fibers.

$$S_2O_3^{2-}(aq) + 4\,Cl_2(aq) + 5\,H_2O(l) \longrightarrow 2\,HSO_4^-(aq) + 8\,H^+(aq) + 8\,Cl^-(aq)$$

Oxidizing and reducing agents also play important roles in biological systems—in photosynthesis (using solar energy to synthesize glucose), metabolism (oxidizing glucose), and the transport of oxygen.

EXAMPLE 5-8 Identifying Oxidizing and Reducing Agents

Hydrogen peroxide, H_2O_2, is a versatile chemical. Its uses include bleaching wood pulp and fabrics and substituting for chlorine in water purification. One reason for its versatility is that it can be either an oxidizing or a reducing agent. For the following reactions, identify whether hydrogen peroxide is an oxidizing or reducing agent.

(a) $H_2O_2(aq) + 2\,Fe^{2+}(aq) + 2\,H^+(aq) \longrightarrow 2\,H_2O(l) + 2\,Fe^{3+}(aq)$

(b) $5\,H_2O_2(aq) + 2\,MnO_4^-(aq) + 6\,H^+(aq) \longrightarrow 8\,H_2O(l) + 2\,Mn^{2+}(aq) + 5\,O_2(g)$

Analyze

Before we can identify the oxidizing and reducing agents, we must first assign oxidation states, and then identify which substance is being oxidized and which substance is being reduced. The oxidizing agent causes another substance to be oxidized. The reducing agent causes another substance to be reduced.

Solve

(a) Fe^{2+} is oxidized to Fe^{3+} and because H_2O_2 makes this possible, it is an oxidizing agent. Viewed another way, we see that the oxidation state of oxygen in H_2O_2 is -1. In H_2O, it is -2. Hydrogen peroxide is reduced and thereby acts as an oxidizing agent.

(b) MnO_4^- is reduced to Mn^{2+}, and H_2O_2 makes this possible. In this situation, hydrogen peroxide is a reducing agent. Or, the oxidation state of oxygen increases from -1 in H_2O_2 to 0 in O_2. Hydrogen peroxide is oxidized and thereby acts as a reducing agent.

Assess

The versatility of H_2O_2 lies in its ability to act as an oxidizing agent and a reducing agent. When H_2O_2 acts as an oxidizing agent, it is reduced to H_2O, in an acidic solution, as was the case in part **(a)**, or to OH^- in basic solution. When it acts as a reducing agent, it is oxidized to $O_2(g)$, as was the case in part **(b)**.

PRACTICE EXAMPLE A: Is $H_2(g)$ an oxidizing or reducing agent in this reaction? Explain.

$$2\,NO_2(g) + 7\,H_2(g) \longrightarrow 2\,NH_3(g) + 4\,H_2O(g)$$

PRACTICE EXAMPLE B: Identify the oxidizing agent and the reducing agent in the reaction.

$$4\,Au(s) + 8\,CN^-(aq) + O_2(g) + 2\,H_2O(l) \longrightarrow 4[Au(CN)_2]^-(aq) + 4\,OH^-(aq)$$

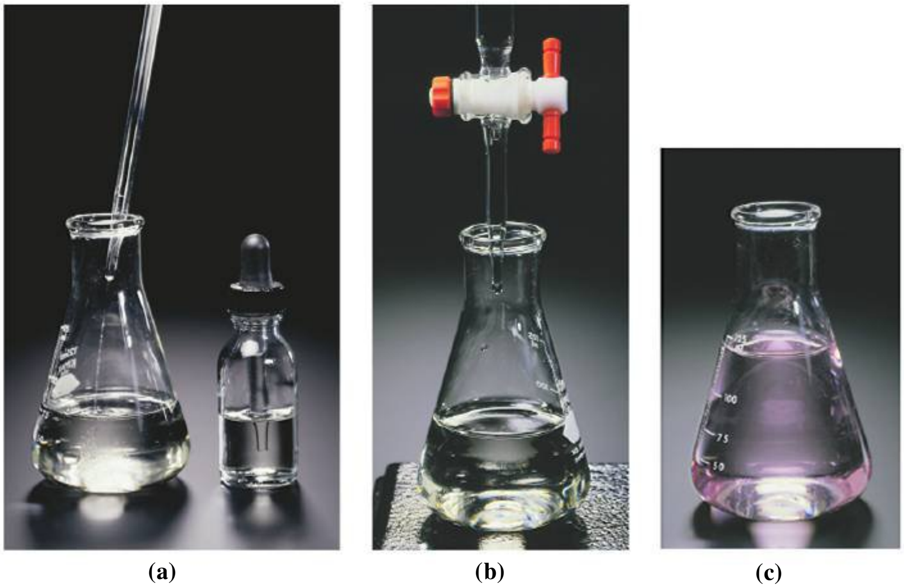
5-6 CONCEPT ASSESSMENT

A newspaper account of an accidental spill of hydrochloric acid in an area where sodium hydroxide solution was also stored spoke of the potential hazardous release of chlorine gas if the two solutions should come into contact. Was this an accurate accounting of the hazard involved? Explain.

5-7 Stoichiometry of Reactions in Aqueous Solutions: Titrations

If our objective is to obtain the maximum yield of a product at the lowest cost, we would generally choose the most expensive reactant as the limiting reactant and use excess amounts of the other reactants. This is the case in most precipitation reactions. In some instances, as in determining the concentration of a solution, we may not be interested in the products of a reaction but only in the relationship between two reactants. Then we have to carry out the reaction in such a way that neither reactant is in excess. A method that has long been used for doing this is known as *titration*. The glassware typically used in a titration is shown in Figure 5-17.

A solution of one reactant is placed in a small beaker or flask. Another reactant, also in solution and commonly referred to as titrant, is in a *buret*, a long,



▲ FIGURE 5-17
An acid–base titration—Example 5-9 illustrated
(a) A 5.00 mL sample of vinegar, a small quantity of water, and a few drops of phenolphthalein indicator are added to a flask. **(b)** 0.1000 M NaOH from a previously filled buret is slowly added. **(c)** As long as the acid is in excess, the solution in the flask remains colorless. When the acid has been neutralized, an additional drop of NaOH(aq) causes the solution to become slightly basic. The phenolphthalein indicator turns a light pink. The first lasting appearance of the pink color is taken to be the equivalence point of the titration.

▶ The key to a successful acid–base titration is in selecting the right indicator. We learn how to do this when we consider theoretical aspects of titration in Chapter 17.

graduated tube equipped with a stopcock valve. The second solution is slowly added to the first by manipulating the stopcock. **Titration** is a reaction carried out by the carefully controlled addition of one solution to another. The trick is to stop the titration at the point where both reactants have reacted completely, a condition called the **equivalence point** of the titration. Key to every titration is that at the equivalence point, the two reactants have combined in stoichiometric proportions; both have been consumed, and neither remains in excess.

In modern chemical laboratories, appropriate measuring instruments are used to signal when the equivalence point is reached. Still widely used, though, is a technique in which a very small quantity of a substance added to the reaction mixture changes color at or very near the equivalence point. Such substances are called **indicators**. Figure 5-17 illustrates the neutralization of an acid by a base by the titration technique. Calculations that use titration data are much the same as those introduced in Section 4-3, and they are also illustrated in Example 5-9.

Suppose we need a $KMnO_4(aq)$ solution of exactly known molarity, close to 0.020 M. We cannot prepare this solution by weighing out the required amount of $KMnO_4(s)$ and dissolving it in water. The solid is not pure, and its actual purity (that is, the mass percent $KMnO_4$) is *not known*. Conversely, we can obtain iron wire in essentially pure form and allow the wire to react with an acid to yield $Fe^{2+}(aq)$. $Fe^{2+}(aq)$ is oxidized to $Fe^{3+}(aq)$ by $KMnO_4(aq)$ in an acidic solution. By determining the volume of $KMnO_4(aq)$ required to oxidize a known quantity of $Fe^{2+}(aq)$, we can calculate the exact molarity of the $KMnO_4(aq)$. This procedure, which determines the exact molarity of a solution, is called **standardization of a solution**. It is illustrated in Example 5-10 and Figure 5-18.

▶ *Standardize* means determine the concentration of a solution, usually to three or four significant figures. It is not so important that the concentration be a round number (as 0.1000 vs. 0.1035 M), but rather that the concentration be accurately known.

EXAMPLE 5-9 Using Titration Data to Establish the Concentrations of Acids and Bases

Vinegar is a dilute aqueous solution of acetic acid produced by the bacterial fermentation of apple cider, wine, or other carbohydrate material. The legal minimum acetic acid content of vinegar is 4% by mass. A 5.00 mL sample of a particular vinegar is titrated with 38.08 mL of 0.1000 M NaOH. Does this sample exceed the minimum limit? (Vinegar has a density of about 1.01 g/mL.)

Analyze

Acetic acid, CH_3COOH, is a weak acid and NaOH is a strong base. The reaction between CH_3COOH and NaOH is an acid–base neutralization reaction. We start by writing a balanced chemical equation for the reaction. We must convert mL NaOH to CH_3COOH. The necessary conversions are as follows:

$$\text{mL NaOH} \longrightarrow \text{L NaOH} \longrightarrow \text{mol NaOH} \longrightarrow \text{mol CH}_3\text{COOH} \longrightarrow \text{g CH}_3\text{COOH}$$

Solve

The balanced chemical equation for the reaction is given below.

$$\text{CH}_3\text{COOH(aq)} + \text{NaOH(aq)} \longrightarrow \text{NaCH}_3\text{COO(aq)} + \text{H}_2\text{O(l)}$$

$$\begin{aligned} ?\ \text{g HC}_2\text{H}_3\text{O}_2 &= 38.08\ \text{mL} \times \frac{1\ \text{L}}{1000\ \text{mL}} \times \frac{0.1000\ \text{mol NaOH}}{1\ \text{L}} \\ &\times \frac{1\ \text{mol CH}_3\text{COOH}}{1\ \text{mol NaOH}} \times \frac{60.05\ \text{g CH}_3\text{COOH}}{1\ \text{mol CH}_3\text{COOH}} \\ &= 0.2287\ \text{g CH}_3\text{COOH} \end{aligned}$$

This mass of CH_3COOH is found in 5.00 mL of vinegar of density 1.01 g/mL. The percent mass of CH_3COOH is

$$\begin{aligned} \%\ \text{CH}_3\text{COOH} &= \frac{0.2287\ \text{g CH}_3\text{COOH}}{5.00\ \text{mL vinegar}} \times \frac{1\ \text{mL vinegar}}{1.01\ \text{g vinegar}} \times 100\% \\ &= 4.53\%\ \text{CH}_3\text{COOH} \end{aligned}$$

The vinegar sample exceeds the legal minimum limit but only slightly. There is also a standard for the maximum amount of acetic acid allowed in vinegar. A vinegar producer might use this titration technique to ensure that the vinegar stays between these limits.

Assess

Such problems as this one involve many steps or conversions. Try to break the problem into simpler ones involving fewer steps or conversions. It may also help to remember that solving a stoichiometry problem involves three steps: (1) converting to moles, (2) converting between moles, and (3) converting from moles. Use molarities and molar masses to carry out volume–mole conversions and gram–mole conversions, respectively, and stoichiometric factors to carry out mole–mole conversions. The stoichiometric factors are constructed from a balanced chemical equation.

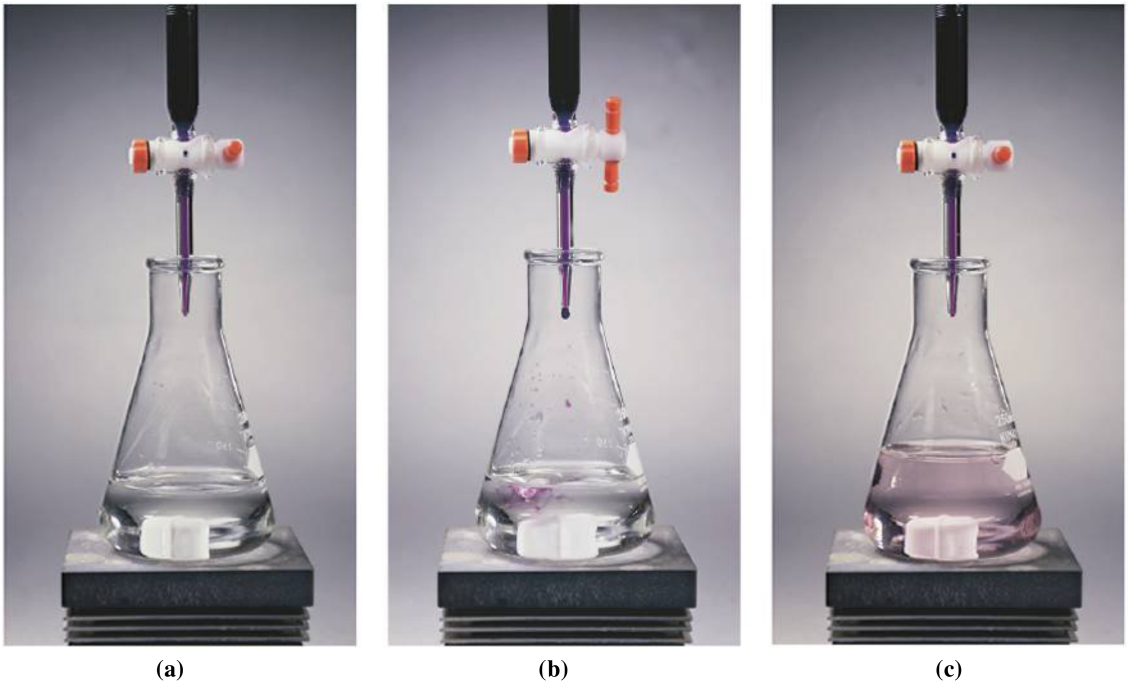
PRACTICE EXAMPLE A: A particular solution of NaOH is supposed to be approximately 0.100 M. To determine the exact molarity of the NaOH(aq), a 0.5000 g sample of $KHC_8H_4O_4$ is dissolved in water and titrated with 24.03 mL of the NaOH(aq). What is the actual molarity of the NaOH(aq)?

$$\text{HC}_8\text{H}_4\text{O}_4^{-}\text{(aq)} + \text{OH}^{-}\text{(aq)} \longrightarrow \text{C}_8\text{H}_4\text{O}_4^{2-}\text{(aq)} + \text{H}_2\text{O(l)}$$

PRACTICE EXAMPLE B: A 0.235 g sample of a solid that is 92.5% NaOH and 7.5% $Ca(OH)_2$, by mass, requires 45.6 mL of a HCl(aq) solution for its titration. What is the molarity of the HCl(aq)?

5-7 CONCEPT ASSESSMENT

A 10.00 mL sample of 0.311 M KOH is added to 31.10 mL of 0.100 M HCl. Is the resulting mixture acidic, basic, or exactly neutral? Explain.



▲ FIGURE 5-18
Standardizing a solution of an oxidizing agent through a redox titration—Example 5-10 illustrated
(a) The solution contains a known amount of Fe^{2+}, and the buret is filled with the intensely colored $KMnO_4(aq)$ to be standardized. **(b)** As it is added to the strongly acidic solution of $Fe^{2+}(aq)$, the $KMnO_4(aq)$ is immediately decolorized as a result of reaction (5.27). **(c)** When all the Fe^{2+} has been oxidized to Fe^{3+}, additional $KMnO_4(aq)$ has nothing left to oxidize and the solution turns a distinctive pink. Even a fraction of a drop of the $KMnO_4(aq)$ beyond the equivalence point is sufficient to cause this pink coloration.

EXAMPLE 5-10 Standardizing a Solution for Use in Redox Titrations

A piece of iron wire weighing 0.1568 g is converted to $Fe^{2+}(aq)$ and requires 26.24 mL of a $KMnO_4(aq)$ solution for its titration. What is the molarity of the $KMnO_4(aq)$?

$$5\,Fe^{2+}(aq) + MnO_4^-(aq) + 8\,H^+(aq) \longrightarrow 5\,Fe^{3+}(aq) + Mn^{2+}(aq) + 4\,H_2O(l) \qquad (5.27)$$

Analyze

The key to a titration calculation is that the amounts of two reactants consumed in the titration are stoichiometrically equivalent—neither reactant is in excess. We are given an amount of Fe (0.156 g) and must determine the number of moles of $KMnO_4$ in the 26.24 mL sample. The following conversions are required:

$$\text{g Fe} \longrightarrow \text{mol Fe} \longrightarrow \text{mol Fe}^{2+} \longrightarrow \text{mol MnO}_4^- \longrightarrow \text{mol KMnO}_4$$

The third conversion, from mol Fe^{2+} to mol MnO_4^-, requires a stoichiometric factor constructed from the coefficients in equation (5.27).

Solve

First, determine the amount (in moles) of $KMnO_4$ consumed in the titration.

$$\begin{aligned} ?\ \text{mol KMnO}_4 &= 0.1568\ \text{g Fe} \times \frac{1\ \text{mol Fe}}{55.847\ \text{g Fe}} \times \frac{1\ \text{mol Fe}^{2+}}{1\ \text{mol Fe}} \\ &\quad \times \frac{1\ \text{mol MnO}_4^-}{5\ \text{mol Fe}^{2+}} \times \frac{1\ \text{mol KMnO}_4}{1\ \text{mol MnO}_4^-} \\ &= 5.615 \times 10^{-4}\ \text{mol KMnO}_4 \end{aligned}$$

The volume of solution containing the 5.615×10^{-4} mol $KMnO_4$ is 26.24 mL = 0.02624 L, which means that

$$\text{concn } KMnO_4 = \frac{5.615 \times 10^{-4} \text{ mol } KMnO_4}{0.02624 \text{ L}} = 0.02140 \text{ M } KMnO_4$$

Assess

For practical applications, such as for titrations, we use solutions with molarities that are neither very large nor very small. Typically, the molarities lie in the range 0.001 M to 0.1 M. If you calculate a molarity that is significantly larger than 0.1 M, or significantly smaller than 0.001 M, then you must carefully check your calculation for possible errors.

PRACTICE EXAMPLE A: A 0.376 g sample of an iron ore is dissolved in acid, and the iron reduced to $Fe^{2+}(aq)$ and then titrated with 41.25 mL of 0.02140 M $KMnO_4$. Determine the mass percent Fe in the iron ore. [*Hint:* Use equation (5.27).]

PRACTICE EXAMPLE B: Another substance that may be used to standardize $KMnO_4(aq)$ is sodium oxalate. If 0.2482 g $Na_2C_2O_4$ is dissolved in water and titrated with 23.68 mL $KMnO_4$, what is the molarity of the $KMnO_4(aq)$?

$$MnO_4^-(aq) + C_2O_4^{2-}(aq) + H^+(aq) \longrightarrow Mn^{2+}(aq) + H_2O(l) + CO_2(g) \quad \text{(not balanced)}$$

MasteringCHEMISTRY www.masteringchemistry.com

Access to a plentiful supply of "pure water" is something most of us take for granted. Still, most of us would agree that purification of water is an important concern. The way in which water is purified depends on how it is to be used or on how it has been used. For a discussion of the removal or destruction of undesirable chemical substances from water, go to the Focus On feature for Chapter 5, entitled Water Treatment, on the MasteringChemistry site.

Summary

5-1 The Nature of Aqueous Solutions—Solutes in aqueous solution are characterized as **nonelectrolytes**, which do not produce ions, or **electrolytes**, which produce ions. **Weak electrolytes** dissociate to a limited extent, and **strong electrolytes** dissociate almost completely into ions. In addition to the molarity based on the solute as a whole, a solution's concentration can be stated in terms of the molarities of the individual solute species present—molecules and ions. Calculating ion concentrations in a strong electrolyte solution is easily done.

5-2 Precipitation Reactions—Some reactions in aqueous solution involve the combination of ions to yield a water-insoluble solid—a **precipitate**. Precipitation reactions are generally represented by **net ionic equations**, a form in which only the reacting ions and solid precipitates are shown, and **spectator ions** are deleted. Precipitation reactions usually can be predicted by using a few simple solubility guidelines (Table 5.1).

5-3 Acid–Base Reactions—According to the Arrhenius theory, a substance that ionizes to produce H^+ ions in aqueous solution is an **acid**. It is a **strong acid** (Table 5.2) if the ionization goes essentially to completion and a **weak acid** if the ionization is limited. Similarly, a **base** produces OH^- ions in aqueous solution and is either a **strong base** (Table 5.2) or a **weak base**, depending on the extent of the ionization. According to the Brønsted-Lowry theory, in an acid–base reaction, protons are transferred from the acid (the **proton donor**) to the base (the **proton acceptor**). In a typical acid–base, or **neutralization**, **reaction**, H^+ ions from the acid and OH^- ions from the base combine to form HOH (water). The other product of the reaction is an ionic compound, a **salt**. Some reactions in which gases are evolved can also be treated as acid–base reactions (Table 5.3).

5-4 Oxidation–Reduction Reactions: Some General Principles—In an **oxidation–reduction (redox) reaction** certain atoms undergo an increase in oxidation state, a process called **oxidation**. Other atoms undergo a decrease in oxidation state, or **reduction**. Another useful view of redox reactions is as the combination of separate **half-reactions** for the oxidation and the reduction.

5-5 Balancing Oxidation–Reduction Equations—An effective way to balance a redox equation is to break down the reaction into separate half-reactions, write and balance half-equations for these half-reactions, and recombine the balanced half-equations into an overall balanced equation (Table 5.5). A slight variation of this method is used for a reaction that occurs in a basic aqueous solution (Table 5.6). A redox reaction in which the same substance is both oxidized and reduced is called a **disproportionation reaction**.

5-6 Oxidizing and Reducing Agents—The **oxidizing agent** (**oxidant**) is the key reactant in an oxidation half-reaction and is *reduced* in the redox reaction. The **reducing agent** (**reductant**) is the key reactant in a reduction half-reaction and is *oxidized* in the redox reaction. Some substances act only as oxidizing agents; others, only as reducing agents. Many can act as either, depending on the reaction (Fig. 5-15).

5-7 Stoichiometry of Reactions in Aqueous Solutions: Titrations—A common laboratory technique applicable to precipitation, acid–base, and redox reactions is **titration**. The key point in a titration is the **equivalence point**, which is assessed with the aid of an **indicator**. Titration data can be used to establish a solution's molarity, called **standardization of a solution**, or to provide other information about the compositions of samples being analyzed.

Integrative Example

Sodium dithionite, $\mathrm{Na_2S_2O_4}$, is an important reducing agent. One interesting use is the reduction of chromate ion to insoluble chromium(III) hydroxide by dithionite ion, $\mathrm{S_2O_4^{2-}}$, in basic solution. Sulfite ion is another product. The chromate ion may be present in wastewater from a chromium-plating plant, for example. What mass of $\mathrm{Na_2S_2O_4}$ is consumed in a reaction with 100.0 L of wastewater having $[\mathrm{CrO_4^{2-}}] = 0.0148\ \mathrm{M}$?

◀ White solid sodium dithionite, $\mathrm{Na_2S_2O_4}$, is added to a yellow solution of potassium chromate, $\mathrm{K_2CrO_4(aq)}$ (left). A product of the reaction is gray-green chromium(III) hydroxide, $\mathrm{Cr(OH)_3(s)}$ (right).

Analyze

The phrase "reduction of chromate" tells us that the reaction between $\mathrm{CrO_4^{2-}}$ and $\mathrm{S_2O_4^{2-}}$ is a redox reaction. We must obtain a balanced chemical equation for the reaction by using the method summarized in Table 5.6, and then convert 100.0 L of wastewater into grams of $\mathrm{Na_2S_2O_4}$. The necessary conversions are as follows:

$$\text{100.0 L wastewater} \longrightarrow \text{mol}\ \mathrm{CrO_4^{2-}} \longrightarrow \text{mol}\ \mathrm{S_2O_4^{2-}} \longrightarrow \text{mol}\ \mathrm{Na_2S_2O_4} \longrightarrow \text{g}\ \mathrm{Na_2S_2O_4}$$

Solve

1. *Write an ionic expression representing the reaction.*

$$\mathrm{CrO_4^{2-}(aq) + S_2O_4^{2-}(aq) + OH^-(aq) \longrightarrow Cr(OH)_3(s) + SO_3^{2-}(aq)}$$

2. *Balance the redox equation.* Begin by writing skeleton half-equations.

$$\begin{array}{l} \mathrm{CrO_4^{2-} \longrightarrow Cr(OH)_3} \\ \mathrm{S_2O_4^{2-} \longrightarrow SO_3^{2-}} \end{array}$$

Balance the half-equations for Cr, S, O, and H atoms as if the half-reactions occur in acidic solution.

$$\begin{array}{l} \mathrm{CrO_4^{2-} + 5\,H^+ \longrightarrow Cr(OH)_3 + H_2O} \\ \mathrm{S_2O_4^{2-} + 2\,H_2O \longrightarrow 2\,SO_3^{2-} + 4\,H^+} \end{array}$$

Balance the half-equations for charge, and label them as oxidation and reduction.

$$\begin{array}{ll} \textit{Oxidation:} & \mathrm{S_2O_4^{2-} + 2\,H_2O \longrightarrow 2\,SO_3^{2-} + 4\,H^+ + 2\,e^-} \\ \textit{Reduction:} & \mathrm{CrO_4^{2-} + 5\,H^+ + 3\,e^- \longrightarrow Cr(OH)_3 + H_2O} \end{array}$$

Combine the half-equations into an overall equation.

$$\begin{array}{l} 3 \times [\mathrm{S_2O_4^{2-} + 2\,H_2O \longrightarrow 2\,SO_3^{2-} + 4\,H^+ + 2\,e^-}] \\ 2 \times [\mathrm{CrO_4^{2-} + 5\,H^+ + 3\,e^- \longrightarrow Cr(OH)_3 + H_2O}] \\ \hline \mathrm{3\,S_2O_4^{2-} + 2\,CrO_4^{2-} + 4\,H_2O \longrightarrow} \\ \qquad\qquad \mathrm{6\,SO_3^{2-} + 2\,Cr(OH)_3 + 2\,H^+} \end{array}$$

3. *Change the conditions to basic solution.* Add $2\,\mathrm{OH^-}$ to each side of the equation for acidic solution, and combine $2\,\mathrm{H^+}$ and $2\,\mathrm{OH^-}$ to form $2\,\mathrm{H_2O}$ on the right.

$$\mathrm{3\,S_2O_4^{2-} + 2\,CrO_4^{2-} + 4\,H_2O + 2\,OH^- \longrightarrow 6\,SO_3^{2-} + 2\,Cr(OH)_3 + 2\,H_2O}$$

Subtract $2\,\mathrm{H_2O}$ from each side of the equation to obtain the final balanced equation.

$$\mathrm{3\,S_2O_4^{2-}(aq) + 2\,CrO_4^{2-}(aq) + 2\,H_2O(l) + 2\,OH^-(aq) \longrightarrow 6\,SO_3^{2-}(aq) + 2\,Cr(OH)_3(s)}$$

4. *Complete the stoichiometric calculation.* The conversion pathway is
$100.0\ \text{L waste water} \longrightarrow \text{mol}\ CrO_4^{2-} \longrightarrow \text{mol}\ S_2O_4^{2-} \longrightarrow \text{mol}\ Na_2S_2O_4 \longrightarrow \text{g}\ Na_2S_2O_4$.

$$? \text{ g } Na_2S_2O_4 = 100.0\ \text{L} \times \frac{0.0148\ \text{mol}\ CrO_4^{2-}}{1\ \text{L}} \times \frac{3\ \text{mol}\ S_2O_4^{2-}}{2\ \text{mol}\ CrO_4^{2-}} \times \frac{1\ \text{mol}\ Na_2S_2O_4}{1\ \text{mol}\ S_2O_4^{2-}} \times \frac{174.1\ \text{g}\ Na_2S_2O_4}{1\ \text{mol}\ Na_2S_2O_4} = 387\ \text{g}\ Na_2S_2O_4$$

Assess

In solving this problem the major effort was to balance a redox equation for a reaction under basic conditions. This allowed us to find the molar relationship between dithionite and chromate ions. The remainder of the problem was a stoichiometry calculation for a reaction in solution, much like Example 4-11 (page 128). A quick check of the final result involves (1) ensuring that the redox equation is balanced, and (2) noting that the number of moles of CrO_4^{2-} is about 1.5 (i.e., 100×0.0148), that the number of moles of $S_2O_4^{2-}$ is about 2.25 (i.e., $1.5 \times 3/2$), and that the mass of $Na_2S_2O_4$ is somewhat more than 350 (i.e., 2.25×175).

PRACTICE EXAMPLE A: The amount of potassium chlorate, $KClO_3$, in a 0.1432 g sample was determined as follows. The sample was dissolved in 50.00 mL of 0.09101 M $Fe(NO_3)_2$ and the solution was acidified. The excess Fe^{2+} was back-titrated with 12.59 mL of 0.08362 M $Ce(NO_3)_4$ solution. What is the percentage by mass of $KClO_3$ in the sample? Chemical equations for the reactions involved are as follows:
$ClO_3^-(aq) + Fe^{2+}(aq) \rightarrow Cl^-(aq) + Fe^{3+}(aq)$ (not balanced) and $Fe^{2+}(aq) + Ce^{4+}(aq) \rightarrow Fe^{3+}(aq) + Ce^{3+}(aq)$.

PRACTICE EXAMPLE B: The amount of arsenic, As, in a 7.25 g sample was determined by converting all the arsenic in the sample to arsenous acid (H_3AsO_3), and then titrating H_3AsO_3 with 23.77 mL of 0.02144 M $KMnO_4$. What is the percentage by mass of As in the sample? The unbalanced chemical equation for the titration reaction is
$H_3AsO_3(aq) + MnO_4^-(aq) \rightarrow H_3AsO_4(aq) + Mn^{2+}(aq)$.

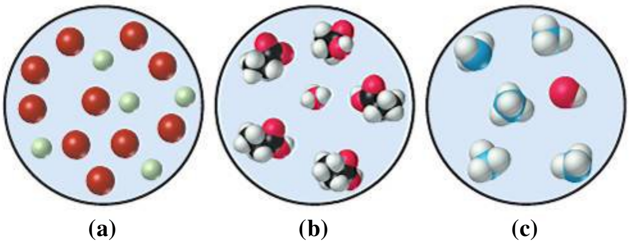
Exercises

Strong Electrolytes, Weak Electrolytes, and Nonelectrolytes

1. Using information from this chapter, indicate whether each of the following substances in aqueous solution is a nonelectrolyte, weak electrolyte, or strong electrolyte. **(a)** HC_6H_5O; **(b)** Li_2SO_4; **(c)** MgI_2; **(d)** $(CH_3CH_2)_2O$; **(e)** $Sr(OH)_2$.
2. Select the **(a)** best and **(b)** poorest electrical conductors from the following solutions, and explain the reason for your choices: 0.10 M NH_3; 0.10 M NaCl; 0.10 M CH_3COOH (acetic acid); 0.10 M CH_3CH_2OH (ethanol).
3. What response would you expect in the apparatus of Figure 5-4 if the solution tested were 1.0 M HCl? What response would you expect if the solution were both 1.0 M HCl and 1.0 M CH_3COOH?
4. $NH_3(aq)$ conducts electric current only weakly. The same is true for $CH_3COOH(aq)$. When these solutions are mixed, however, the resulting solution is a good conductor. How do you explain this?
5. Sketches **(a–c)** are molecular views of the solute in an aqueous solution. For each of the sketches, indicate whether the solute is a strong, weak, or nonelectrolyte; and which of these substances it is: sodium chloride, propionic acid, hypochlorous acid, ammonia, barium bromide, ammonium chloride, methanol.



(a) (b) (c)

6. After identifying the three substances represented by the sketches in Exercise 5, sketch molecular views of aqueous solutions of the remaining four substances listed.

Ion Concentrations

7. Determine the concentration of the ion indicated in each solution. **(a)** $[K^+]$ in 0.238 M KNO_3; **(b)** $[NO_3^-]$ in 0.167 M $Ca(NO_3)_2$; **(c)** $[Al^{3+}]$ in 0.083 M $Al_2(SO_4)_3$; **(d)** $[Na^+]$ in 0.209 M Na_3PO_4.
8. Which solution has the greatest $[SO_4^{2-}]$: **(a)** 0.075 M H_2SO_4; **(b)** 0.22 M $MgSO_4$; **(c)** 0.15 M Na_2SO_4; **(d)** 0.080 M $Al_2(SO_4)_3$; **(e)** 0.20 M $CuSO_4$?
9. A solution is prepared by dissolving 0.132 g $Ba(OH)_2 \cdot 8\,H_2O$ in 275 mL of water solution. What is $[OH^-]$ in this solution?
10. A solution is 0.126 M KCl and 0.148 M $MgCl_2$. What are $[K^+]$, $[Mg^{2+}]$, and $[Cl^-]$ in this solution?
11. Express the following data for cations in solution as molarities. **(a)** 14.2 mg Ca^{2+}/L; **(b)** 32.8 mg K^+/100 mL; **(c)** 225 μg Zn^{2+}/mL.
12. What molarity of NaF(aq) corresponds to a fluoride ion content of 0.9 mg F^-/L, the federal government's recommended limit for fluoride ion in drinking water?
13. Which of the following aqueous solutions has the highest concentration of K^+? **(a)** 0.0850 M K_2SO_4; **(b)** a solution containing 1.25 g KBr/100 mL; **(c)** a solution having 8.1 mg K^+/mL.
14. Which aqueous solution has the greatest $[H^+]$: **(a)** 0.011 M CH_3COOH; **(b)** 0.010 M HCl; **(c)** 0.010 M H_2SO_4; **(d)** 1.00 M NH_3? Explain your choice.
15. How many milligrams of MgI_2 must be added to 250.0 mL of 0.0876 M KI to produce a solution with $[I^-] = 0.1000$ M?
16. If 25.0 mL H_2O evaporates from 1.00 L of a solution containing 12.0 mg K_2SO_4/mL, what is $[K^+]$ in the solution that remains?
17. Assuming the volumes are additive, what is the $[Cl^-]$ in a solution obtained by mixing 225 mL of 0.625 M KCl and 615 mL of 0.385 M $MgCl_2$?
18. Assuming the volumes are additive, what is the $[NO_3^-]$ in a solution obtained by mixing 275 mL of 0.283 M KNO_3, 328 mL of 0.421 M $Mg(NO_3)_2$, and 784 mL of H_2O?

Predicting Precipitation Reactions

19. Complete each of the following as a net ionic equation, indicating whether a precipitate forms. If no reaction occurs, so state.
    (a) $Na^+ + Br^- + Pb^{2+} + 2\,NO_3^- \longrightarrow$
    (b) $Mg^{2+} + 2\,Cl^- + Cu^{2+} + SO_4^{2-} \longrightarrow$
    (c) $Fe^{3+} + 3\,NO_3^- + Na^+ + OH^- \longrightarrow$
20. Complete each of the following as a net ionic equation. If no reaction occurs, so state.
    (a) $Ca^{2+} + 2\,I^- + 2\,Na^+ + CO_3^{2-} \longrightarrow$
    (b) $Ba^{2+} + S^{2-} + 2\,Na^+ + SO_4^{2-} \longrightarrow$
    (c) $2\,K^+ + S^{2-} + Ca^{2+} + 2\,Cl^- \longrightarrow$
21. Predict in each case whether a reaction is likely to occur. If so, write a net ionic equation.
    (a) $HI(aq) + Zn(NO_3)_2(aq) \longrightarrow$
    (b) $CuSO_4(aq) + Na_2CO_3(aq) \longrightarrow$
    (c) $Cu(NO_3)_2(aq) + Na_3PO_4(aq) \longrightarrow$
22. Predict in each case whether a reaction is likely to occur. If so, write a net ionic equation.
    (a) $AgNO_3(aq) + CuCl_2(aq) \longrightarrow$
    (b) $Na_2S(aq) + FeCl_2(aq) \longrightarrow$
    (c) $Na_2CO_3(aq) + AgNO_3(aq) \longrightarrow$
23. What reagent solution might you use to separate the cations in the following mixtures, that is, with one ion appearing in solution and the other in a precipitate? [*Hint:* Refer to Table 5.1, and consider water also to be a reagent.]
    (a) $BaCl_2(s)$ and $MgCl_2(s)$
    (b) $MgCO_3(s)$ and $Na_2CO_3(s)$
    (c) $AgNO_3(s)$ and $Cu(NO_3)_2(s)$
24. What reagent solution might you use to separate the cations in each of the following mixtures? [*Hint:* Refer to Exercise 23.]
    (a) $PbSO_4(s)$ and $Cu(NO_3)_2(s)$
    (b) $Mg(OH)_2(s)$ and $BaSO_4(s)$
    (c) $PbCO_3(s)$ and $CaCO_3(s)$
25. You are provided with $NaOH(aq)$, $K_2SO_4(aq)$, $Mg(NO_3)_2(aq)$, $BaCl_2(aq)$, $NaCl(aq)$, $Sr(NO_3)_2(aq)$, $AgNO_3(aq)$, and $BaSO_4(s)$. Write net ionic equations to show how you would use one or more of those reagents to obtain **(a)** $SrSO_4(s)$; **(b)** $Mg(OH)_2(s)$; **(c)** KCl(aq).
26. Write net ionic equations to show how you would use one or more of the reagents in Exercise 25 to obtain **(a)** $BaSO_4(s)$; **(b)** AgCl(s); **(c)** $KNO_3(aq)$.

Acid–Base Reactions

27. Complete each of the following as a *net ionic equation*. If no reaction occurs, so state.
    (a) $Ba^{2+} + 2\,OH^- + CH_3COOH \longrightarrow$
    (b) $H^+ + Cl^- + CH_3CH_2COOH \longrightarrow$
    (c) $FeS(s) + H^+ + I^- \longrightarrow$
    (d) $K^+ + HCO_3^- + H^+ + NO_3^- \longrightarrow$
    (e) $Mg(s) + H^+ \longrightarrow$
28. Every antacid contains one or more ingredients capable of reacting with excess stomach acid (HCl). The essential neutralization products are CO_2 and/or H_2O. Write net ionic equations to represent the neutralizing action of the following popular antacids.
    (a) Alka-Seltzer (sodium bicarbonate)
    (b) Tums (calcium carbonate)
    (c) milk of magnesia (magnesium hydroxide)
    (d) Maalox (magnesium hydroxide, aluminum hydroxide)
    (e) Rolaids $[NaAl(OH)_2CO_3]$

29. In this chapter, we described an acid as a substance capable of producing H^+ and a salt as the ionic compound formed by the neutralization of an acid by a base. Write ionic equations to show that sodium hydrogen sulfate has the characteristics of both a salt and an acid (sometimes called an *acid salt*).

30. A neutralization reaction between an acid and a base is a common method of preparing useful salts. Give net ionic equations showing how the following salts could be prepared in this way: **(a)** $(NH_4)_2HPO_4$; **(b)** NH_4NO_3; and **(c)** $(NH_4)_2SO_4$.

31. Which solutions would you use to precipitate Mg^{2+} from an aqueous solution of $MgCl_2$? Explain your choice. **(a)** $KNO_3(aq)$; **(b)** $NH_3(aq)$; **(c)** $H_2SO_4(aq)$; **(d)** $HC_2H_3O_2(aq)$.

32. Determine which of the following react(s) with HCl(aq) to produce a gas, and write a net ionic equation(s) for the reaction(s). **(a)** Na_2SO_4; **(b)** $KHSO_3$; **(c)** $Zn(OH)_2$; **(d)** $CaCl_2$.

Oxidation–Reduction (Redox) Equations

33. Assign oxidation states to the elements involved in the following reactions. Indicate which are redox reactions and which are not.

(a) $MgCO_3(s) + 2\,H^+(aq) \longrightarrow Mg^{2+}(aq) + H_2O(l) + CO_2(g)$

(b) $Cl_2(aq) + 2\,Br^-(aq) \longrightarrow 2\,Cl^-(aq) + Br_2(aq)$

(c) $Ag(s) + 2\,H^+(aq) + NO_3^-(aq) \longrightarrow Ag^+(aq) + H_2O(l) + NO_2(g)$

(d) $2\,Ag^+(aq) + CrO_4^{2-}(aq) \longrightarrow Ag_2CrO_4(s)$

34. Explain why these reactions cannot occur as written.

(a) $Fe^{3+}(aq) + MnO_4^-(aq) + H^+(aq) \longrightarrow Mn^{2+}(aq) + Fe^{2+}(aq) + H_2O(l)$

(b) $H_2O_2(aq) + Cl_2(aq) \longrightarrow ClO^-(aq) + O_2(g) + H^+(aq)$

35. Complete and balance these half-equations.

(a) $SO_3^{2-} \longrightarrow S_2O_3^{2-}$ (acidic solution)

(b) $HNO_3 \longrightarrow N_2O(g)$ (acidic solution)

(c) $Al(s) \longrightarrow Al(OH)_4^-$ (basic solution)

Indicate whether oxidation or reduction is involved.

36. Complete and balance these half-equations.

(a) $C_2O_4^{2-} \longrightarrow CO_2$ (acidic solution)

(b) $Cr_2O_7^{2-} \longrightarrow Cr^{3+}$ (acidic solution)

(c) $MnO_4^- \longrightarrow MnO_2$ (basic solution)

Indicate whether oxidation or reduction is involved.

37. Balance these equations for redox reactions occurring in acidic solution.

(a) $MnO_4^- + I^- \longrightarrow Mn^{2+} + I_2(s)$

(b) $BrO_3^- + N_2H_4 \longrightarrow Br^- + N_2$

(c) $VO_4^{3-} + Fe^{2+} \longrightarrow VO^{2+} + Fe^{3+}$

(d) $UO^{2+} + NO_3^- \longrightarrow UO_2^{2+} + NO(g)$

38. Balance these equations for redox reactions occurring in acidic solution.

(a) $P_4(s) + NO_3^- \longrightarrow H_2PO_4^- + NO(g)$

(b) $S_2O_3^{2-} + MnO_4^- \longrightarrow SO_4^{2-} + Mn^{2+}$

(c) $HS^- + HSO_3^- \longrightarrow S_2O_3^{2-}$

(d) $Fe^{3+} + NH_3OH^+ \longrightarrow Fe^{2+} + N_2O(g)$

39. Balance these equations for redox reactions in basic solution.

(a) $MnO_2(s) + ClO_3^- \longrightarrow MnO_4^- + Cl^-$

(b) $Fe(OH)_3(s) + OCl^- \longrightarrow FeO_4^{2-} + Cl^-$

(c) $ClO_2 \longrightarrow ClO_3^- + Cl^-$

(d) $Ag(s) + CrO_4^{2-} \rightarrow Ag^+ + Cr(OH)_3(s)$

40. Balance these equations for redox reactions occurring in basic solution.

(a) $CrO_4^{2-} + S_2O_4^{2-} \longrightarrow Cr(OH)_3(s) + SO_3^{2-}$

(b) $[Fe(CN)_6]^{3-} + N_2H_4 \longrightarrow [Fe(CN)_6]^{4-} + N_2(g)$

(c) $Fe(OH)_2(s) + O_2(g) \longrightarrow Fe(OH)_3(s)$

(d) $CH_3CH_2OH + MnO_4^- \longrightarrow CH_3COO^- + MnO_2(s)$

41. Balance these equations for disproportionation reactions.

(a) $Cl_2(g) \longrightarrow Cl^- + ClO_3^-$ (basic solution)

(b) $S_2O_4^{2-} \longrightarrow S_2O_3^{2-} + HSO_3^-$ (acidic solution)

42. Balance these equations for disproportionation reactions.

(a) $MnO_4^{2-} \longrightarrow MnO_2(s) + MnO_4^-$ (basic solution)

(b) $P_4(s) \longrightarrow H_2PO_2^- + PH_3(g)$ (basic solution)

(c) $S_8(s) \longrightarrow S^{2-} + S_2O_3^{2-}$ (basic solution)

(d) $As_2S_3 + H_2O_2 \longrightarrow AsO_4^{3-} + SO_4^{2-}$

43. Write a balanced equation for these redox reactions.

(a) The oxidation of nitrite ion to nitrate ion by permanganate ion, MnO_4^-, in acidic solution (MnO_4^- ion is reduced to Mn^{2+}).

(b) The reaction of manganese(II) ion and permanganate ion in basic solution to form solid manganese dioxide.

(c) The oxidation of ethanol by dichromate ion in acidic solution, producing chromium(III) ion, acetaldehyde (CH_3CHO), and water as products.

44. Write a balanced equation for the redox reactions.

(a) The reaction of aluminum metal with hydroiodic acid.

(b) The reduction of vanadyl ion (VO^{2+}) to vanadic ion (V^{3+}) in acidic solution with zinc metal as the reducing agent.

(c) The oxidation of methanol by chlorate ion in acidic solution, producing carbon dioxide gas, water, and chlorine dioxide gas as products.

45. The following reactions do not occur in aqueous solutions. Balance their equations by the half-equation method, as suggested in Are You Wondering 5-2.

(a) $CH_4(g) + NO(g) \longrightarrow CO_2(g) + N_2(g) + H_2O(g)$

(b) $H_2S(g) + SO_2(g) \longrightarrow S_8(s) + H_2O(g)$

(c) $Cl_2O(g) + NH_3(g) \longrightarrow N_2(g) + NH_4Cl(s) + H_2O(l)$

46. The following reactions do not occur in aqueous solutions. Balance their equations by the half-equation method, as suggested in Are You Wondering 5-2.

(a) $CH_4(g) + NH_3(g) + O_2(g) \longrightarrow HCN(g) + H_2O(g)$

(b) $NO(g) + H_2(g) \longrightarrow NH_3(g) + H_2O(g)$

(c) $Fe(s) + H_2O(l) + O_2(g) \longrightarrow Fe(OH)_3(s)$

Oxidizing and Reducing Agents

47. What are the oxidizing and reducing agents in the following redox reactions?

(a) $5\,SO_3^{2-} + 2\,MnO_4^- + 6\,H^+ \longrightarrow 5\,SO_4^{2-} + 2\,Mn^{2+} + 3\,H_2O$

(b) $2\,NO_2(g) + 7\,H_2(g) \longrightarrow 2\,NH_3(g) + 4\,H_2O(g)$

(c) $2[Fe(CN)_6]^{4-} + H_2O_2 + 2\,H^+ \longrightarrow 2[Fe(CN)_6]^{3-} + 2\,H_2O$

48. Thiosulfate ion, $S_2O_3^{2-}$, is a reducing agent that can be oxidized to different products, depending on the strength of the oxidizing agent and other conditions. By adding H^+, H_2O, and/or OH^- as necessary, write redox equations to show the oxidation of $S_2O_3^{2-}$ to

(a) $S_4O_6^{2-}$ by I_2 (iodide ion is another product)

(b) HSO_4^- by Cl_2 (chloride ion is another product)

(c) SO_4^{2-} by OCl^- in basic solution (chloride ion is another product)

Neutralization and Acid–Base Titrations

49. What volume of 0.0962 M NaOH is required to exactly neutralize 10.00 mL of 0.128 M HCl?

50. The exact neutralization of 10.00 mL of 0.1012 M $H_2SO_4(aq)$ requires 23.31 mL of NaOH. What must be the molarity of the NaOH(aq)?

$$H_2SO_4(aq) + 2\,NaOH(aq) \longrightarrow Na_2SO_4(aq) + 2\,H_2O(l)$$

51. How many milliliters of 2.155 M KOH are required to titrate 25.00 mL of 0.3057 M CH_3CH_2COOH (propionic acid)?

52. How many milliliters of 0.0844 M $Ba(OH)_2$ are required to titrate 50.00 mL of 0.0526 M HNO_3?

53. An NaOH(aq) solution cannot be made up to an exact concentration simply by weighing out the required mass of NaOH, because the NaOH is not pure. Also, water vapor condenses on the solid as it is being weighed. The solution must be standardized by titration. For this purpose, a 25.00 mL sample of an NaOH(aq) solution requires 28.34 mL of 0.1085 M HCl. What is the molarity of the NaOH(aq)?

$$HCl(aq) + NaOH(aq) \longrightarrow NaCl(aq) + H_2O(l)$$

54. Household ammonia, used as a window cleaner and for other cleaning purposes, is $NH_3(aq)$. The NH_3 present in a 5.00 mL sample is neutralized by 28.72 mL of 1.021 M HCl. The net ionic equation for the neutralization is

$$NH_3(aq) + H^+(aq) \longrightarrow NH_4^+(aq)$$

What is the molarity of NH_3 in the sample?

55. We want to determine the acetylsalicylic acid content of a series of aspirin tablets by titration with NaOH(aq). Each of the tablets is expected to contain about 0.32 g of $HC_9H_7O_4$. What molarity of NaOH(aq) should we use for titration volumes of about 23 mL? (This procedure ensures good precision and allows the titration of two samples with the contents of a 50 mL buret.)

$$HC_9H_7O_4(aq) + OH^-(aq) \longrightarrow C_9H_7O_4^-(aq) + H_2O(l)$$

56. For use in titrations, we want to prepare 20 L of HCl(aq) with a concentration known to four significant figures. This is a two-step procedure beginning with the preparation of a solution of about 0.10 M HCl. A sample of this dilute HCl(aq) is titrated with a NaOH(aq) solution of known concentration.

(a) How many milliliters of concentrated HCl(aq) ($d = 1.19$ g/mL; 38% HCl, by mass) must be diluted with water to 20.0 L to prepare 0.10 M HCl?

(b) A 25.00 mL sample of the approximately 0.10 M HCl prepared in part **(a)** requires 20.93 mL of 0.1186 M NaOH for its titration. What is the molarity of the HCl(aq)?

(c) Why is a titration necessary? That is, why not prepare a standard solution of 0.1000 M HCl simply by an appropriate dilution of the concentrated HCl(aq)?

57. A 25.00 mL sample of 0.132 M HNO_3 is mixed with 10.00 mL of 0.318 M KOH. Is the resulting solution acidic, basic, or exactly neutralized?

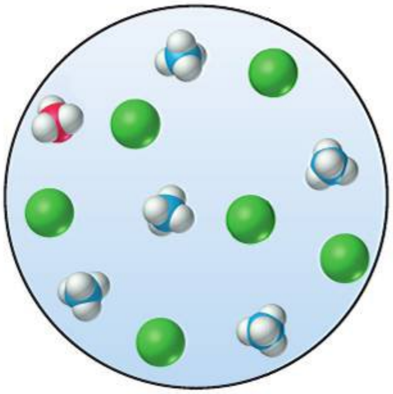
58. A 7.55 g sample of $Na_2CO_3(s)$ is added to 125 mL of a vinegar that is 0.762 M CH_3COOH. Will the resulting solution still be acidic? Explain.

59. Refer to Example 5-9. Suppose the analysis of all vinegar samples uses 5.00 mL of the vinegar and 0.1000 M NaOH for the titration. What volume of the 0.1000 M NaOH would represent the legal minimum 4.0%, by mass, acetic acid content of the vinegar? That is, calculate the volume of 0.1000 M NaOH so that if a titration requires more than this volume, the legal minimum limit is met (less than this volume, and the limit is not met).

60. The electrolyte in a lead storage battery must have a concentration between 4.8 and 5.3 M H_2SO_4 if the battery is to be most effective. A 5.00 mL sample of a battery acid requires 49.74 mL of 0.935 M NaOH for its complete reaction (neutralization). Does the concentration of the battery acid fall within the desired range? [*Hint:* Keep in mind that the H_2SO_4 produces two H^+ ions per formula unit.]

61. Which of the following points in a titration is represented by the molecular view shown in the sketch?

(a) 20% of the necessary titrant added in the titration of $NH_4Cl(aq)$ with HCl(aq)



(b) 20% of the necessary titrant added in the titration of $NH_3(aq)$ with HCl(aq)
(c) the equivalence point in the titration of $NH_3(aq)$ with HCl(aq)
(d) 120% of the necessary titrant added in the titration of $NH_3(aq)$ with HCl(aq)

62. Using the sketch in Exercise 61 as a guide, sketch the molecular view of a solution in which
(a) HCl(aq) is titrated to the equivalence point with KOH(aq)
(b) $CH_3COOH(aq)$ is titrated halfway to the equivalence point with NaOH(aq).

Stoichiometry of Oxidation–Reduction Reactions

63. A $KMnO_4(aq)$ solution is to be standardized by titration against $As_2O_3(s)$. A 0.1078 g sample of As_2O_3 requires 22.15 mL of the $KMnO_4(aq)$ for its titration. What is the molarity of the $KMnO_4(aq)$?

$$5\,As_2O_3 + 4\,MnO_4^- + 9\,H_2O + 12\,H^+ \longrightarrow 10\,H_3AsO_4 + 4\,Mn^{2+}$$

64. Refer to Example 5-6. Assume that the only reducing agent present in a particular wastewater is SO_3^{2-}. If a 25.00 mL sample of this wastewater requires 31.46 mL of 0.02237 M $KMnO_4$ for its titration, what is the molarity of SO_3^{2-} in the wastewater?

65. An iron ore sample weighing 0.9132 g is dissolved in HCl(aq), and the iron is obtained as $Fe^{2+}(aq)$. This solution is then titrated with 28.72 mL of 0.05051 M $K_2Cr_2O_7$. What is the mass percent Fe in the ore sample?

$$6\,Fe^{2+} + 14\,H^+ + Cr_2O_7^{2-} \longrightarrow 6\,Fe^{3+} + 2\,Cr^{3+} + 7\,H_2O$$

66. The concentration of $Mn^{2+}(aq)$ can be determined by titration with $MnO_4^-(aq)$ in basic solution. A 25.00 mL sample of $Mn^{2+}(aq)$ requires 37.21 mL of 0.04162 M $KMnO_4$ for its titration. What is $[Mn^{2+}]$ in the sample?

$$Mn^{2+} + MnO_4^- \longrightarrow MnO_2(s) \quad \text{(not balanced)}$$

67. The titration of 5.00 mL of a saturated solution of sodium oxalate, $Na_2C_2O_4$, at 25 °C requires 25.8 mL of 0.02140 M $KMnO_4$ in acidic solution. What mass of $Na_2C_2O_4$ in grams would be present in 1.00 L of this saturated solution?

$$C_2O_4^{2-} + MnO_4^- \longrightarrow Mn^{2+} + CO_2(g) \quad \text{(not balanced)}$$

68. Refer to the Integrative Example. In the treatment of 1.00×10^2 L of a wastewater solution that is 0.0126 M CrO_4^{2-}, how many grams of **(a)** $Cr(OH)_3(s)$ would precipitate; **(b)** $Na_2S_2O_4$ would be consumed?

Integrative and Advanced Exercises

69. Write net ionic equations for the reactions depicted in photo **(a)** sodium metal reacts with water to produce hydrogen; photo **(b)** an excess of aqueous iron(III) chloride is added to the solution in **(a)**; and photo **(c)** the precipitate from **(b)** is collected and treated with an excess of HCl(aq).

(a)

(b)

(c)

70. Following are some laboratory methods occasionally used for the preparation of small quantities of chemicals. Write a balanced equation for each.
(a) preparation of $H_2S(g)$: HCl(aq) is heated with FeS(s)
(b) preparation of $Cl_2(g)$: HCl(aq) is heated with $MnO_2(s)$; $MnCl_2(aq)$ and $H_2O(l)$ are other products
(c) preparation of N_2: Br_2 and NH_3 react in aqueous solution; NH_4Br is another product
(d) preparation of chlorous acid: an aqueous suspension of solid barium chlorite is treated with dilute $H_2SO_4(aq)$

71. When concentrated $CaCl_2(aq)$ is added to $Na_2HPO_4(aq)$, a white precipitate forms that is 38.7% Ca by mass. Write a net ionic equation representing the probable reaction that occurs.

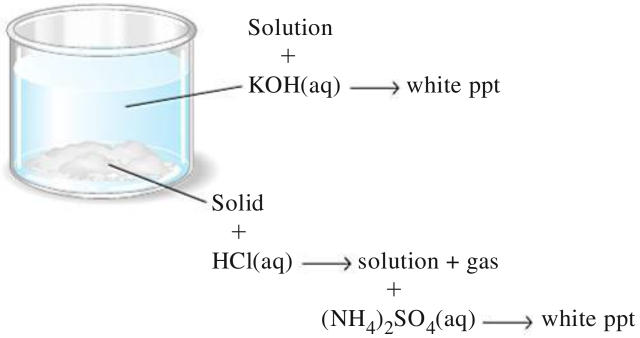
72. You have a solution that is 0.0250 M $Ba(OH)_2$ and the following pieces of equipment: 1.00, 5.00, 10.00, 25.00, and 50.00 mL pipets and 100.0, 250.0, 500.0, and 1000.0 mL volumetric flasks. Describe how you would use this equipment to produce a solution in which $[OH^-]$ is 0.0100 M.

73. Sodium hydroxide used to make standard NaOH(aq) solutions for acid–base titrations is invariably contaminated with some sodium carbonate. **(a)** Explain why, except in the most precise work, the presence of this sodium carbonate generally does not seriously affect the results obtained, for example, when NaOH(aq) is used to titrate HCl(aq). **(b)** Conversely, show that if Na_2CO_3 comprises more than 1% to 2% of the solute in NaOH(aq), the titration results are affected.

74. A 110.520 g sample of mineral water is analyzed for its magnesium content. The Mg^{2+} in the sample is first precipitated as $MgNH_4PO_4$, and this precipitate is then converted to $Mg_2P_2O_7$, which is found to weigh 0.0549 g. Express the quantity of magnesium in the sample in parts per million (that is, in grams of Mg per million grams of H_2O).

75. What volume of 0.248 M $CaCl_2$ must be added to 335 mL of 0.186 M KCl to produce a solution with a concentration of 0.250 M Cl^-? Assume that the solution volumes are additive.

76. An unknown white solid consists of two compounds, each containing a different cation. As suggested in the illustration, the unknown is partially soluble in water. The solution is treated with NaOH(aq) and yields a white precipitate. The part of the original solid that is insoluble in water dissolves in HCl(aq) with the evolution of a gas. The resulting solution is then treated with $(NH_4)_2SO_4(aq)$ and yields a white precipitate. **(a)** Is it possible that any of the cations Mg^{2+}, Cu^{2+}, Ba^{2+}, Na^+, or NH_4^+ were present in the original unknown? Explain your reasoning. **(b)** What compounds could be in the unknown mixture (that is, what anions might be present)?



77. Balance these equations for reactions in acidic solution.
(a) $IBr + BrO_3^- + H^+ \longrightarrow IO_3^- + Br^- + H_2O$
(b) $C_2H_5NO_3 + Sn \longrightarrow NH_2OH + CH_3CH_2OH + Sn^{2+}$
(c) $As_2S_3 + NO_3^- \longrightarrow H_3AsO_4 + S + NO$
(d) $H_5IO_6 + I_2 \longrightarrow IO_3^- + H^+ + H_2O$
(e) $S_2F_2 + H_2O \longrightarrow S_8 + H_2S_4O_6 + HF$

78. Balance these equations for reactions in basic solution.
(a) $Fe_2S_3 + H_2O + O_2 \longrightarrow Fe(OH)_3 + S$
(b) $O_2^- + H_2O \longrightarrow OH^- + O_2$
(c) $CrI_3 + H_2O_2 \longrightarrow CrO_4^{2-} + IO_4^-$
(d) $Ag + CN^- + O_2 + OH^- \longrightarrow [Ag(CN)_2]^- + H_2O$
(e) $B_2Cl_4 + OH^- \longrightarrow BO_2^- + Cl^- + H_2O + H_2$

79. A method of producing phosphine, PH_3, from elemental phosphorus, P_4, involves heating the P_4 with H_2O. An additional product is phosphoric acid, H_3PO_4. Write a balanced equation for this reaction.

80. Iron (Fe) is obtained from rock that is extracted from open pit mines and then crushed. The process used to obtain the pure metal from the crushed rock produces solid waste, called *tailings*, which are stored in disposal areas near the mines. The tailings pose a serious environmental risk because they contain sulfides, such as pyrite (FeS_2), which oxidize in air to produce metal ions and H^+ ions that can enter into surface water or ground water. The oxidation of FeS_2 to Fe^{3+} is described by the unbalanced chemical equation below.

$$FeS_2(s) + O_2(g) + H_2O(l) \longrightarrow Fe^{3+}(aq) + SO_4^{2-}(aq) + H^+(aq) \quad \text{(not balanced)}$$

Thus, the oxidation of pyrite produces Fe^{3+} and H^+ ions that can leach into surface or ground water. The leaching of H^+ ions causes the water to become very acidic. To prevent acidification of nearby ground or surface water, limestone ($CaCO_3$) is added to the tailings to neutralize the H^+ ions:

$$CaCO_3(s) + 2\,H^+(aq) \longrightarrow Ca^{2+}(aq) + H_2O(l) + CO_2(g)$$

(a) Balance the equation above for the reaction of FeS_2 and O_2. [*Hint:* Start with the half-equations $FeS_2(s) \rightarrow Fe^{3+}(aq) + SO_4^{2-}(aq)$ and $O_2(g) \rightarrow H_2O(l)$.]
(b) What is the minimum amount of $CaCO_3(s)$ required, per kilogram of tailings, to prevent contamination if the tailings contain 3% S by mass? Assume that all the sulfur in the tailings is in the form FeS_2.

81. A sample of battery acid is to be analyzed for its sulfuric acid content. A 1.00 mL sample weighs 1.239 g. This 1.00 mL sample is diluted to 250.0 mL, and 10.00 mL of this diluted acid requires 32.44 mL of 0.00498 M $Ba(OH)_2$ for its titration. What is the mass percent of H_2SO_4 in the battery acid? (Assume that complete ionization and neutralization of the H_2SO_4 occurs.)

82. A piece of marble (assume it is pure $CaCO_3$) reacts with 2.00 L of 2.52 M HCl. After dissolution of the marble, a 10.00 mL sample of the resulting solution is withdrawn, added to some water, and titrated with 24.87 mL of 0.9987 M NaOH. What must have been the mass of the piece of marble? Comment on the precision of this method; that is, how many significant figures are justified in the result?

83. The reaction below can be used as a laboratory method of preparing small quantities of $Cl_2(g)$. If a 62.6 g sample that is 98.5% $K_2Cr_2O_7$ by mass is allowed to react with 325 mL of HCl(aq) with a density of 1.15 g/mL and 30.1% HCl by mass, how many grams of $Cl_2(g)$ are produced?

$$Cr_2O_7^{2-} + H^+ + Cl^- \longrightarrow Cr^{3+} + H_2O + Cl_2(g) \quad \text{(not balanced)}$$

84. Refer to Example 5-10. Suppose that the $KMnO_4(aq)$ were standardized by reaction with As_2O_3 instead of iron wire. If a 0.1304 g sample that is 99.96% As_2O_3 by mass had been used in the titration, how many milliliters of the $KMnO_4(aq)$ would have been required?

$$As_2O_3 + MnO_4^- + H^+ + H_2O \longrightarrow H_3AsO_4 + Mn^{2+} \quad \text{(not balanced)}$$

85. A new method under development for water treatment uses chlorine dioxide rather than chlorine. One method of producing ClO_2 involves passing $Cl_2(g)$ into a concentrated solution of sodium chlorite. $Cl_2(g)$ and sodium chlorite are the sole reactants, and NaCl(aq) and $ClO_2(g)$ are the sole products. If the reaction has a 97% yield, what mass of ClO_2 is produced per gallon of 2.0 M $NaClO_2(aq)$ treated in this way?

86. The active component in one type of calcium dietary supplement is calcium carbonate. A 1.2450 g tablet of the supplement is added to 50.00 mL of 0.5000 M HCl and allowed to react. After completion of the reaction, the excess HCl(aq) requires 40.20 mL of 0.2184 M NaOH for its titration to the equivalence point. What is the calcium content of the tablet, expressed in milligrams of Ca^{2+}?

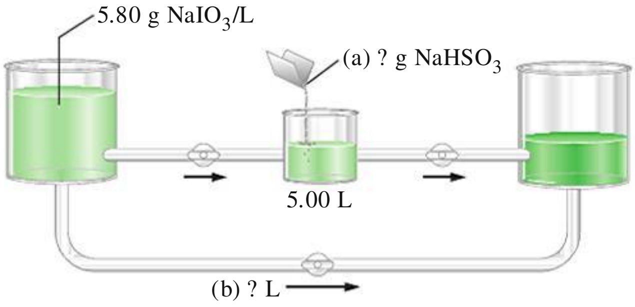
87. A 0.4324 g sample of a potassium hydroxide–lithium hydroxide mixture requires 28.28 mL of 0.3520 M HCl for its titration to the equivalence point. What is the mass percent lithium hydroxide in this mixture?

88. Chile saltpeter is a natural source of $NaNO_3$; it also contains $NaIO_3$. The $NaIO_3$ can be used as a source of iodine. Iodine is produced from sodium iodate in a two-step process occurring under acidic conditions:

$$IO_3^-(aq) + HSO_3^-(aq) \longrightarrow I^-(aq) + SO_4^{2-}(aq) \quad \text{(not balanced)}$$

$$I^-(aq) + IO_3^-(aq) \longrightarrow I_2(s) + H_2O(l) \quad \text{(not balanced)}$$

In the illustration, a 5.00 L sample of a $NaIO_3(aq)$ solution containing 5.80 g $NaIO_3$/L is treated with the stoichiometric quantity of $NaHSO_3$ (no excess of either reactant). Then, a further quantity of the initial $NaIO_3(aq)$ is added to the reaction mixture to bring about the second reaction. **(a)** How many grams of $NaHSO_3$ are required in the first step? **(b)** What additional volume of the starting solution must be added in the second step?



89. The active ingredients in a particular antacid tablet are aluminum hydroxide, $Al(OH)_3$, and magnesium hydroxide, $Mg(OH)_2$. A 5.00×10^2 mg sample of the active ingredients was dissolved in 50.0 mL of 0.500 M HCl. The resulting solution, which was still acidic, required 16.5 mL of 0.377 M NaOH for neutralization. What are the mass percentages of $Al(OH)_3$ and $Mg(OH)_2$ in the sample?

90. A compound contains only Fe and O. A 0.2729 g sample of the compound was dissolved in 50 mL of concentrated acid solution, reducing all the iron to Fe^{2+} ions. The resulting solution was diluted to 100 mL and then titrated with a 0.01621 M $KMnO_4$ solution. The unbalanced chemical equation for reaction between Fe^{2+} and MnO_4^- is given below.

$$MnO_4^-(aq) + Fe^{2+}(aq) \longrightarrow Mn^{2+}(aq) + Fe^{3+}(aq) \quad \text{(not balanced)}$$

The titration required 42.17 mL of the $KMnO_4$ solution to reach the pink endpoint. What is the empirical formula of the compound?

91. Warfarin, $C_{19}H_{16}O_4$, is the active ingredient used in some anticoagulant medications. The amount of warfarin in a particular sample was determined as follows. A 13.96 g sample was first treated with an alkaline I_2 solution to convert $C_{19}H_{16}O_4$ to CHI_3. This treatment gives one mole of CHI_3 for every mole of $C_{19}H_{16}O_4$ that was initially present in the sample. The iodine in CHI_3 is then precipitated as AgI(s) by treatment with excess $AgNO_3(aq)$:

$$CHI_3(aq) + 3\,AgNO_3(aq) + H_2O(l) \longrightarrow 3\,AgI(s) + 3\,HNO_3(aq) + CO(g)$$

If 0.1386 g solid AgI were obtained, then what is the percentage by mass of warfarin in the sample analyzed?

92. Copper refining traditionally involves "roasting" insoluble sulfide ores (CuS) with oxygen. Unfortunately, the process produces large quantities of $SO_2(g)$, which is a major contributor to pollution and acid rain. An alternative process involves treating the sulfide ore with $HNO_3(aq)$, which dissolves the CuS without generating any SO_2. The unbalanced chemical equation for the reaction is given below.

$$CuS(s) + NO_3^-(aq) \longrightarrow Cu^{2+}(aq) + NO(g) + HSO_4^-(aq) \quad \text{(not balanced)}$$

What volume of concentrated nitric acid solution is required per kilogram of CuS? Assume that the concentrated nitric acid solution is 70% HNO_3 by mass and has a density of 1.40 g/mL.

93. Phosphorus is essential for plant growth, but an excess of phosphorus can be catastrophic in aqueous ecosystems. Too much phosphorus can cause algae to grow at an explosive rate and this robs the rest of the ecosystem of oxygen. Effluent from sewage treatment plants must be treated before it can be released into lakes or streams because the effluent contains significant amounts of $H_2PO_4^-$ and HPO_4^{2-}. (Detergents are a major contributor to phosphorus levels in domestic sewage because many detergents contain Na_2HPO_4.) A simple way to remove $H_2PO_4^-$ and HPO_4^{2-} from the effluent is to treat it with lime, CaO, which produces Ca^{2+} and OH^- ions in water. The OH^- ions convert $H_2PO_4^-$ and HPO_4^{2-} ions into PO_4^{3-} ions and, finally, Ca^{2+}, OH^-, and PO_4^{3-} ions combine to form a precipitate of $Ca_5(PO_4)_3OH(s)$.

(a) Write balanced chemical equations for the four reactions described above.

[*Hint*: The reactants are CaO and H_2O; $H_2PO_4^-$ and OH^-; HPO_4^{2-} and OH^-; Ca^{2+}, PO_4^{3-}, and OH^-.]

(b) How many kilograms of lime are required to remove the phosphorus from a 1.00×10^4 L holding tank filled with contaminated water, if the water contains 10.0 mg of phosphorus per liter?

Feature Problems

94. Sodium cyclopentadienide, NaC_5H_5, is a common reducing agent in the chemical laboratory, but there is a problem in using it: NaC_5H_5 is contaminated with tetrahydrofuran (THF), C_4H_8O, a solvent used in its preparation. The THF is present as $NaC_5H_5 \cdot (THF)_x$, and it is generally necessary to know exactly how much of this $NaC_5H_5 \cdot (THF)_x$ is present. This is accomplished by allowing a small amount of the $NaC_5H_5 \cdot (THF)_x$ to react with water,

$$NaC_5H_5 \cdot (C_4H_8O)_x + H_2O \longrightarrow NaOH(aq) + C_5H_5{-}H + x\,C_4H_8O$$

followed by titration of the NaOH(aq) with a standard acid. From the sample data tabulated below, determine the value of x in the formula $NaC_5H_5 \cdot (THF)_x$.

	Trial 1	Trial 2
Mass of $NaC_5H_5 \cdot (THF)_x$	0.242 g	0.199 g
Volume of 0.1001 M HCl required to titrate NaOH(aq)	14.92 mL	11.99 mL

95. Manganese is derived from pyrolusite ore, an impure manganese dioxide. In the procedure used to analyze a pyrolusite ore for its MnO_2 content, a 0.533 g sample is treated with 1.651 g oxalic acid ($H_2C_2O_4 \cdot 2\,H_2O$) in an acidic medium. Following this reaction, the excess oxalic acid is titrated with 0.1000 M $KMnO_4$, 30.06 mL being required. What is the mass percent MnO_2 in the ore?

$$H_2C_2O_4 + MnO_2 + H^+ \longrightarrow Mn^{2+} + H_2O + CO_2 \quad \text{(not balanced)}$$

$$H_2C_2O_4 + MnO_4{}^- + H^+ \longrightarrow Mn^{2+} + H_2O + CO_2 \quad \text{(not balanced)}$$

96. The Kjeldahl method is used in agricultural chemistry to determine the percent protein in natural products. The method is based on converting all the protein nitrogen to ammonia and then determining the amount of ammonia by titration. The percent nitrogen in the sample under analysis can be calculated from the quantity of ammonia produced. Interestingly, the majority of protein molecules in living matter contain just about 16% nitrogen.

A 1.250 g sample of meat is heated with concentrated sulfuric acid and a catalyst to convert all the nitrogen in the meat to $(NH_4)_2SO_4$. Then excess NaOH(aq) is added to the mixture, which is heated to expel $NH_3(g)$. All the nitrogen from the sample is found in the $NH_3(g)$, which is then absorbed in and neutralized by 50.00 mL of dilute $H_2SO_4(aq)$. The excess $H_2SO_4(aq)$ requires 32.24 mL of 0.4498 M NaOH for its titration. A separate 25.00 mL sample of the dilute $H_2SO_4(aq)$ requires 22.24 mL of 0.4498 M NaOH for its titration. What is the percent protein in the meat?

97. Blood alcohol content (BAC) is often reported in weight–volume percent (w/v%). For example, a BAC of 0.10% corresponds to 0.10 g CH_3CH_2OH per 100 mL of blood. Estimates of BAC can be obtained from breath samples by using a number of commercially available instruments, including the Breathalyzer for which a patent was issued to R. F. Borkenstein in 1958. The chemistry behind the Breathalyzer is described by the oxidation–reduction reaction below, which occurs in acidic solution:

$$\underset{\text{ethyl alcohol}}{CH_3CH_2OH(g)} + \underset{\text{(yellow-orange)}}{Cr_2O_7{}^{2-}(aq)} \longrightarrow CH_3COOH(aq) + \underset{\text{(green)}}{Cr^{3+}(aq)} \quad \text{(not balanced)}$$

A Breathalyzer instrument contains two ampules, each of which contains 0.75 mg $K_2Cr_2O_7$ dissolved in 3 mL of 9 mol/L $H_2SO_4(aq)$. One of the ampules is used as reference. When a person exhales into the tube of the Breathalyzer, the breath is directed into one of the ampules, and ethyl alcohol in the breath converts $Cr_2O_7{}^{2-}$ into Cr^{3+}. The instrument compares the colors of the solutions in the two ampules to determine the breath alcohol content (BrAC), and then converts this into an estimate of BAC. The conversion of BrAC into BAC rests on the assumption that 2100 mL of air exhaled from the lungs contains the same amount of alcohol as 1 mL of blood. With the theory and assumptions described in this problem, calculate the molarity of $K_2Cr_2O_7$ in the ampules before and after a breath test in which a person with a BAC of 0.05% exhales 0.500 L of his breath into a Breathalyzer instrument.

98. In this problem, we describe an alternative method for balancing equations for oxidation-reduction reactions. The method is similar to the method given previously in Tables 5.5 and 5.6, but it places more emphasis on the assignment of oxidation states. (The method summarized in Tables 5.5 and 5.6 does not require you to assign oxidation states.) An emphasis on oxidation states is warranted because oxidation states are useful not only for keeping track of electrons but also for predicting chemical properties. The method is summarized in the table below.

A Method for Balancing Equations for Oxidation–Reduction Reactions That Occur in an Acidic or a Basic Aqueous Solution

1. Assign oxidation states to each element in the reaction and identify the species being oxidized and reduced.
2. Write separate, unbalanced equations for the oxidation and reduction half-reactions.
3. Balance the separate half-equations, in this order:
    - first with respect to the element being oxidized or reduced
    - then by adding electrons to one side or the other to account for the number of electrons produced (oxidation) or consumed (reduction)
4. Combine the half-reactions algebraically so that the total number of electrons cancels out.
5. Balance the net charge by either adding OH^- (for basic solutions) or H^+ (for acidic solutions).
6. Balance the O and H atoms by adding H_2O.
7. Check that the final equation is balanced with respect to each type of atom and with respect to charge.

The method offers a couple of advantages. First, the method applies to both acidic and basic environments because we balance charges by using either H^+ (for acidic environments) or OH^- (for basic environments). Second, the method is somewhat more efficient than the method we described previously because, in the method described here, we balance only once for charge and only once for hydrogen and oxygen. In the other method, we focus on the half-equations separately and must balance twice for charge and twice for hydrogen and oxygen.

Use the alternative method described above to balance the following oxidation-reduction equations.

(a) $$Cr_2O_7^{2-}(aq) + Cl^-(aq) \longrightarrow Cr^{3+}(aq) + Cl_2(g) \quad \text{(acidic solution)}$$

(b) $$C_2O_4^{2-}(aq) + MnO_4^-(aq) \longrightarrow CO_3^{2-}(aq) + MnO_2(s) \quad \text{(basic solution)}$$

Self-Assessment Exercises

99. In your own words, define or explain the terms or symbols **(a)** $\rightleftharpoons$ **(b)** [ ]; **(c)** spectator ion; **(d)** weak acid.

100. Briefly describe **(a)** half-equation method of balancing redox equations; **(b)** disproportionation reaction; **(c)** titration; **(d)** standardization of a solution.

101. Explain the important distinctions between **(a)** a strong electrolyte and strong acid; **(b)** an oxidizing agent and reducing agent; **(c)** precipitation reactions and neutralization reactions; **(d)** half-reaction and overall reaction.

102. The number of moles of hydroxide ion in 0.300 L of 0.0050 M $Ba(OH)_2$ is **(a)** 0.0015; **(b)** 0.0030; **(c)** 0.0050; **(d)** 0.010.

103. The highest $[H^+]$ will be found in an aqueous solution that is **(a)** 0.10 M HCl; **(b)** 0.10 M NH_3; **(c)** 0.15 M CH_3COOH; **(d)** 0.10 M H_2SO_4.

104. To precipitate Zn^{2+} from $Zn(NO_3)_2(aq)$, add **(a)** NH_4Cl; **(b)** $MgBr_2$; **(c)** K_2CO_3; **(d)** $(NH_4)_2SO_4$.

105. When treated with dilute HCl(aq), the solid that reacts to produce a gas is **(a)** $BaSO_3$; **(b)** ZnO; **(c)** NaBr; **(d)** Na_2SO_4.

106. What is the net ionic equation for the reaction that occurs when an aqueous solution of KI is added to an aqueous solution of $Pb(NO_3)_2$?

107. When aqueous sodium carbonate, Na_2CO_3, is treated with dilute hydrochloric acid, HCl, the products are sodium chloride, water, and carbon dioxide gas. What is the net ionic equation for this reaction?

108. Describe the synthesis of each of the following ionic compounds, starting from solutions of sodium and nitrate salts. Then write the net ionic equation for each synthesis.

(a) $Zn_3(PO_4)_2$;
(b) $Cu(OH)_2$;
(c) $NiCO_3$.

109. Consider the following redox reaction:

$$4\,NO(g) + 3\,O_2(g) + 2\,H_2O(l) \longrightarrow 4\,NO_3^-(aq) + 4\,H^+(aq)$$

(a) Which species is oxidized?
(b) Which species is reduced?
(c) Which species is the oxidizing agent?
(d) Which species is the reducing agent?
(e) Which species gains electrons?
(f) Which species loses electrons?

110. In the equation

$$?\,Fe^{2+}(aq) + O_2(g) + 4\,H^+(aq) \longrightarrow ?\,Fe^{3+}(aq) + 2\,H_2O(l)$$

the missing coefficients **(a)** are each 2; **(b)** are each 4; **(c)** can have any values as long as they are the same; **(d)** must be determined by experiment.

111. What is the simplest ratio *a*:*b* when the equation below is properly balanced?

$$a\,ClO^-(aq) + b\,I_2(aq) \xrightarrow[\text{solution}]{\text{acidic}} c\,Cl^-(aq) + d\,IO_3^-(aq)$$

(a) 2:5; **(b)** 5:2; **(c)** 1:5; **(d)** 5:1; **(e)** 2:3.

112. In the half-reaction in which NpO_2^+ is converted to Np^{4+}, the number of electrons appearing in the half-equation is **(a)** 1; **(b)** 2; **(c)** 3; **(d)** 4.

113. Classify each of the following statements as true or false.

(a) Barium chloride, $BaCl_2$, is a weak electrolyte in aqueous solution.

(b) In the reaction $H^-(aq) + H_2O(l) \rightarrow H_2(g) + OH^-(aq)$, water acts as both an acid and an oxidizing agent.

(c) A precipitate forms when aqueous sodium carbonate, $Na_2CO_3(aq)$, is treated with excess aqueous hydrochloric acid, HCl(aq).

(d) Hydrofluoric acid, HF, is a strong acid in water.

(e) Compared with a 0.010 M solution of $NaNO_3$, a 0.010 M solution of $Mg(NO_3)_2$ is a better conductor of electricity.

114. Which of the following reactions are oxidation–reduction reactions?

(a) $H_2CO_3(aq) \longrightarrow H_2O(l) + CO_2(g)$
(b) $2\,Li(s) + 2\,H_2O(l) \longrightarrow 2\,LiOH(aq) + H_2(g)$
(c) $4\,Ag(s) + PtCl_4(aq) \longrightarrow 4\,AgCl(s) + Pt(s)$
(d) $2\,HClO_4(aq) + Ca(OH)_2(aq) \longrightarrow 2\,H_2O(l) + Ca(ClO_4)_2(aq)$

115. Similar to Figure 5-4(c), but using the formulas HAc, Ac^-, and H_3O^+, give a more accurate representation of $CH_3COOH(aq)$ in which ionization is 5% complete.

116. Appendix E describes a useful study aid known as concept mapping. Using the method presented in Appendix E, construct a concept map illustrating the different concepts introduced in Sections 5-4, 5-5, and 5-6.

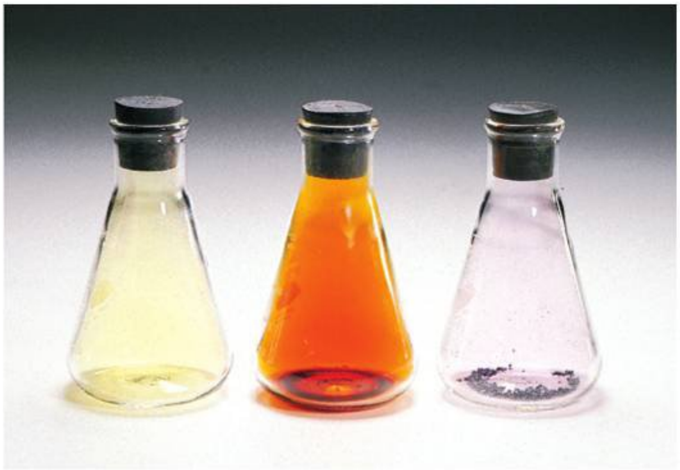
6-9 Nonideal (Real) Gases

Hot-air balloons have intrigued people from the time the simple gas laws fundamental to their operation came to be understood more than 200 years ago.

You shouldn't overinflate a bicycle tire, or discard an aerosol can in an incinerator, or search for a gas leak with an open flame. In each case there is a danger of explosion. These and many other observations concerning gases can be explained by concepts considered in this chapter. The behaviors of the bicycle tire and the aerosol can are based on relationships among pressure, temperature, volume, and amount of gas. Other examples of the behavior of gases can be seen in a balloon filled with helium or hot air rising in air and carbon dioxide gas vaporizing from a block of dry ice and sinking to the floor. An understanding of the lifting power of lighter-than-air balloons comes in large part from knowledge of gas densities and their dependence on molar mass, temperature, and pressure. Predicting how far and how fast gas molecules migrate through air requires knowing something about the phenomenon of diffusion.

For a quantitative description of the behavior of gases, we will employ some simple gas laws and a more general expression called the *ideal gas equation*. These laws will be explained by the kinetic-molecular theory of gases. The topics covered in this chapter extend the discussion of reaction stoichiometry from the previous two chapters and lay some groundwork for use



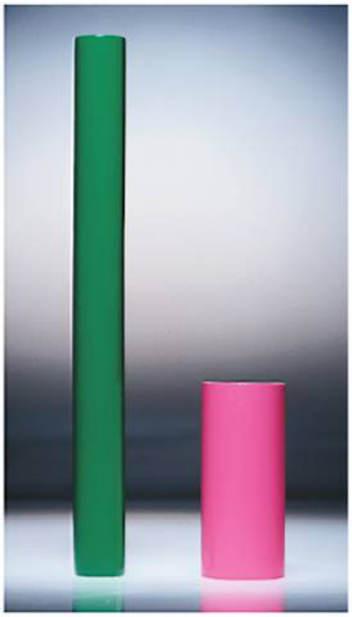
◀ FIGURE 6-1
The gaseous states of three halogens (group 17)
The greenish yellow gas is $Cl_2(g)$; the brownish red gas is $Br_2(g)$ above a small pool of liquid bromine; the violet gas is $I_2(g)$ in contact with grayish-black solid iodine. Most other common gases, such as H_2, O_2, N_2, CO, and CO_2, are colorless.

in the following chapter on thermochemistry. The relationships between gases and the other states of matter—liquids and solids—are discussed in Chapter 12.

6-1 Properties of Gases: Gas Pressure

Some characteristics of gases are familiar to everyone. Gases expand to fill their containers and assume the shapes of their containers. They diffuse into one another and mix in all proportions. We cannot see individual particles of a gas, although we can see the bulk gas if it is colored (Fig. 6-1). Some gases, such as hydrogen and methane, are combustible; whereas others, such as helium and neon, are chemically unreactive.

Four properties determine the physical behavior of a gas: the amount of the gas (in moles) and the volume, temperature, and pressure of the gas. If we know any three of these, we can usually calculate the value of the remaining one by using a mathematical equation called an *equation of state* (such as the ideal gas equation, given on page 204). To some extent we have already discussed the properties of amount, volume, and temperature, but we need to consider the idea of pressure.



▲ FIGURE 6-2
Illustrating the pressure exerted by a solid
The two cylinders have the same mass and exert the same force on the supporting surface ($F = g \times m$). The tall, thin one has a smaller area of contact, however, and exerts a greater pressure ($P = F/A$).

The Concept of Pressure

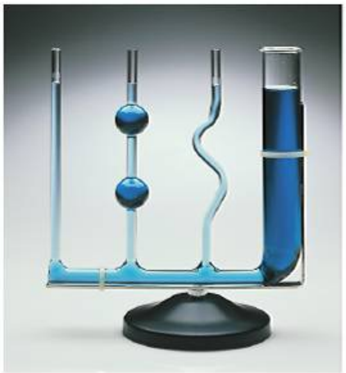
A balloon expands when it is inflated with air, but what keeps the balloon in its distended shape? A plausible hypothesis is that molecules of a gas are in constant motion, frequently colliding with one another and with the walls of their container. In their collisions, the gas molecules exert a force on the container walls. This force keeps the balloon distended. It is not easy, however, to measure the total force exerted by a gas. Instead of focusing on this total force, we consider instead the gas pressure. **Pressure** is defined as a force per unit area, that is, a force divided by the area over which the force is distributed. Figure 6-2 illustrates the idea of pressure exerted by a solid.

In SI, the unit of force is a *newton* (N), which is the force, F, required to produce an acceleration of one meter per second per second ($1\ \mathrm{m\,s^{-2}}$) in a one-kilogram mass (1 kg), that is, $1\ \mathrm{N} = 1\ \mathrm{kg\,m\,s^{-2}}$. The corresponding force per unit area—pressure—is expressed in the unit $\mathrm{N/m^2}$. A pressure of one newton per square meter is defined as one **pascal (Pa)**. Thus, a pressure in pascals is

$$P\,(\mathrm{Pa}) = \frac{F\,(\mathrm{N})}{A\,(\mathrm{m^2})} \tag{6.1}$$

◀ If you have not taken a physics course, consult Appendix B for a brief discussion of force and work.

A pascal is a rather small pressure unit, so the **kilopascal (kPa)** is more commonly used. The pascal honors Blaise Pascal (1623–1662), who studied pressure and its transmission through fluids—the basis of modern hydraulics.



▲ FIGURE 6-3
The concept of liquid pressure
All the interconnected vessels fill to the same height. As a result, the liquid pressures are the same despite the different shapes and volumes of the containers.

Liquid Pressure

Because it is difficult to measure the total force exerted by gas molecules, it is also difficult to apply equation (6.1) to gases. The pressure of a gas is usually measured indirectly, by comparing it with a liquid pressure. Figure 6-3 illustrates the concept of liquid pressure and suggests that the pressure of a liquid depends only on the height of the liquid column and the density of the liquid. To confirm this statement, consider a liquid with density d, contained in a cylinder with cross-sectional area A, filled to a height h.

Now recall that (1) weight is a force, and weight (W) and mass (m) are proportional: $W = g \times m$. (2) The mass of a liquid is the product of its volume and density: $m = V \times d$. (3) The volume of a cylinder is the product of its height and cross-sectional area: $V = h \times A$. We use these facts to derive the equation:

$$P = \frac{F}{A} = \frac{W}{A} = \frac{g \times m}{A} = \frac{g \times V \times d}{A} = \frac{g \times h \times \cancel{A} \times d}{\cancel{A}} = g \times h \times d \qquad \textbf{(6.2)}$$

Thus, because g is a constant, *liquid pressure is directly proportional to the liquid density and the height of the liquid column.*

Barometric Pressure

In 1643, Evangelista Torricelli constructed the device pictured in Figure 6-4 to measure the pressure exerted by the atmosphere. This device is called a **barometer**.

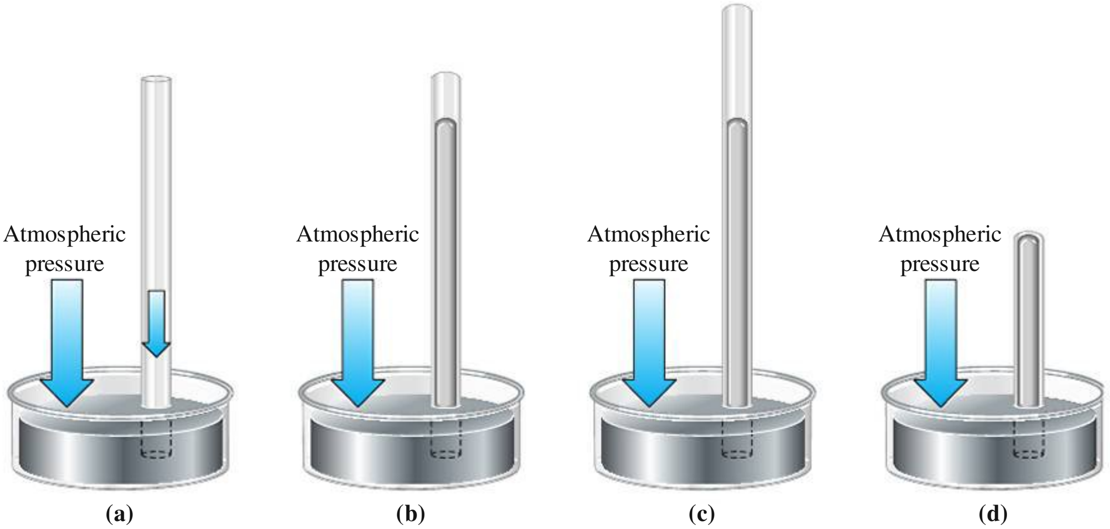
If a glass tube that is open at both ends stands upright in a container of mercury (Fig. 6-4a), the mercury levels inside and outside the tube are the same. To create the situation in Figure 6-4(b), we seal one end of a long glass tube, completely fill the tube with Hg(l), cover the open end, and invert the tube into a container of Hg(l). Then we reopen the end that is submerged in the mercury. The mercury level in the tube falls to a certain height and stays there. Something keeps the mercury at a greater height inside the tube than outside. Some tried to ascribe this phenomenon to forces within the tube, but Torricelli understood that the forces involved originated outside the tube.

In the open-end tube (Fig. 6-4a), the atmosphere exerts the same pressure on the surface of the mercury both inside and outside the tube, and the liquid levels are equal. Inside the closed-end tube (Fig. 6-4b), there is no air above the mercury (only a trace of mercury vapor). The atmosphere exerts a force on the surface of the mercury in the outside container. This force is transmitted through the liquid, holding up the mercury column within the tube. The column exerts a downward pressure that depends on its height and the density of Hg(l). When the pressure at the bottom of the mercury column is equal to the pressure of the atmosphere, the column height is maintained.

The height of mercury in a barometer provides a measure of **barometric pressure.** Barometric pressures may be expressed in a unit called **millimeter of mercury (mmHg),** defined as the pressure exerted by a column of mercury that is exactly 1 mm in height when the density of mercury is equal to 13.5951 g/cm^3(0 °C) and the acceleration due to gravity, g, is equal to 9.80655 m/s^2. Notice that this unit of pressure assumes specific values for the density of mercury and the acceleration due to gravity. This is because the density of Hg(l) depends on temperature and g depends on the specific location on Earth (recall p. 9). Typically, the pressure exerted by the atmosphere can support a column of mercury that is about 760 mm high and thus, atmospheric pressure is typically about 760 mmHg. Let's use equation (6.2) to calculate the pressure exerted by a column of mercury that is exactly 760 mm high when the density of mercury is $d = 13.5951\ g/cm^3 = 1.35951 \times 10^4\ kg/m^3$ and $g = 9.80655\ m/s^2$.

$$\begin{aligned} P &= (9.80665\ m\ s^{-2})(0.760000\ m)(1.35951\ 10^4\ k\text{-}g\ m^{-3}) \\ &= 1.01325\ 10^5\ kg\ m^{-1}\ s^{-2} \end{aligned}$$

▶ In this calculation, we have written the units of d and g in the form kg m^{-3} and m s^{-2}, respectively, rather than as kg/m^3 and m/s^2. You must become equally comfortable with using either negative exponents or a slash (/) when working with derived units. For example, the unit kg $m^{-1}\ s^{-2}$ may also be written as $kg/(m\ s^2)$.



▲ FIGURE 6-4
Measurement of atmospheric pressure with a mercury barometer
Arrows represent the pressure exerted by the atmosphere. **(a)** The liquid mercury levels are equal inside and outside the open-end tube. **(b)** A column of mercury 760 mm high is maintained in the closed-end tube, regardless of the overall height of the tube **(c)** as long as it exceeds 760 mm. **(d)** A column of mercury fills a closed-end tube that is shorter than 760 mm. In the closed-end tubes in (b) and (c), the region above the mercury column is devoid of air and contains only a trace of mercury vapor.

The unit that arises in this calculation, kg m^{-1} s^{-2}, is the SI unit for pressure and, as mentioned earlier, is called the pascal (Pa). A pressure of exactly 101,325 Pa or 101.325 kPa, has special significance because in the SI system of units, **one standard atmosphere (atm)** is defined to be exactly equal to 101,325 Pa, or 101.325 kPa. Another pressure unit that is sometimes encountered is a unit called a **torr** and denoted by the symbol **Torr**. This unit honors Torricelli and is defined as exactly 1/760 of a standard atmosphere. The following expression shows the relationships among these units.

$$1 \text{ atm} = 760 \text{ Torr} \approx 760 \text{ mmHg} \qquad \textbf{(6.3)}$$

As indicated above, the units torr and millimeters of mercury are not strictly equal. This is because 760 Torr is *exactly* equal to 101,325 Pa but 760 mmHg is only *approximately* equal to 101,325 Pa (that is, to about six or seven significant figures). The difference between a torr and a millimeter of mercury is too small to worry about, except in highly accurate work. Thus, in this text, we will use the pressure units of Torr and mmHg interchangeably.

Mercury is a relatively rare, expensive, and poisonous liquid. Why use it rather than water in a barometer? As we will see in Example 6-1, the extreme height required for a water barometer is a distinct disadvantage. Whereas atmospheric pressure can be measured with a mercury barometer less than 1 m high, a water barometer would have to be as tall as a three-storey building.

When you use a drinking straw, you reduce the air pressure above the liquid inside the straw by inhaling. Atmospheric pressure on the liquid outside the straw then pushes the liquid up the straw and into your mouth. An old-fashioned hand suction pump for pumping water (once common in rural areas) works by the same principle. The result of Example 6-1 indicates, however, that even if all the

EXAMPLE 6-1 Comparing Liquid Pressures

What is the height of a column of water that exerts the same pressure as a column of mercury 76.0 cm (760 mm) high?

Analyze

Equation (6.2) shows that, for a given liquid pressure, the column height is inversely proportional to the liquid density. The lower the liquid density, the greater the height of the liquid column. Mercury is 13.6 times as dense as water ($13.6\ \text{g/cm}^3$ versus $1.00\ \text{g/cm}^3$). If columns of water and mercury exert the same pressure, then the column of water is 13.6 times as high as the column of mercury.

Solve

Although we have already reasoned out the answer, we can arrive at the same conclusion by applying equation (6.2) twice, and then setting the two pressures equal to each other. Equation (6.2) can be used to describe the pressure of the mercury column of known height and the pressure of the water column of unknown height. Then we can set the two pressures equal to each other.

$$\text{pressure of Hg column} = g \times h_{\text{Hg}} \times d_{\text{Hg}} = g \times 76.0\ \text{cm} \times 13.6\ \text{g/cm}^3$$

$$\text{pressure of H}_2\text{O column} = g \times h_{\text{H}_2\text{O}} \times d_{\text{H}_2\text{O}} = g \times h_{\text{H}_2\text{O}} \times 1.00\ \text{g/cm}^3$$

$$\cancel{g} \times h_{\text{H}_2\text{O}} \times 1.00\ \text{g/cm}^3 = \cancel{g} \times 76.0\ \text{cm} \times 13.6\ \text{g/cm}^3$$

$$h_{\text{H}_2\text{O}} = 76.0\ \text{cm} \times \frac{13.6\ \text{g/cm}^3}{1.00\ \text{g/cm}^3} = 1.03 \times 10^3\ \text{cm} = 10.3\ \text{m}$$

Assess

We can think about equation (6.2) in another way. For a column of liquid of fixed height, the greater the density of the liquid, the greater the pressure exerted by the liquid column. A column of mercury that is 760 mm high will exert a pressure 13.6 times as great as a column of water that is 760 mm high.

PRACTICE EXAMPLE A: A barometer is filled with diethylene glycol ($d = 1.118\ \text{g/cm}^3$). The liquid height is found to be 9.25 m. What is the barometric (atmospheric) pressure expressed in millimeters of mercury?

PRACTICE EXAMPLE B: A barometer is filled with triethylene glycol. The liquid height is found to be 9.14 m when the atmospheric pressure is 757 mmHg. What is the density of triethylene glycol?

6-1 CONCEPT ASSESSMENT

Explain how the action of a water siphon is related to that of a suction pump.

$(\Delta P = g \times h \times d > 0)$
P_{gas}
h
$P_{\text{bar.}}$
Gas
$P_{\text{gas}} = P_{\text{bar.}} + \Delta P$
$(\Delta P = -g \times h \times d < 0)$

(a) The gas pressure is equal to the barometric pressure.

(b) The gas pressure is greater than the barometric pressure.

(c) The gas pressure is less than the barometric pressure.

▲ FIGURE 6-5

Measurement of gas pressure with an open-end manometer

The possible relationships between barometric pressure and a gas pressure under measurement are pictured here and described in Example 6–2. If P_{gas} and $P_{\text{bar.}}$ are expressed in mmHg, then ΔP is numerically equal to the height h expressed in millimeters.

EXAMPLE 6-2 Using a Manometer to Measure Gas Pressure

When the manometer in Figure 6-5(c) is filled with liquid mercury ($d = 13.6\ \mathrm{g/cm^3}$), the barometric pressure is 748.2 mmHg, and the difference in mercury levels is 8.6 mmHg. What is the gas pressure P_{gas}?

Analyze

We must first establish which is greater: the barometric pressure or the gas pressure. In Figure 6-5(c), the barometric pressure forces liquid mercury down the tube toward the gas sample. The barometric pressure is greater than the gas pressure. Thus, $\Delta P = P_{\text{gas}} - P_{\text{bar.}} < 0$.

Solve

The gas pressure is less than the barometric pressure. Therefore, we subtract 8.6 mmHg from the barometric pressure to obtain the gas pressure.

$$P_{\text{gas}} = P_{\text{bar.}} + \Delta P = 748.2\ \text{mmHg} - 8.6\ \text{mmHg} = 739.6\ \text{mmHg}$$

Assess

Because all pressures are expressed in millimeters of mercury, the pressure difference (ΔP) is numerically equal to the difference in mercury levels. Thus, the density of mercury does not enter into the calculation.

PRACTICE EXAMPLE A: Suppose that the mercury level in Example 6-2 is 7.8 mm higher in the arm open to the atmosphere than in the closed arm. What would be the value of P_{gas}?

PRACTICE EXAMPLE B: Suppose $P_{\text{bar.}}$ and P_{gas} are those described in Example 6-2, but the manometer is filled with liquid glycerol ($d = 1.26\ \mathrm{g/cm^3}$) instead of mercury. What would be the difference in the two levels of the liquid?

air could be removed from inside a pipe, atmospheric pressure outside the pipe could not raise water to a height of more than about 10 m. Thus, a suction pump works only for shallow wells. To pump water from a deep well, a mechanical pump is required. The mechanical pump pushes the water upward by using a force that is greater than the force of the atmosphere pushing the water down.

Manometers

Although a mercury barometer is indispensable for measuring the pressure of the atmosphere, it is rarely used alone to measure other gas pressures. The difficulty with a barometer is in placing it inside the container of gas whose pressure is to be measured. However, the pressure of the gas to be measured can be compared with barometric pressure by using a **manometer**. Figure 6-5 illustrates the principle of an open-end manometer. When the gas pressure being measured and the prevailing atmospheric (barometric) pressure are equal, the heights of the mercury columns in the two arms of the manometer are equal. A difference in height of the two arms signifies a difference between the gas pressure and barometric pressure.

Units of Pressure: A Summary

Table 6.1 lists several different units used to express pressure. The units shown in red are used frequently by chemists, even though they are not part of the SI system. The atmosphere is a useful unit because volumes of gases are often measured at the prevailing atmospheric pressure. Typically, the atmospheric pressure is close to 1 atm, or 760 Torr. The units shown in blue are those preferred in the SI system.

The units shown in black in Table 6.1 are based on the unit **bar**. One bar is 100 times as large as a kilopascal. Atmospheric pressure is typically close to 1 bar. The unit *millibar* is commonly used by meteorologists.

Although we can generally choose freely among the pressure units in Table 6.1 when doing calculations involving gases, we will encounter situations that require SI units. This is the case in Example 6-3.

TABLE 6.1 Some Common Pressure Units

Atmosphere	atm	
Millimeter of mercury	mmHg	1 atm ≃ 760 mmHg
Torr	Torr	= 760 Torr
Pascal	Pa	= 101,325 Pa
Kilopascal	kPa	= 101.325 kPa
Bar	bar	= 1.01325 bar
Millibar	mbar	= 1013.25 mbar

EXAMPLE 6-3 Using SI Units of Pressure

The 1.000 kg red cylinder in Figure 6-2 has a diameter of 4.10 cm. What pressure, expressed in Torr, does this cylinder exert on the surface beneath it?

Analyze

We must apply equation (6.2). It is best to use SI units and obtain a pressure in SI units (Pa), and then convert the pressure to the required units (Torr).

Solve

Expression (6.1) defines pressure as force divided by area.

$$P = \frac{F}{A}$$

The force exerted by the cylinder is its weight.

$$F = W = m \times g$$

The mass is 1.000 kg, and g (the acceleration due to gravity) is 9.81 m s^{-2}. The product of these two terms is the force in newtons.

$$F = m \times g = 1.000\ \text{kg} \times 9.81\ \text{m s}^{-2} = 9.81\ \text{N}$$

The force is exerted on the area of contact between the cylinder and the underlying surface. This circular area is calculated by using the radius of the cylinder—one-half the 4.10 cm diameter, expressed in meters.

$$A = \pi r^2 = 3.1416 \times \left(2.05\ \text{cm} \times \frac{1\ \text{m}}{100\ \text{cm}}\right)^2 = 1.32 \times 10^{-3}\ \text{m}^2$$

The force divided by the area (in square meters) gives the pressure in pascals.

$$P = \frac{F}{A} = \frac{9.81\ \text{N}}{1.32 \times 10^{-3}\ \text{m}^2} = 7.43 \times 10^{3}\ \text{Pa}$$

The relationship between the units Torr and pascal (Table 6.1) is used for the final conversion.

$$P = 7.43 \times 10^{3}\ \text{Pa} \times \frac{760\ \text{Torr}}{101{,}325\ \text{Pa}} = 55.7\ \text{Torr}$$

Assess

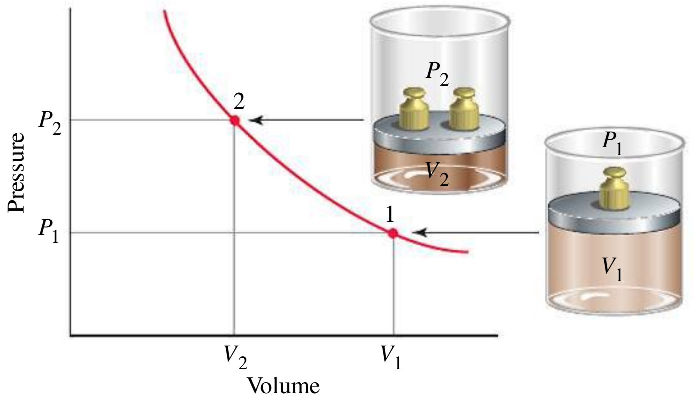
It's difficult to tell at a glance whether this is a reasonable result. To check our result, let us focus instead on a cylindrical column of mercury that is 55.7 mm high and has a diameter of 4.10 cm. This column of mercury also exerts a pressure of 55.7 mmHg = 55.7 Torr. The volume of mercury in this column is $V = \pi r^2 h = \pi \times (2.05\ \text{cm})^2 \times 5.57\ \text{cm} = 73.5\ \text{cm}^3$. The density of mercury is about 13.6 g/cm^3 (page 194) and thus, the mass of the mercury column is $73.5\ \text{cm}^3 \times 13.6\ \text{g/cm}^3 = 1.00 \times 10^3\ \text{g} = 1.00\ \text{kg}$. This is exactly the mass of the steel cylinder.

PRACTICE EXAMPLE A: The 1.000 kg green cylinder in Figure 6-2 has a diameter of 2.60 cm. What pressure, expressed in Torr, does this cylinder exert on the surface beneath it?

PRACTICE EXAMPLE B: We want to increase the pressure exerted by the 1.000 kg red cylinder in Example 6-3 to 100.0 mb by placing a weight on top of it. What must be the mass of this weight? Must the added weight have the same cross-sectional area as the cylinder? Explain.

6-2 The Simple Gas Laws

In this section, we consider relationships involving the pressure, volume, temperature, and amount of a gas. Specifically, we will see how one variable depends on another, as the remaining two are held fixed. Collectively, these relationships are referred to as the simple gas laws. You can use these laws in problem solving, but



◀ FIGURE 6-6
Relationship between gas volume and pressure—Boyle's law
When the temperature and amount of gas are held constant, gas volume is inversely proportional to the pressure: A doubling of the pressure causes the volume to decrease to one-half its original value.

you will probably prefer the equation developed in the next section—the ideal gas equation. You may find that the greatest use of the simple gas laws is in solidifying your qualitative understanding of the behavior of gases.

Boyle's Law

In 1662, working with air, Robert Boyle discovered the first of the simple gas laws, now known as **Boyle's law**.

> For a fixed amount of gas at a constant temperature, the gas volume is inversely proportional to the gas pressure. **(6.4)**

Consider the gas in Figure 6-6. It is confined in a cylinder closed off by a freely moving "weightless" piston. The pressure of the gas depends on the total weight placed on top of the piston. This weight (a force) divided by the area of the piston yields the gas pressure. If the weight on the piston is doubled, the pressure doubles and the gas volume decreases to one-half its original value. If the pressure of the gas is tripled, the volume decreases to one-third. Conversely, if the pressure is reduced by one-half, the gas volume doubles, and so on. Mathematically, the inverse relationship between gas pressure and volume is expressed as

$$P \propto \frac{1}{V} \qquad \text{or} \qquad PV = a\,(\text{a constant}) \tag{6.5}$$

When the proportionality sign ($\propto$) is replaced with an equal sign and a proportionality constant, the product of the pressure and volume of a fixed amount of gas at a given temperature is seen to be a constant (a). The value of a depends on the amount of gas and the temperature. The graph in Figure 6-6 is that of $PV = a$. It is called a hyperbola.

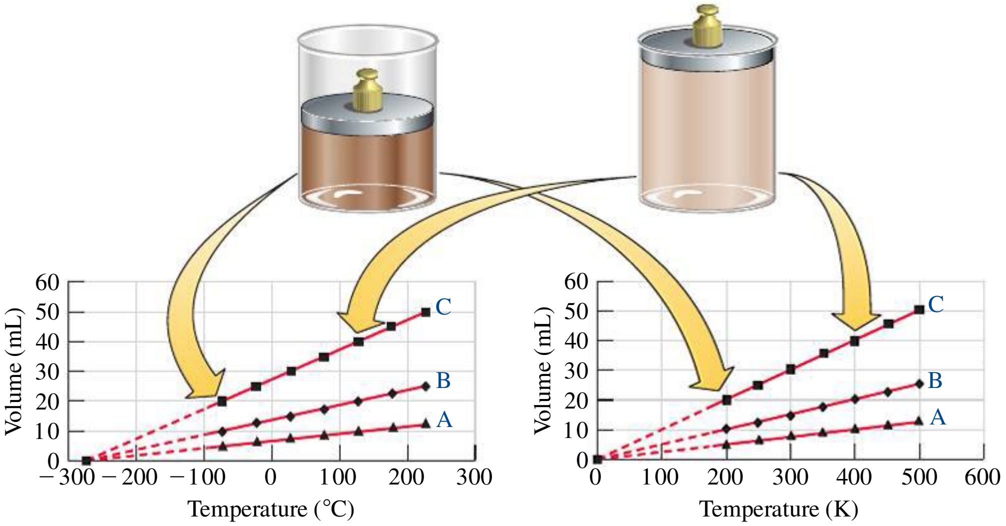
The equation $PV = a$ can be used to derive another equation that is useful for situations in which a gas undergoes a change at constant temperature. If we write equation (6.5) for the initial state (i) and for the final state (f), we get $P_i V_i = a$ and $P_f V_f = a$. Because both PV products are equal to the same value of a, we obtain the result

$$P_i V_i = P_f V_f \qquad (n \text{ constant}, T \text{ constant})$$

The equation above is often used to relate pressure and volume changes.

6-2 CONCEPT ASSESSMENT

A 50.0 L cylinder contains nitrogen gas at a pressure of 21.5 atm. The contents of the cylinder are emptied into an evacuated tank of unknown volume. If the final pressure in the tank is 1.55 atm, then what is the volume of the tank? **(a)** (21.5/1.55) × 50.0 L; **(b)** (1.55/21.5) × 50.0 L; **(c)** 21.5/(1.55 × 50) L; **(d)** 1.55/(21.5 × 50) L.



▲ FIGURE 6-7

Gas volume as a function of temperature

Volume is plotted against temperature on two different scales—Celsius and Kelvin. The volumes of three different gases (A, B, and C) are measured at 1 atm and 500 K. As the temperature is lowered, the volume decreases as predicted by Charles's law. Thus, at 250 K (−23 °C), for example, the volume of gas C has become 25 mL, one-half of the original 50 mL. Although the relationship between volume and temperature is linear for both the Celsius and Kelvin temperature scales, the volume is directly proportional only to the absolute temperature. That is, the volume must be zero at a temperature of zero. Only the Kelvin scale meets this requirement.

▶ It is probably fair to say that the absolute zero of temperature was "discovered" by noting that a plot of V (or P) vs. T for any gas extrapolates to −273 °C.

Charles's Law

The relationship between the volume of a gas and temperature was discovered by the French physicists Jacques Charles in 1787 and, independently, by Joseph Louis Gay-Lussac, who published it in 1802.

Figure 6-7 pictures a fixed amount of gas confined in a cylinder. The pressure is held constant at 1 atm while the temperature is varied. The volume of gas increases as the temperature is raised and decreases as the temperature is lowered. The relationship is linear. Figure 6-7 shows the linear dependence of volume on temperature for three gases at three different initial conditions. One point in common to the three lines is their intersection with the temperature axis. Although they differ at every other temperature, the gas volumes all reach a value of zero at the same temperature. The temperature at which the volume of a hypothetical* gas becomes zero is the absolute zero of temperature: −273.15 °C on the Celsius scale or 0 K on the **absolute**, or **Kelvin**, scale. The relationship between the Kelvin temperature, T, and the Celsius temperature, t, is shown below in equation (6.6).

▶ When converting from °C to K, apply the addition and subtraction significant figure rule: the two-significant-figure 25 °C, when added to 273.15, becomes the three-significant-figure 298 K. Similarly, 25.0 °C becomes 298.2 K (that is, 25.0 + 273.15 = 298.15, which rounds to 298.2).

$$T(\mathrm{K}) = t(^\circ\mathrm{C}) + 273.15 \tag{6.6}$$

The graph on the right hand side of Figure 6-7 shows that, from a volume of zero at 0 K, the gas volume is directly proportional to the Kelvin temperature. The statement of **Charles's law** given below in (6.7) summarizes the relationship between volume and temperature.

> The volume of a fixed amount of gas at constant pressure is directly proportional to the Kelvin (absolute) temperature. **(6.7)**

▶ Charles's ideas about the effect of temperature on the volume of a gas were probably influenced by his passion for hot-air balloons, a popular craze of the late eighteenth century.

---

*All gases condense to liquids or solids before the temperature approaches absolute zero. Also, when we speak of the volume of a gas, we mean the free volume among the gas molecules, not the volume of the molecules themselves. Thus, the gas we refer to here is *hypothetical*. It is a gas whose molecules have mass but no volume and that does not condense to a liquid or solid.

In mathematical terms, Charles's law is

$$V \propto T \qquad \text{or} \qquad V = bT \text{ (where } b \text{ is a constant)} \tag{6.8}$$

The value of the constant b depends on the amount of gas and the pressure. It does *not* depend on the identity of the gas.

From either expression (6.7) or (6.8), we see that doubling the Kelvin temperature of a gas causes its volume to double. Reducing the Kelvin temperature by one-half (say, from 300 to 150 K) causes the volume to decrease to one-half, and so on.

Equation (6.8) can be used to derive an equation that is useful for situations in which a gas undergoes a change at constant pressure. If we apply equation (6.8) twice, once for the initial state (i) and once for the final state (f), we get $(V_i/T_i) = b$ and $(V_f/T_f) = b$. Because both (V/T) quotients are equal to the same value of b, we obtain the result

$$\frac{V_i}{T_i} = \frac{V_f}{T_f} \qquad (n \text{ constant}, P \text{ constant})$$

The equation above is often used to relate volume and temperature changes.

▲ Charles experimented with the first hydrogen-filled balloons, much like the one shown here, though smaller. He also invented most of the features of modern ballooning, including the suspended basket and the valve to release gas.

6-3 CONCEPT ASSESSMENT

A balloon is inflated to a volume of 2.50 L inside a house that is kept at 24 °C. Then it is taken outside on a very cold winter day. If the temperature outside is −25 °C, what will be the volume of the balloon when it is taken outside? Assume that the quantity of air in the balloon and its pressure both remain constant.
(a) $(248/297) \times 2.50$ L; **(b)** $(297/248) \times 2.50$ L; **(c)** $248/(297 \times 2.50)$ L;
(d) $297/(248 \times 2.50)$ L.

6-4 CONCEPT ASSESSMENT

Doubling a gas temperature from 100 K to 200 K causes a gas volume to double. Would you expect a similar doubling of the gas volume when a gas is heated from 100 °C to 200 °C? Explain.

Standard Conditions of Temperature and Pressure

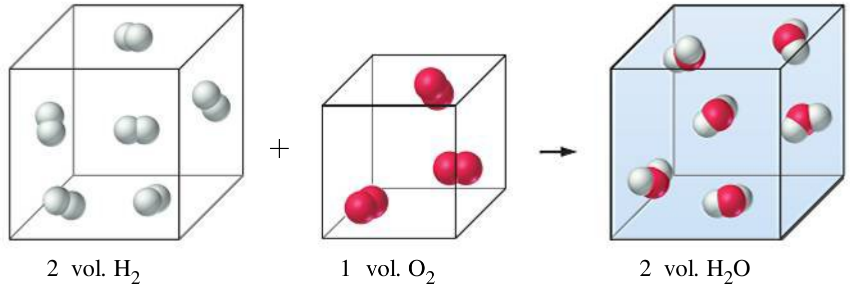
Because gas properties depend on temperature and pressure, it is useful to have a set of standard conditions of temperature and pressure that can be used for comparing different gases. The standard temperature for gases is taken to be 0 °C = 273.15 K and standard pressure, 1 bar = 100 kPa = 10^5 Pa. **Standard conditions of temperature and pressure** are usually abbreviated as **STP**. It is important to emphasize that STP was defined differently in the past, and some texts and chemists still use the old definition. The old definition, which was based on a standard pressure of 1 atm, is discouraged. In this text, we use the definition recommended by the International Union of Pure and Applied Chemistry (IUPAC):

◀ Although IUPAC has recommended that one *bar* should replace the *atmosphere* as the standard state condition for gas law and thermodynamic data, use of the atmosphere persists.

Standard Temperature and Pressure (STP): 0 °C and 1 bar = 10^5 Pa

Avogadro's Law

In 1808, Gay-Lussac reported that gases react by volumes in the ratio of small whole numbers. One proposed explanation was that equal volumes of gases at the same temperature and pressure contain equal numbers of atoms. Dalton did not agree with this proposition, however. If Gay-Lussac's proposition



▲ FIGURE 6-8
Formation of water—actual observation and Avogadro's hypothesis
In the reaction $2\,H_2(g) + 1\,O_2(g) \longrightarrow 2\,H_2O(g)$, only one-half as many O_2 molecules are required as are H_2 molecules. If equal volumes of gases contain equal numbers of molecules, this means the volume of $O_2(g)$ is one-half that of $H_2(g)$. The combining ratio by volume is 2 : 1 : 2.

were true, then the reaction of hydrogen and oxygen to form water would be $H(g) + O(g) \longrightarrow HO(g)$, with combining volumes of 1 : 1 : 1, rather than the 2 : 1 : 2 that was observed.

▶ Avogadro's hypothesis and statements derived from it apply only to gases. There is no similar relationship for liquids or solids.

In 1811, Amedeo Avogadro resolved this dilemma by proposing not only the "equal volumes–equal numbers" hypothesis, but also that molecules of a gas may break up into half–molecules when they react. Using modern terminology, we would say that O_2 molecules split into atoms, which then combine with molecules of H_2 to form H_2O molecules. In this way, the volume of oxygen needed is only one-half that of hydrogen. Avogadro's reasoning is outlined in Figure 6-8.

Avogadro's equal volumes–equal numbers hypothesis can be stated in either of two ways.

1. Equal volumes of different gases compared at the same temperature and pressure contain equal numbers of molecules.
2. Equal numbers of molecules of different gases compared at the same temperature and pressure occupy equal volumes.

"Volumi eguali di gas nelle stesse condizioni di temperatura e di pressione contengono lo stesso numero di molecole"
1856
1956
AMEDEO AVOGADRO
POSTE ITALIANE L25

▲ **Amedeo Avogadro (1776–1856)—a scientist ahead of his time**
Avogadro's hypothesis and its ramifications were not understood by his contemporaries but were effectively communicated by Stanislao Cannizzaro (1826–1910) about 50 years later.

A relationship that follows from *Avogadro's hypothesis*, often called **Avogadro's law**, is as follows.

At a fixed temperature and pressure, the volume of a gas is directly proportional to the amount of gas. **(6.9)**

If the number of moles of gas (n) is doubled, the volume doubles, and so on. A mathematical statement of this fact is

$$V \propto n \qquad \text{and} \qquad V = c \times n$$

The constant c, which is equal to V/n, is the volume per mole of gas, a quantity we call the molar volume. Molar volumes of gases vary with temperature and pressure but experiment reveals that, for given values of T and P, the molar volumes of all gases are approximately equal. (In Section 6-9, we will discuss why the molar volumes of gases are not exactly equal.) The data in Table 6.2 show that the molar volume of a gas is approximately 22.414 L at 0 °C and 1 atm and 22.711 L at STP. The following statement summarizes these observations.

$$1\text{ mol gas} = 22.414\text{ L (at 0 °C, 1 atm)} = 22.711\text{ L (at STP)} \qquad \textbf{(6.10)}$$

▶ In general, relating the amount of gas and its volume is best done with the ideal gas equation (Section 6-3).

Figure 6-9 should help you to visualize 22.414 L of a gas.

TABLE 6.2 Densities and Molar Volumes of Various Gases

Gas	Molar Mass, g mol^{-1}	Density (at STP), g L^{-1}	Molar Volume,[a] L mol^{-1}

Source: The densities are from the National Institute of Standards and Technology (NIST) *Chemistry WebBook*, available online at http://webbook.nist.gov/chemistry/.

[a] The molar volume is equal to the molar mass divided by the density. The molar volume at 0 °C and 1 atm is obtained by dividing the molar volume at STP by 1.01325.

6-5 CONCEPT ASSESSMENT

Without doing an actual calculation, determine which of the following expressions equals the final volume of gas if 20.0 g O_2 is added to 40.0 g O_2 at 0 °C and 1 atm, the temperature is changed to 30 °C, and the pressure to 825 Torr.

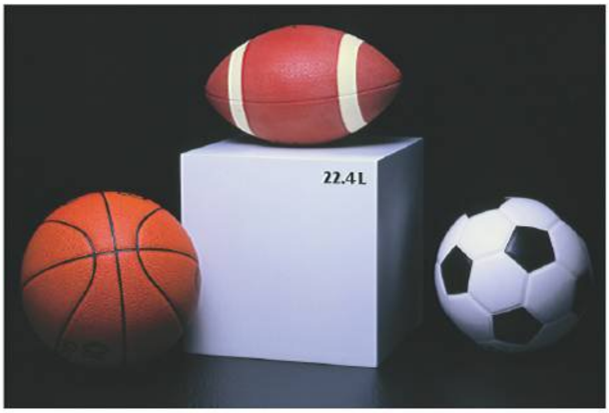
(a) $\left(\frac{40.0}{20.0} \times \frac{1}{32.00} \times 22.4 \times \frac{760}{825} \times \frac{303}{273}\right)$ L

(b) $\left(\frac{20.0}{40.0} \times \frac{1}{32.00} \times 22.4 \times \frac{825}{760} \times \frac{273}{303}\right)$ L

(c) $\left(60.0 \times \frac{1}{32.00} \times 22.4 \times \frac{825}{760} \times \frac{303}{273}\right)$ L

(d) $\left(\frac{3}{2} \times 40.0 \times \frac{1}{32.00} \times 22.4 \times \frac{760}{825} \times \frac{303}{273}\right)$ L

(e) $\left(\frac{2}{3} \times 60.0 \times \frac{1}{32.00} \times 22.4 \times \frac{760}{825} \times \frac{303}{273}\right)$ L



◀ FIGURE 6-9

Molar volume of a gas visualized

The wooden cube is 28.2 cm on edge and has approximately the same volume as one mole of gas at 1 atm and 0 °C: 22.414 L. By contrast, the volume of the basketball is 7.5 L; the soccer ball, 6.0 L; and the football, 4.4 L.

▶ The ideal gas equation will probably not be supplied on exams and should be memorized. Values of R given here, however, will be available. There is really only one R but like many properties and constants, its value can be expressed in a variety of units.

6-3 Combining the Gas Laws: The Ideal Gas Equation and the General Gas Equation

Each of the three simple gas laws describes the effect that changes in one variable have on the gas volume when the other two variables are held constant.

1. Boyle's law describes the effect of pressure, $V \propto 1/P$.
2. Charles's law describes the effect of temperature, $V \propto T$.
3. Avogadro's law describes the effect of the amount of gas, $V \propto n$.

These three laws can be combined into a single equation—the **ideal gas equation**—that includes all four gas variables: volume, pressure, temperature, and amount of gas.

The Ideal Gas Equation

In accord with the three simple gas laws, the volume of a gas is *directly* proportional to the amount of gas, *directly* proportional to the Kelvin temperature, and *inversely* proportional to pressure. That is,

$$V \propto \frac{nT}{P} \qquad \text{and} \qquad V = \frac{RnT}{P}$$

$$PV = nRT \tag{6.11}$$

A gas whose behavior conforms to the ideal gas equation is called an **ideal**, or **perfect, gas**. Before we can apply equation (6.11), we need a value for the constant R, called the **gas constant**. One way to obtain this is to substitute into equation (6.11) the molar volume of an ideal gas at 0 °C and 1 atm. However, the value of R will then depend on which units are used to express pressure and volume. With a molar volume of 22.4140 L and pressure in atmospheres,

$$R = \frac{PV}{nT} = \frac{1\text{ atm} \times 22.4140\text{ L}}{1\text{ mol} \times 273.15\text{ K}} = 0.082057\text{ atm L mol}^{-1}\text{ K}^{-1}$$

Using the SI units of m^3 for volume and Pa for pressure gives

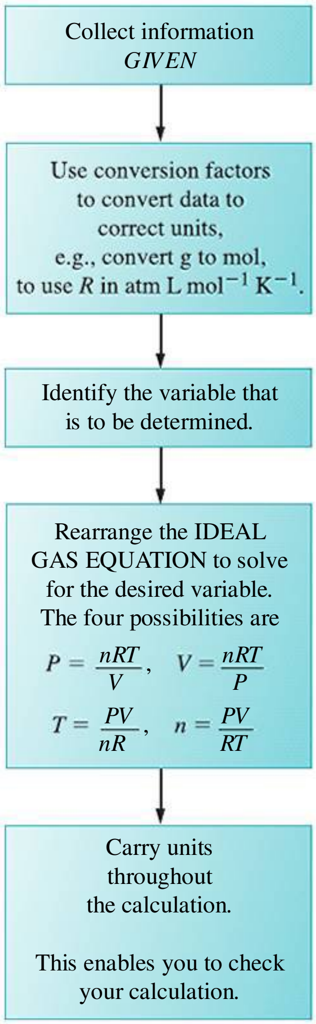
$$R = \frac{PV}{nT} = \frac{101{,}325\text{ Pa} \times 2.24140 \times 10^{-2}\text{ m}^3}{1\text{ mol} \times 273.15\text{ K}} = 8.3145\text{ Pa m}^3\text{ mol}^{-1}\text{ K}^{-1}$$

The units $\text{Pa m}^3\text{ mol}^{-1}\text{ K}^{-1}$ also have another significance. The pascal has units $\text{kg m}^{-1}\text{ s}^{-2}$, so the units $\text{m}^3\text{ Pa}$ become $\text{kg m}^2\text{ s}^{-2}$, which is the SI unit of energy—the joule. Thus R also has the value

$$R = 8.3145\text{ J mol}^{-1}\text{ K}^{-1}$$

We will use this value of R when we consider the energy involved in gas expansion and compression.

Common values of the gas constant are listed in Table 6.3, and you will have a chance to use all of them in the Practice Examples and end-of-chapter exercises in this chapter. A general strategy for applying the ideal gas equation is illustrated in the diagram in the margin.



Collect information
GIVEN
Use conversion factors to convert data to correct units, e.g., convert g to mol, to use R in atm L mol⁻¹ K⁻¹.
Identify the variable that is to be determined.
Rearrange the IDEAL GAS EQUATION to solve for the desired variable. The four possibilities are
P = nRT/V, V = nRT/P
T = PV/nR, n = PV/RT
Carry units throughout the calculation.
This enables you to check your calculation.

▲ **Applying the ideal gas equation**

TABLE 6.3 Five Common Values of R

$0.082057\text{ atm L mol}^{-1}\text{ K}^{-1}$
$0.083145\text{ bar L K}^{-1}\text{ mol}^{-1}$
$8.3145\text{ kPa L K}^{-1}\text{ mol}^{-1}$
$8.3145\text{ Pa m}^3\text{ mol}^{-1}\text{ K}^{-1}$
$8.3145\text{ J mol}^{-1}\text{ K}^{-1}$

The General Gas Equation

In Examples 6-4 and 6-5, the ideal gas equation is applied to a single set of conditions (P, V, n, and T). Sometimes a gas is described under two different

EXAMPLE 6-4 Calculating a Gas Volume with the Ideal Gas Equation

What is the volume occupied by 13.7 g $Cl_2(g)$ at 45 °C and 745 mmHg?

Analyze

This is a relatively straightforward application of the ideal gas equation. We are given an amount of gas (in grams), a pressure (in mmHg), and a temperature (in °C). Before using the ideal gas equation, we must express the amount in moles, the pressure in atmospheres, and the temperature in Kelvin. Include units throughout the calculation to ensure that the final result has acceptable units.

Solve

$$P = 745\ \text{mmHg} \times \frac{1\ \text{atm}}{760\ \text{mmHg}} = 0.980\ \text{atm}$$

$$V = ?$$

$$n = 13.7\ \text{g Cl}_2 \times \frac{1\ \text{mol Cl}_2}{70.91\ \text{g Cl}_2} = 0.193\ \text{mol Cl}_2$$

$$R = 0.08206\ \text{atm L mol}^{-1}\ \text{K}^{-1}$$

$$T = 45\ °\text{C} + 273 = 318\ \text{K}$$

Divide both sides of the ideal gas equation by P to solve for V.

$$\frac{\cancel{P}V}{\cancel{P}} = \frac{nRT}{P} \quad \text{and} \quad V = \frac{nRT}{P}$$

$$V = \frac{nRT}{P} = \frac{0.193\ \cancel{\text{mol}} \times 0.08206\ \cancel{\text{atm}}\ \text{L}\ \cancel{\text{mol}^{-1}}\ \cancel{\text{K}^{-1}} \times 318\ \cancel{\text{K}}}{0.980\ \cancel{\text{atm}}} = 5.14\ \text{L}$$

Assess

A useful check of the calculated result is to make certain the units cancel properly. In the setup above, all units cancel except for L, a unit of volume. Keep in mind that when canceling units, such a unit as mol^{-1} is the same as 1/mol. Thus, $\text{mol} \times \text{mol}^{-1} = 1$ and $\text{K} \times \text{K}^{-1} = 1$.

PRACTICE EXAMPLE A: What is the volume occupied by 20.2 g $NH_3(g)$ at −25°C and 752 mmHg?

PRACTICE EXAMPLE B: At what temperature will a 13.7 g Cl_2 sample exert a pressure of 0.993 bar when confined in a 7.50 L container?

EXAMPLE 6-5 Calculating a Gas Pressure with the Ideal Gas Equation

What is the pressure, in kilopascals, exerted by 1.00×10^{20} molecules of N_2 in a 305 mL flask at 175°C?

Analyze

We are given an amount of gas (in molecules), a volume (in mL), and a temperature (in °C). Before using these quantities in the ideal gas equation, we must express the amount in moles, the volume in liters, and the temperature in Kelvin. Include units throughout the calculation to ensure that the final result has acceptable units.

Solve

Because we seek a pressure in kilopascals, let us use the form of the ideal gas equation having

$$R = 8.3145\ \text{Pa m}^3\ \text{mol}^{-1}\ \text{K}^{-1}$$

The first step is to convert from molecules to moles of a gas, n.

$$n = 1.00 \times 10^{20}\ \text{molecules N}_2 \times \frac{1\ \text{mol N}_2}{6.022 \times 10^{23}\ \text{molecules N}_2}$$

$$= 0.000166\ \text{mol N}_2$$

(continued)

Convert from milliliters to liters and then to cubic meters (recall Figure 1-9).

$$V = 305\text{ mL} \times \frac{1\text{ L}}{1000\text{ mL}} \times \frac{1\text{ m}^3}{1000\text{ L}} = 3.05 \times 10^{-4}\text{ m}^3$$

Express gas temperature on the Kelvin scale.

$$T = 175°\text{C} + 273 = 448\text{ K}$$

Rearrange the ideal gas equation to the form $P = nRT/V$, and substitute the above data.

$$P = \frac{nRT}{V} = \frac{0.000166\text{ mol} \times 8.3145\text{ Pa m}^3\text{ mol}^{-1}\text{ K}^{-1} \times 448\text{ K}}{3.05 \times 10^{-4}\text{ m}^3}$$

$$= 2.03 \times 10^3\text{ Pa}$$

Finally, convert the pressure to the unit kilopascal.

$$P = 2.03 \times 10^3\text{ Pa} \times \frac{1\text{ kPa}}{1000\text{ Pa}} = 2.03\text{ kPa}$$

Assess

Again, we see from the cancellation of units above that only the desired unit—a pressure unit—remains.

PRACTICE EXAMPLE A: How many moles of He(g) are in a 5.00 L storage tank filled with helium at 10.5 atm pressure at 30.0 °C?

PRACTICE EXAMPLE B: How many molecules of $N_2(g)$ remain in an ultrahigh vacuum chamber of 3.45 m^3 volume when the pressure is reduced to 6.67×10^{-7} Pa at 25 °C?

sets of conditions. Here, the ideal gas equation must be applied twice—to an initial condition and a final condition. That is,

Initial condition (i)	*Final condition* (f)
$P_iV_i = n_iRT_i$	$P_fV_f = n_fRT_f$
$R = \dfrac{P_iV_i}{n_iT_i}$	$R = \dfrac{P_fV_f}{n_fT_f}$

The above expressions are equal to each other because each is equal to *R*.

$$\frac{P_iV_i}{n_iT_i} = \frac{P_fV_f}{n_fT_f} \qquad \textbf{(6.12)}$$

Expression (6.12) is called the **general gas equation**. It is often applied in cases in which one or two of the gas properties are held constant, and the equation can be simplified by eliminating these constants. For example, if a constant mass of gas is subject to changes in temperature, pressure, and volume, n_i and n_f cancel because they are equal (constant moles); thus we have

$$\frac{P_iV_i}{T_i} = \frac{P_fV_f}{T_f} \quad (n\text{ constant})$$

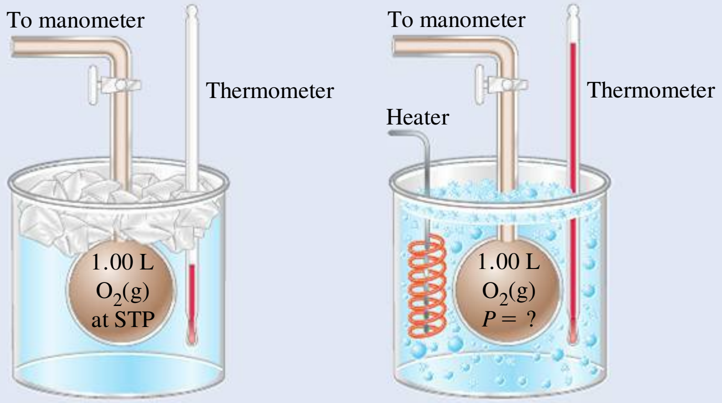
This equation is sometimes referred to as the *combined gas law*. In Example 6-6, both volume and mass are constant, and this establishes the simple relationship between gas pressure and temperature known as *Amontons's law*: The pressure of a fixed amount of gas confined to a fixed volume is directly proportional to the Kelvin temperature.

Using the Gas Laws

When confronted with a problem involving gases, students sometimes wonder which gas equation to use. Gas law problems can often be thought of in more than one way. When a problem involves a comparison of two gases or two states (initial and final) of a single gas, use the general gas equation (6.12) after eliminating any term (n, P, T, V) that remains constant. Otherwise, use the ideal gas equation (6.11).

EXAMPLE 6-6 Applying the General Gas Equation

The situation pictured in Figure 6-10(a) is changed to that in Figure 6-10(b). What is the gas pressure in Figure 6-10(b)?



(a) Ice bath **(b)** Boiling water

▲ FIGURE 6-10
Pressure of a gas as a function of temperature—Example 6-6 visualized
The amount of gas and volume are held constant. **(a)** 1.00 L $O_2(g)$ at STP; **(b)** 1.00 L $O_2(g)$ at 100 °C.

Analyze

Identify the quantities in the general gas equation that remain constant. Cancel out these quantities and solve the equation that remains.

Solve

In this case, the amount of O_2 is constant $(n_i = n_f)$ and the volume is constant $(V_i = V_f)$.

$$\frac{P_i \cancel{V_i}}{\cancel{n_i} T_i} = \frac{P_f \cancel{V_f}}{\cancel{n_f} T_f} \quad \text{and} \quad \frac{P_i}{T_i} = \frac{P_f}{T_f} \quad \text{and} \quad P_f = P_i \times \frac{T_f}{T_i}$$

Since $P_i = 1.00$ bar, $T_i = 273$ K, and $T_f = 373$ K, then

$$P_f = 1.00 \text{ bar} \times \frac{373 \text{ K}}{273 \text{ K}} = 1.37 \text{ bar}$$

Assess

We can base our check on a qualitative, intuitive understanding of what happens when a gas is heated in a closed container. Its pressure increases (possibly to the extent that the container bursts). If, by error, we had used the ratio of temperatures 273 K/373 K, the final pressure would have been less than 1.00 bar—an impossible result.

PRACTICE EXAMPLE A: A 1.00 mL sample of $N_2(g)$ at 36.2 °C and 2.14 atm is heated to 37.8 °C, and the pressure changed to 1.02 atm. What volume does the gas occupy at this final temperature and pressure?

PRACTICE EXAMPLE B: Suppose that in Figure 6-10 we want the pressure to remain at 1.00 bar when the $O_2(g)$ is heated to 100 °C. What mass of $O_2(g)$ must we release from the flask?

6-4 Applications of the Ideal Gas Equation

Although the ideal gas equation can always be used as it was presented in equation (6.11), it is useful to recast it into slightly different forms for some applications. We will consider two such applications in this section: determination of molar masses and gas densities.

Molar Mass Determination

If we know the volume of a gas at a fixed temperature and pressure, we can solve the ideal gas equation for the amount of the gas in moles. Because the number of moles of gas (n) is equal to the mass (m) of gas divided by the molar mass (M), if we know the mass and number of moles of gas, we can solve the expression $n = m/M$ for the molar mass, M. An alternative is to make the substitution $n = m/M$ directly into the ideal gas equation.

$$PV = \frac{mRT}{M} \tag{6.13}$$

EXAMPLE 6-7 Determining a Molar Mass with the Ideal Gas Equation

Propylene is an important commercial chemical (about ninth in the amount produced among manufactured chemicals) used in the synthesis of other organic chemicals and in production of plastics (polypropylene). A glass vessel weighs 40.1305 g when clean, dry, and evacuated; it weighs 138.2410 g when filled with water at 25.0 °C (density of water $= 0.9970$ g/mL) and 40.2959 g when filled with propylene gas at 740.3 mmHg and 24.0 °C. What is the molar mass of propylene?

Analyze

We are given a pressure (in mmHg), a temperature (in °C), and information that will enable us to determine the amount of gas (in grams) and the volume of the vessel. If we express these quantities in Kelvin, atmospheres, moles, and liters, respectively, then we can use equation (6.13), with $R = 0.08206$ atm L K^{-1} mol^{-1}, to calculate the molar mass of the gas.

Solve

First determine the mass of water required to fill the vessel.

$$\text{mass of water to fill vessel} = 138.2410\ \text{g} - 40.1305\ \text{g} = 98.1105\ \text{g}$$

Use the density of water in a conversion factor to obtain the volume of water (and hence, the volume of the glass vessel).

$$\text{volume of water (volume of vessel)} = 98.1105\ \text{g}\ H_2O \times \frac{1\ \text{mL}\ H_2O}{0.9970\ \text{g}\ H_2O} = 98.41\ \text{mL} = 0.09841\ \text{L}$$

The mass of the gas is the difference between the weight of the vessel filled with propylene gas and the weight of the empty vessel.

$$\text{mass of gas} = 40.2959\ \text{g} - 40.1305\ \text{g} = 0.1654\ \text{g}$$

The values of temperature and pressure are given.

$$T = 24.0\ °\text{C} + 273.15 = 297.2\ \text{K}$$

$$P = 740.3\ \text{mmHg} \times \frac{1\ \text{atm}}{760\ \text{mmHg}} = 0.9741\ \text{atm}$$

Substitute data into the rearranged version of equation (6.13).

$$M = \frac{mRT}{PV} = \frac{0.1654\ \text{g} \times 0.08206\ \cancel{\text{atm}}\ \cancel{\text{L}}\ \text{mol}^{-1}\ \cancel{\text{K}^{-1}} \times 297.2\ \cancel{\text{K}}}{0.9741\ \cancel{\text{atm}} \times 0.09841\ \cancel{\text{L}}}$$

$$= 42.08\ \text{g mol}^{-1}$$

Assess

Cancellations leave the units g and mol^{-1}. The unit g mol^{-1} or g/mol is that for molar mass, the quantity we are seeking. We can use another approach to solving this problem. We can substitute the pressure (0.9741 atm), temperature (297.2 K), and volume (0.09841 L) into the ideal gas equation to calculate the number of moles in the gas sample (0.003931 mol). Because the sample contains 0.003931 mol and has a mass of 0.165 g, the molar mass is 0.165 g/0.003931 mol $= 42.0$ g mol^{-1}. The advantage of this alternative approach is that it makes use of only the ideal gas equation; you do not have to memorize or derive equation (6.13) for the cases when you might need it.

PRACTICE EXAMPLE A: The same glass vessel used in Example 6-7 is filled with an unknown gas at 772 mmHg and 22.4 °C. The gas-filled vessel weighs 40.4868 g. What is the molar mass of the gas?

PRACTICE EXAMPLE B: A 1.27 g sample of an oxide of nitrogen, believed to be either NO or N_2O, occupies a volume of 1.07 L at 25 °C and 737 mmHg. Which oxide is it?

Equation (6.13) is used to determine a molar mass in Example 6-7, but note that the equation can also be used when the molar mass of a gas is known and the mass of a particular sample of the gas is sought.

Suppose that we want to determine the formula of an unknown hydrocarbon. With combustion analysis we can establish the mass percent composition, and from this, we can determine the empirical formula. The method of Example 6-7 gives us a molar mass, in g mol^{-1}, which is numerically equal to the molecular mass, in u. This is all the information we need to establish the true molecular formula of the hydrocarbon (see Exercise 96).

Gas Densities

To determine the density of a gas, we can start with the density equation, $d = m/V$. Then we can express the mass of gas as the product of the number of moles of gas and the molar mass: $m = n \times M$. This leads to

$$d = \frac{m}{V} = \frac{n \times M}{V} = \frac{n}{V} \times M$$

Now, with the ideal gas equation, we can replace n/V by its equivalent, P/RT, to obtain

$$d = \frac{m}{V} = \frac{MP}{RT} \qquad \textbf{(6.14)}$$

The density of a gas at STP can easily be calculated by dividing its molar mass by the molar volume (22.7 L/mol). For $O_2(g)$ at STP, for example, the density is 32.0 g/22.7 L = 1.41 g/L. Equation (6.14) can be used for other conditions of temperature and pressure.

KEEP IN MIND

that gas densities are typically much smaller than those of liquids and solids. Gas densities are usually expressed in grams per *liter* rather than grams per *milliliter*.

EXAMPLE 6-8 Using the Ideal Gas Equation to Calculate a Gas Density

What is the density of oxygen gas (O_2) at 298 K and 0.987 atm?

Analyze

The gas is identified, and therefore the molar mass can be calculated. We are given a temperature in Kelvin and a pressure in atmospheres, so we can use equation (6.14) directly with $R = 0.08206 \text{ atm L K}^{-1} \text{ mol}^{-1}$.

Solve

The molar mass of O_2 is 32.0 g mol^{-1}. Now, use equation (6.14).

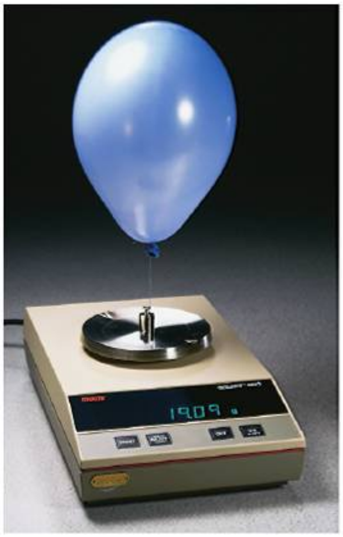
$$d = \frac{m}{V} = \frac{MP}{RT} = \frac{32.00 \text{ g mol}^{-1} \times 0.987 \text{ atm}}{0.08206 \text{ atm L mol}^{-1} \text{ K}^{-1} \times 298 \text{ K}} = 1.29 \text{ g/L}$$

Assess

We can solve this problem in another way. To calculate the density of a gas at a certain temperature and pressure, use a 1.00 L sample of the gas. The mass of a 1.00 L sample is equal to the density in grams per liter. To calculate the mass of a 1.00 L sample, first use the ideal gas equation to calculate the number of moles in the sample, and then convert the amount in moles to an amount in grams by using the molar mass as a conversion factor. In the present case, the amount of $O_2(g)$ in a 1.00 L sample at 0.987 atm and 298 K is 0.0404 mol O_2, or 1.29 g O_2. Because a 1.00 L sample of O_2 at this temperature and pressure has a mass of 1.29 g, the density is 1.29 g/L.

PRACTICE EXAMPLE A: What is the density of helium gas at 298 K and 0.987 atm? Based on your answer, explain why we can say that helium is "lighter than air."

PRACTICE EXAMPLE B: The density of a sample of gas is 1.00 g/L at 745 mmHg and 109 °C. What is the molar mass of the gas?



▲ FIGURE 6-11
The helium-filled balloon exerts a lifting force on the 20.00 g weight, so that the balloon and the weight together weigh only 19.09 g.

The density of gases differs from that of solids and liquids in two important ways.

1. Gas densities depend strongly on pressure and temperature, increasing as the gas pressure increases and decreasing as the temperature increases. Densities of liquids and solids also depend somewhat on temperature, but they depend far less on pressure.
2. The density of a gas is directly proportional to its molar mass. No simple relationship exists between density and molar mass for liquids and solids.

An important application of gas densities is in establishing conditions for lighter-than-air balloons. A gas-filled balloon will rise in the atmosphere only if the density of the gas is less than that of the surrounding air. Because gas densities are directly proportional to molar masses, the lower the molar mass of the gas, the greater its lifting power. The lowest molar mass is that of hydrogen, but hydrogen is flammable and forms explosive mixtures with air. The explosion of the dirigible *Hindenburg* in 1937 spelled the end to transoceanic travel by hydrogen-filled airships. Now, airships, such as the Goodyear blimps, use helium, which has a molar mass only twice that of hydrogen (Fig. 6-11) but is inert. Hydrogen is still used for weather and other observational balloons.

Another alternative is to fill a balloon with *hot* air. Equation (6.14) indicates that the density of a gas is *inversely* proportional to temperature. Hot air is less dense than cold air. However, because the density of air decreases rapidly with altitude, there is a limit to how high a hot-air balloon or any gas-filled balloon can rise.

6-5 Gases in Chemical Reactions

Reactions involving gases as reactants or products (or both) are no strangers to us. We now have a new tool to apply to reaction stoichiometry calculations: the ideal gas equation. Specifically, we can now handle information about gases in terms of volumes, temperatures, and pressures, as well as by mass and amount in moles. A practical application is the nitrogen-forming reaction in an automobile air-bag safety system, which utilizes the rapid decomposition of sodium azide.

$$2\,\mathrm{NaN_3(s)} \xrightarrow{\Delta} 2\,\mathrm{Na(l)} + 3\,\mathrm{N_2(g)}$$

The essential components of the system are an ignition device and a pellet containing sodium azide and appropriate additives. When activated, the system inflates an air bag in 20 to 60 ms and converts Na(l) to a harmless solid residue.

For reactions involving gases, we can (1) use stoichiometric factors to relate the amount of a gas to amounts of other reactants or products, and (2) use the ideal gas equation to relate the amount of gas to volume, temperature, and pressure. In Example 6-9, we use this approach to determine the volume of $N_2(g)$ produced in a typical air-bag system.

Law of Combining Volumes

If the reactants and products involved in a stoichiometric calculation are gases, sometimes we can use a particularly simple approach. Consider this reaction.

$$2\,\mathrm{NO(g)} + \mathrm{O_2(g)} \longrightarrow 2\,\mathrm{NO_2(g)}$$
$$2\text{ mol NO(g)} + 1\text{ mol }\mathrm{O_2(g)} \longrightarrow 2\text{ mol }\mathrm{NO_2(g)}$$

EXAMPLE 6-9 Using the Ideal Gas Equation in Reaction Stoichiometry Calculations

What volume of N_2, measured at 735 mmHg and 26 °C, is produced when 75.0 g NaN_3 is decomposed?

$$2\,NaN_3(s) \xrightarrow{\Delta} 2\,Na(l) + 3\,N_2(g)$$

Analyze

The following conversions are required.

$$g\,NaN_3 \longrightarrow mol\,NaN_3 \longrightarrow mol\,N_2 \longrightarrow L\,N_2$$

The molar mass of NaN_3 is used for the first conversion. The second conversion makes use of a stoichiometric factor constructed from the coefficients of the chemical equation. The ideal gas equation is used to complete the final conversion.

Solve

$$?\,mol\,N_2 = 75.0\,g\,NaN_3 \times \frac{1\,mol\,NaN_3}{65.01\,g\,NaN_3} \times \frac{3\,mol\,N_2}{2\,mol\,NaN_3} = 1.73\,mol\,N_2$$

$$P = 735\,mmHg \times \frac{1\,atm}{760\,mmHg} = 0.967\,atm$$

$$V = ?$$

$$n = 1.73\,mol$$

$$R = 0.08206\,atm\,L\,mol^{-1}\,K^{-1}$$

$$T = 26\,°C + 273 = 299\,K$$

$$V = \frac{nRT}{P} = \frac{1.73\,mol \times 0.08206\,atm\,L\,mol^{-1}\,K^{-1} \times 299\,K}{0.967\,atm} = 43.9\,L$$

Assess

75.0 g NaN_3 is slightly more than one mole ($M \approx 65$ g/mol). From this amount of NaN_3 we should expect a little more than 1.5 mol $N_2(g)$. At 0 °C and 1 atm, 1.5 mol $N_2(g)$ would occupy a volume of $1.5 \times 22.4 = 33.6$ L. Because the temperature is higher than 0 °C and the pressure is lower than 1 atm, the sample should have a volume somewhat greater than 33.6 L.

PRACTICE EXAMPLE A: How many grams of NaN_3 are needed to produce 20.0 L of $N_2(g)$ at 30.0 °C and 776 mmHg?

PRACTICE EXAMPLE B: How many grams of Na(l) are produced per liter of $N_2(g)$ formed in the decomposition of sodium azide if the gas is collected at 25 °C and 1.0 bar?

Suppose the gases are compared at the same T and P. Under these conditions, one mole of gas occupies a particular volume, call it V liters; two moles of gas occupy $2V$ liters; and so on.

$$2\,V\,L\,NO(g) + V\,L\,O_2(g) \longrightarrow 2\,V\,L\,NO_2(g)$$

If we divide each coefficient by V, we get the following result:

$$2\,L\,NO(g) + 1\,L\,O_2(g) \longrightarrow 2\,L\,NO_2(g)$$

Thus, the volume ratio of the gases consumed and produced in a chemical is the same as the mole ratio, provided the volumes are all measured at the same temperature and pressure.

What we have just done is to develop, in modern terms, Gay-Lussac's **law of combining volumes**. We previewed this law on page 201 by suggesting that the volumes of gases involved in a reaction are in the ratio of small whole numbers. The small whole numbers are simply the stoichiometric coefficients in the balanced equation. We apply this law in Example 6-10.

EXAMPLE 6-10 Applying the Law of Combining Volumes

Zinc blende, ZnS, is the most important zinc ore. Roasting (strong heating) of ZnS in oxygen is the first step in the commercial production of zinc.

$$2\,\text{ZnS(s)} + 3\,\text{O}_2\text{(g)} \xrightarrow{\Delta} 2\,\text{ZnO(s)} + 2\,\text{SO}_2\text{(g)}$$

What volume of $SO_2(g)$ can be obtained from 1.00 L $O_2(g)$ and excess ZnS(s)? Both gases are measured at 25 °C and 745 mmHg.

Analyze

The reactant and product being compared are both gases, and both are at the same temperature and pressure. Therefore, we can use the law of combining volumes and treat the coefficients in the balanced chemical equation as if they had units of liters.

Solve

The stoichiometric factor (shown below in blue) converts from L $O_2(g)$ to L $SO_2(g)$.

$$?\,\text{L SO}_2\text{(g)} = 1.00\,\text{L O}_2\text{(g)} \times \frac{2\,\text{L SO}_2\text{(g)}}{3\,\text{L O}_2\text{(g)}} = 0.667\,\text{L SO}_2\text{(g)}$$

Assess

Some students would solve this problem by using the following sequence of conversions: L $O_2 \longrightarrow$ mol $O_2 \longrightarrow$ mol $SO_2 \longrightarrow$ L SO_2. This approach is acceptable but not as simple as the approach we used.

PRACTICE EXAMPLE A: The first step in making nitric acid is to convert ammonia to nitrogen monoxide. This is done under conditions of high temperature and in the presence of a platinum catalyst. What volume of $O_2(g)$ is consumed per liter of NO(g) formed?

$$4\,\text{NH}_3\text{(g)} + 5\,\text{O}_2\text{(g)} \xrightarrow[850\,^\circ\text{C}]{\text{Pt}} 4\,\text{NO(g)} + 6\,\text{H}_2\text{O(g)}$$

PRACTICE EXAMPLE B: If all gases are measured at the same temperature and pressure, what volume of $NH_3(g)$ is produced when 225 L $H_2(g)$ are consumed in the reaction $N_2(g) + H_2(g) \longrightarrow NH_3(g)$ (not balanced)?

6-6 CONCEPT ASSESSMENT

Would the answer in Example 6-10 be greater than, less than, or equal to 0.677 L if (a) both gases were measured at STP; (b) if the O_2 were measured at STP and the SO_2 were measured at 25 °C and 745 mmHg?

6-6 Mixtures of Gases

The simple gas laws, such as Boyle's and Charles's laws, were based on the behavior of air—a mixture of gases. So, the simple gas laws and the ideal gas equation apply to a *mixture* of nonreactive gases as well as to individual gases. Where possible, the simplest approach to working with gaseous mixtures is just to use for the value of n the *total* number of moles of the gaseous mixture (n_{tot}).

As a specific example, consider a mixture of gases in a vessel of fixed volume V at temperature T. The total pressure of the mixture is determined by the total number of moles:

$$P_{\text{tot}} = \frac{n_{\text{tot}}RT}{V} \qquad (T\text{ constant}, V\text{ constant}) \qquad \textbf{(6.15)}$$

For fixed values of T and P, the total volume of a mixture of gases is also determined by the total number of moles:

$$V_{\text{tot}} = \frac{n_{\text{tot}}RT}{P} \qquad (T\text{ constant}, P\text{ constant})$$

EXAMPLE 6-11 Applying the Ideal Gas Equation to a Mixture of Gases

What is the pressure, in bar, exerted by a mixture of 1.0 g H_2 and 5.00 g He when the mixture is confined to a volume of 5.0 L at 20 °C?

Analyze

For fixed T and V, the total pressure of a mixture of gases is determined by the total number of moles of gas: $P_{\text{tot}} = n_{\text{tot}}RT/V$.

Solve

$$n_{\text{tot}} = \left(1.0\ \text{g H}_2 \times \frac{1\ \text{mol H}_2}{2.02\ \text{g H}_2}\right) + \left(5.00\ \text{g He} \times \frac{1\ \text{mol He}}{4.003\ \text{g He}}\right)$$

$$= 0.50\ \text{mol H}_2 + 1.25\ \text{mol He} = 1.75\ \text{mol gas}$$

$$P = \frac{1.75\ \text{mol} \times 0.0831\ \text{bar L mol}^{-1}\ \text{K}^{-1} \times 293\ \text{K}}{5.0\ \text{L}} = 8.5\ \text{bar}$$

Assess

It is also possible to solve this problem by starting from equation (6.12). Because 1 mol of ideal gas occupies 22.7 L at 0 °C and 1 bar, the pressure exerted by 1.75 mol of gas in a 5.0 L vessel at 293 K is $(1.75\ \text{mol}/1.00\ \text{mol}) \times (293\ \text{K}/273\ \text{K}) \times (22.7\ \text{L}/5.0\ \text{L}) \times 1.0\ \text{bar} = 8.5\ \text{bar}$.

PRACTICE EXAMPLE A: What will be the total gas pressure if 12.5 g Ne is added to the mixture of gases described in Example 6-11 and the temperature is then raised to 55 °C? [*Hint:* What is the new number of moles of gas? What effect does raising the temperature have on the pressure of a gas at constant volume?]

PRACTICE EXAMPLE B: 2.0 L of $O_2(g)$ and 8.0 L of $N_2(g)$, each at 0.00 °C and 1.00 atm, are mixed together. The nonreactive gaseous mixture is compressed to occupy 2.0 L at 298 K. What is the pressure exerted by this mixture?

John Dalton made an important contribution to the study of gaseous mixtures. He proposed that in a mixture, each gas expands to fill the container and exerts the same pressure (called its **partial pressure**) that it would if it were alone in the container. **Dalton's law of partial pressures** states that the total pressure of a mixture of gases is the sum of the partial pressures of the components of the mixture, as shown in Figure 6-12. For a mixture of gases, A, B, and so on,

$$P_{\text{tot}} = P_A + P_B + \cdots \qquad \textbf{(6.16)}$$

KEEP IN MIND

that when this expression is used, $V_A = V_B = \cdots = V_{\text{tot}}$

In a gaseous mixture of n_A moles of A, n_B moles of B, and so on, the volume each gas would individually occupy at a pressure equal to P_{tot} is

$$V_A = n_ART/P_{\text{tot}}; V_B = n_BRT/P_{\text{tot}}; \cdots$$

The total volume of the gaseous mixture is

$$V_{\text{tot}} = V_A + V_B \cdots$$

and the commonly used expression *percent by volume* is

$$\text{volume \% A} = \frac{V_A}{V_{\text{tot}}} \times 100\%; \text{Volume \% B} = \frac{V_B}{V_{\text{tot}}} \times 100\%; \cdots$$

KEEP IN MIND

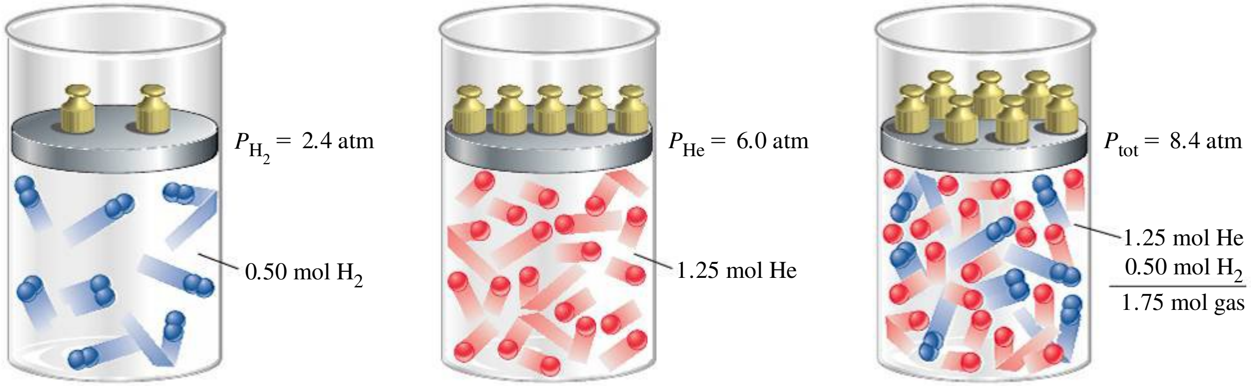
that when using this expression, $P_A = P_B = \cdots = P_{\text{tot}}$

We can derive a particularly useful expression from the following ratios,

$$\frac{P_A}{P_{\text{tot}}} = \frac{n_A(\cancel{RT/V_{\text{tot}}})}{n_{\text{tot}}(\cancel{RT/V_{\text{tot}}})} = \frac{n_A}{n_{\text{tot}}} \quad \text{and} \quad \frac{V_A}{V_{\text{tot}}} = \frac{n_A(\cancel{RT/P_{\text{tot}}})}{n_{\text{tot}}(\cancel{RT/P_{\text{tot}}})} = \frac{n_A}{n_{\text{tot}}}$$

which means that

$$\frac{n_A}{n_{\text{tot}}} = \frac{P_A}{P_{\text{tot}}} = \frac{V_A}{V_{\text{tot}}} = x_A \qquad \textbf{(6.17)}$$



(a) 5.0 L at 20 °C **(b)** 5.0 L at 20 °C **(c)** 5.0 L at 20 °C

▲ FIGURE 6-12
Dalton's law of partial pressures illustrated
The pressure of each gas is proportional to the number of moles of gas. The total pressure is the sum of the partial pressures of the individual gases.

The term n_A/n_{tot} is given a special name, the mole fraction of A, x_A. The **mole fraction** of a component in a mixture is the fraction of all the molecules in the mixture contributed by that component. The sum of all the mole fractions in a mixture is one.

As illustrated in Example 6-12, we can often think about mixtures of gases in more than one way.

EXAMPLE 6-12 Calculating the Partial Pressures in a Gaseous Mixture

What are the partial pressures of H_2 and He in the gaseous mixture described in Example 6-11?

Analyze

The ideal gas equation can be applied to each gas individually to obtain the partial pressure of each gas.

Solve

One approach involves a direct application of Dalton's law in which we calculate the pressure that each gas would exert if it were alone in the container.

$$P_{H_2} = \frac{n_{H_2} \times RT}{V} = \frac{0.50\text{ mol} \times 0.0821\text{ atm L mol}^{-1}\text{ K}^{-1} \times 293\text{ K}}{5.0\text{ L}} = 2.4\text{ atm}$$

$$P_{He} = \frac{n_{He} \times RT}{V} = \frac{1.25\text{ mol} \times 0.0821\text{ atm L mol}^{-1}\text{ K}^{-1} \times 293\text{ K}}{5.0\text{ L}} = 6.0\text{ atm}$$

Expression (6.17) gives us a simpler way to answer the question because we already know the number of moles of each gas and the total pressure from Example 6-11 ($P_{tot} = 8.4$ atm).

$$P_{H_2} = \frac{n_{H_2}}{n_{tot}} \times P_{tot} = \frac{0.50}{1.75} \times 8.4\text{ atm} = 2.4\text{ atm}$$

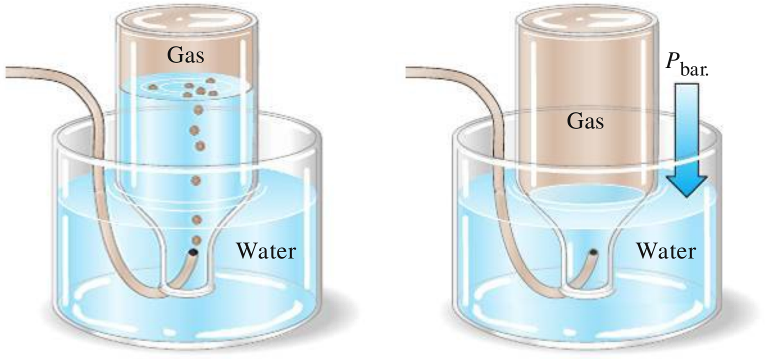
$$P_{He} = \frac{n_{He}}{n_{tot}} \times P_{tot} = \frac{1.25}{1.75} \times 8.4\text{ atm} = 6.0\text{ atm}$$

Assess

An effective way of checking an answer is to obtain the same answer when the problem is done in different ways, as was the case here.

PRACTICE EXAMPLE A: A mixture of 0.197 mol $CO_2(g)$ and 0.00278 mol $H_2O(g)$ is held at 30.0 °C and 2.50 atm. What is the partial pressure of each gas?

PRACTICE EXAMPLE B: The percent composition of air by volume is 78.08% N_2, 20.95% O_2, 0.93% Ar, and 0.036% CO_2. What are the partial pressures of these four gases in a sample of air at a barometric pressure of 748 mmHg?



▲ FIGURE 6-13
Collecting a gas over water
The bottle is filled with water and its open end is held below the water level in the container. Gas from a gas-generating apparatus is directed into the bottle. As gas accumulates in the bottle, water is displaced from the bottle into the container. To make the total gas pressure in the bottle equal to barometric pressure, the position of the bottle must be adjusted so that the water levels inside and outside the bottle are the same.

6-7 CONCEPT ASSESSMENT

Without doing a detailed calculation, state the outcome(s) you would expect in Figure 6-12(c) if an additional 0.50 mol H_2 were added to the cylinder in Figure 6-12(a): **(a)** the mole fraction of H_2 would double; **(b)** the partial pressure of He would remain the same; **(c)** the mole fraction of He would remain the same; **(d)** the total gas pressure would increase by 50%; **(e)** the total mass of gas would increase by 1.0 g.

The device pictured in Figure 6-13, a *pneumatic trough*, played a crucial role in isolating gases in the early days of chemistry. The method works, of course, only for gases that are insoluble in and do not react with the liquid being displaced. Many important gases meet these criteria. For example, H_2, O_2, and N_2 are all essentially insoluble in and unreactive with water.

A gas collected in a pneumatic trough filled with water is said to be *collected over water* and is "wet." It is a mixture of two gases—the desired gas and water vapor. The gas being collected expands to fill the container and exerts its partial pressure, P_{gas}. Water vapor, formed by the evaporation of liquid water, also fills the container and exerts a partial pressure, P_{H_2O}. The pressure of the water vapor depends only on the temperature of the water, as shown in Table 6.4.

According to Dalton's law, the total pressure of the wet gas is the sum of the two partial pressures. The total pressure can be made equal to the prevailing pressure of the atmosphere (barometric pressure) by adjusting the position of the bottle; thus we can write

$$P_{tot} = P_{bar.} = P_{gas} + P_{H_2O} \quad \text{or} \quad P_{gas} = P_{bar.} - P_{H_2O}$$

Once P_{gas} has been established, it can be used in stoichiometric calculations as illustrated in Example 6-13.

◀ Some early experimenters used mercury in the pneumatic trough so as to be able to collect gases soluble in water.

TABLE 6.4 Vapor Pressure of Water at Various Temperatures

Temperature, °C	Vapor Pressure, mmHg
15.0	12.79
17.0	14.53
19.0	16.48
21.0	18.65
23.0	21.07
25.0	23.76
30.0	31.82
50.0	92.51

EXAMPLE 6-13 Collecting a Gas over a Liquid (Water)

In the following reaction, 81.2 mL of $O_2(g)$ is collected over water at 23 °C and barometric pressure 751 mmHg. What mass of $Ag_2O(s)$ decomposed? (The vapor pressure of water at 23 °C is 21.1 mmHg.)

$$2\,Ag_2O(s) \longrightarrow 4\,Ag(s) + O_2(g)$$

(continued)

Analyze

The key concept is that the gas collected is wet, that is, a *mixture* of $O_2(g)$ and water vapor. Use $P_{bar.} = P_{O_2} + P_{H_2O}$ to calculate P_{O_2}, and then use the ideal gas equation to calculate the number of moles of O_2. The following conversions are used to complete the calculation: mol $O_2 \longrightarrow$ mol $Ag_2O \longrightarrow$ g Ag_2O.

Solve

$$P_{O_2} = P_{bar.} - P_{H_2O} = 751\ \text{mmHg} - 21.1\ \text{mmHg} = 730\ \text{mmHg}$$

$$P_{O_2} = 730\ \text{mmHg} \times \frac{1\ \text{atm}}{760\ \text{mmHg}} = 0.961\ \text{atm}$$

$$V = 81.2\ \text{mL} = 0.0812\ \text{L}$$

$$n = ?$$

$$R = 0.08206\ \text{atm L mol}^{-1}\ \text{K}^{-1}$$

$$T = 23\ ^\circ\text{C} + 273 = 296\ \text{K}$$

$$n = \frac{PV}{RT} = \frac{0.961\ \text{atm} \times 0.0812\ \text{L}}{0.08206\ \text{atm L mol}^{-1}\ \text{K}^{-1} \times 296\ \text{K}} = 0.00321\ \text{mol}$$

From the chemical equation we obtain a factor to convert from moles of O_2 to moles of Ag_2O. The molar mass of Ag_2O provides the final factor.

$$?\ \text{g}\ Ag_2O = 0.00321\ \text{mol}\ O_2 \times \frac{2\ \text{mol}\ Ag_2O}{1\ \text{mol}\ O_2} \times \frac{231.7\ \text{g}\ Ag_2O}{1\ \text{mol}\ Ag_2O} = 1.49\ \text{g}\ Ag_2O$$

Assess

The determination of the number of moles of O_2 in the sample is the key calculation. We can quickly estimate the number of moles of O_2 in the sample by using the fact that for typical conditions ($T \approx 298$ K, $P \approx 760$ mmHg), the molar volume of an ideal gas is about 24 L. The number of moles of gas (mostly O_2) in the sample is approximately 0.08 L/24 L $\approx$ 0.003 mol. This estimate is quite close to the value calculated above.

PRACTICE EXAMPLE A: The reaction of aluminum with hydrochloric acid produces hydrogen gas. The balanced chemical equation for the reaction is given below.

$$2\ Al(s) + 6\ HCl(aq) \longrightarrow 2\ AlCl_3(aq) + 3\ H_2(g)$$

If 35.5 mL of $H_2(g)$ is collected over water at 26 °C and a barometric pressure of 755 mmHg, how many moles of HCl must have been consumed? (The vapor pressure of water at 26 °C is 25.2 mmHg.)

PRACTICE EXAMPLE B: An 8.07 g sample of impure Ag_2O decomposes into solid silver and $O_2(g)$. If 395 mL $O_2(g)$ is collected over water at 25 °C and 749.2 mmHg barometric pressure, then what is the percent by mass of Ag_2O in the sample? The vapor pressure of water at 25 °C is 23.8 mmHg. What is the volume of gas collected?

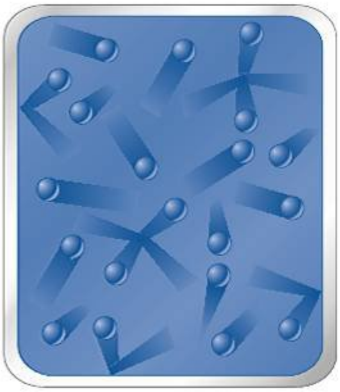
6-7 Kinetic-Molecular Theory of Gases

Let us apply some terminology that we introduced in Section 1-1 on the scientific method: The simple gas laws and the ideal gas equation are used to predict gas behavior. They are *natural laws*. To explain the gas laws, we need a *theory*. One theory developed during the mid-nineteenth century is called the **kinetic-molecular theory of gases**. It is based on the *model* illustrated in Figure 6-14 and outlined as follows.

- A gas is composed of a very large number of extremely small particles (molecules or, in some cases, atoms) in constant, random, straight-line motion.
- Molecules of a gas are separated by great distances. The gas is mostly empty space. (The molecules are treated as so-called point masses, as though they have mass but no volume.)
- Molecules collide only fleetingly with one another and with the walls of their container, and most of the time molecules are not colliding.
- There are assumed to be no forces between molecules except very briefly during collisions. That is, each molecule acts independently of all the others and is unaffected by their presence, except during collisions.

- Individual molecules may gain or lose energy as a result of collisions. In a collection of molecules at constant temperature, however, *the total energy remains constant*.

The validity of this model can be ascertained only by comparing predictions based on the model with experimental facts. As we will see, the predictions based on this model are consistent with several observed macroscopic properties.



▲ FIGURE 6-14
Visualizing molecular motion
Molecules of a gas are in constant motion and collide with one another and with the container wall.

Derivation of Boyle's Law

In this section, we will demonstrate that the kinetic-molecular theory of gases provides a satisfactory explanation of Boyle's law. Boyle's law was stated mathematically in equation (6.5):

$$PV = a$$

The value of a depends on the number, N, of molecules in the sample and the temperature, T. Because pressure is a force per unit area, the key to deriving equation (6.5) is in assessing the forces associated with molecules hitting the walls of the container. Let's focus on a molecule traveling along the x direction toward a wall perpendicular to its path. The speed of the molecule is denoted by u_x. The force exerted on the wall by the molecule depends on the following factors.

1. The *frequency* of molecular collisions—the number of collisions per second. The higher this frequency, the greater the total force on the wall of the container. Collision frequency increases with the number of molecules per unit volume and with molecular speeds.

$$\text{collision frequency} \propto (\text{molecular speed}) \times (\text{molecules per unit volume})$$
$$\text{collision frequency} \propto (u_x) \times (N/V)$$

2. The *momentum transfer*, or impulse. When a molecule hits the wall of a vessel, momentum is transferred as the molecule reverses direction. This momentum transfer is called an *impulse*. The magnitude of the impulse is directly proportional to the mass, m, of a molecule and its speed, u:

$$\text{impulse (momentum transfer)} \propto (\text{mass of particle}) \times (\text{molecular speed})$$
$$\text{impulse} \propto (mu_x)$$

The pressure of a gas (P) is the product of impulse and collision frequency. Thus, the complete proportionality expression for factors that affect pressure is

$$P \propto (mu_x) \times (u_x) \times (N/V) \propto (N/V)mu_x^2$$

At any instant, however, the molecules in a gas sample are traveling at different speeds. Therefore, we must replace u_x^2 in the expression above with the average value of u_x^2, which is denoted by $\overline{u_x^2}$. (In this context, the overbar reminds us that we are referring to the average value of u_x^2.) To better understand the concept of the average of the squares of speeds, consider five molecules with speeds 400, 450, 525, 585, and 600 m/s. We find the average of the squares of these speeds by squaring the speeds, adding the squares, and dividing by the number of particles, in this case five.

◀ The bar over a quantity means that the quantity can have a range of values and that the *average* value is intended.

$$\overline{u^2} = \frac{(400\ \text{m/s})^2 + (450\ \text{m/s})^2 + (525\ \text{m/s})^2 + (585\ \text{m/s})^2 + (600\ \text{m/s})^2}{5}$$
$$= 2.68 \times 10^5\ \text{m}^2/\text{s}^2$$

Thus the proportionality expression for pressure becomes

$$P \propto \frac{N}{V}m\overline{u_x^2}$$

We have one final factor to consider. There is absolutely nothing special about the x direction, so we should expect that $\overline{u_x^2} = \overline{u_y^2} = \overline{u_z^2} = \frac{1}{3}\overline{u^2}$, where the quantity $\overline{u^2} = \overline{u_x^2} + \overline{u_y^2} + \overline{u_z^2}$ is the average value of u^2 taking into account all the molecules, not just those moving in the x direction. $\overline{u^2}$ is called the mean-square speed. When we substitute $\frac{1}{3}\overline{u^2}$ for $\overline{u_x^2}$ in the expression above, we can also convert the expression into an equation because the factor of $\frac{1}{3}$ is, in fact, the proportionality constant. Thus, when all factors are properly considered, the result is

$$P = \frac{1}{3}\frac{N}{V}m\overline{u^2} \tag{6.18}$$

KEEP IN MIND

that *mean-square speed* is not the same as *square mean speed*. The mean, or average, speed is $(400 + 450 + 525 + 585 + 600)/5 = 512$ m/s. The square of this average, the square mean speed, is $(512 \text{ m/s})^2 = 2.62 \times 10^5 \text{ m}^2/\text{s}^2$. Mean square speed is the quantity that must be used in equation (6.18).

This is the basic equation of the kinetic-molecular theory of gases. We can rewrite equation (6.18) as $PV = \frac{1}{3}Nm\overline{u^2}$. If it is true that $\overline{u^2}$ depends only on temperature, then equation (6.18) is in fact a mathematical statement of Boyle's law. We will not prove mathematically that $\overline{u^2}$ depends only on temperature. However, the discussion of the next section should help to convince you that this is true. Equation (6.18) leads to some interesting results, as we see next.

Distribution of Molecular Speeds

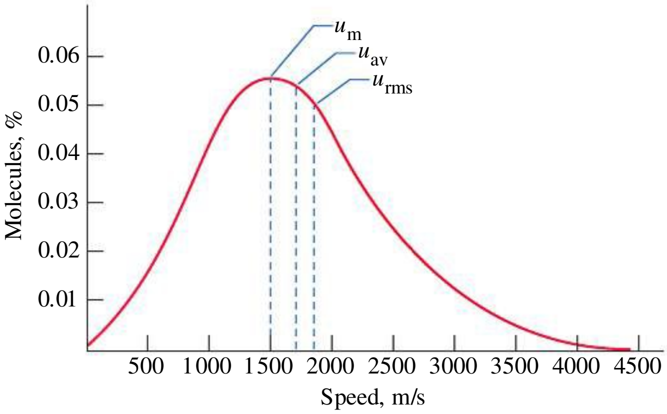
As pointed out in the derivation of Boyle's law, not all the molecules in a gas travel at the same speed. Because of the large number of molecules, we cannot know the speed of each molecule, but we can make a statistical prediction of how many molecules have a particular speed. The fraction, F, of molecules that have speed u is given by the following equation:

$$F(u) = 4\pi\left(\frac{M}{2\pi RT}\right)^{3/2} u^2 e^{-(Mu^2/2RT)}$$

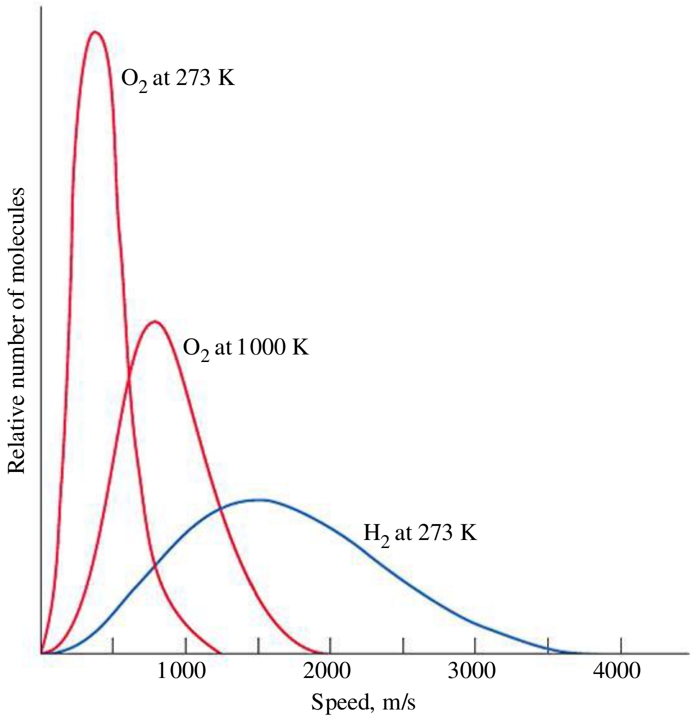
The equation above is called the Maxwell distribution of speeds, in honor of James Clerk Maxwell who derived it in 1860. We will not attempt to derive the Maxwell distribution, because to do so requires complex mathematics. Instead, we will accept it as valid and use it to help us understand how the distribution of speeds depends on molar mass, M, and temperature, T.

A plot of $F(u)$ versus u is shown in Figure 6-15 for a sample of $H_2(g)$ at 0 °C. The shape of the distribution is easily justified. The distribution depends on the product of two opposing factors: a factor that is proportional to u^2 and an exponential factor, $e^{-Mu^2/2RT}$. As u increases, the u^2 factor increases from a value of zero, while the exponential factor decreases from a value of one. The u^2 factor favors the presence of molecules with high speeds and is responsible for there being few molecules with speeds near zero. The exponential factor favors low speeds and limits the number of molecules that can have high

▶ Maxwell derived his equation in 1860, but it took until 1955 for direct experimental verification of this equation to be made. The experimental determination of the molecular speed distribution is described on page 221.



▶ FIGURE 6-15
Distribution of molecular speeds—hydrogen gas at 0 °C
The percentages of molecules with a certain speed are plotted as a function of the speed. Three different speeds are noted on the graph. The most probable speed is approximately 1500 m/s; the average speed is approximately 1700 m/s; and the root-mean-square speed is approximately 1800 m/s. Notice that $u_m < u_{av} < u_{rms}$.



◀ The area under each curve is the same. Each curve is for the same total number of molecules. Raising T (or lowering M) is like stretching a rubber graph. The same number of molecules are spread out over a wider range of speeds.

◀ FIGURE 6-16
Distribution of molecular speeds—the effect of mass and temperature
The relative numbers of molecules with a certain speed are plotted as a function of the speed. Note the effect of temperature on the distribution for oxygen molecules and the effect of mass—oxygen must be heated to a very high temperature to have the same distribution of speeds as does hydrogen at 273 K.

speeds. Because F is the product of these two opposing factors, F increases from a value of zero, reaches a maximum, and then decreases as u increases. Notice that the distribution is not symmetrical about its maximum.

In Figure 6-16, we show how the distribution of molecular speeds depends on temperature and molar mass. When we compare the distributions for $O_2(g)$ at 273 K and 1000 K, we see that the range of speeds broadens as the temperature increases and that the distribution shifts toward higher speeds. The distributions for $O_2(g)$ at 273 K and $H_2(g)$ at 273 K reveal that the lighter the gas, the broader the range of speeds.

Let us focus now on the three characteristic speeds identified in Figure 6-15. The most probable speed, or modal speed, is denoted by u_m; more molecules have this speed than any other speed. The average speed is denoted by u_{av}. The **root-mean-square speed**, u_{rms}, is obtained from the average of u^2: $u_{rms} = \sqrt{\overline{u^2}}$. The root-mean-square speed is of particular interest because we can use the value of u_{rms} to calculate the average kinetic energy, $\overline{e_k}$, of a collection of molecules.

The average kinetic energy of a collection of molecules, each having a mass $m = M/N_A$, is the average of $\frac{1}{2}mu^2$:

$$\overline{e_k} = \frac{1}{2}m\overline{u^2}$$

Since $u_{rms} = \sqrt{\overline{u^2}}$, then $u^2_{rms} = \overline{u^2}$ and the equation given above for $\overline{e_k}$ can be rewritten as

$$\overline{e_k} = \frac{1}{2}mu^2_{rms}$$

This result shows that we can calculate the average kinetic energy, $\overline{e_k}$, from the values of the molecular mass, m, and the root-mean-square speed, u_{rms}. All we need now is a simple way to calculate u_{rms}.

◀ If the postulates of the kinetic-molecular theory hold, a gas is automatically an ideal gas.

We can derive an equation for u_{rms} by combining equation (6.18) with the ideal gas equation. Consider 1 mol of an ideal gas. The number of molecules present is $N = N_A$ (Avogadro's number), and the ideal gas equation becomes $PV = RT$ (that is, $n = 1$ in the equation $PV = nRT$). First, replace N by N_A, and multiply both sides of equation (6.18) by V. This leads to

$$PV = \frac{1}{3}N_A m\overline{u^2} \qquad \textbf{(6.19)}$$

Next, replace PV by RT and multiply both sides of the equation by three.

$$3\,RT = N_A m\overline{u^2}$$

Now, note that the product $N_A m$ represents the mass of 1 mol of molecules, the molar mass, M.

$$3\,RT = M\overline{u^2}$$

Finally, solve for $\overline{u^2}$ and then, $\sqrt{\overline{u^2}}$ which is u_{rms}.

$$u_{rms} = \sqrt{\overline{u^2}} = \sqrt{\frac{3\,RT}{M}} \tag{6.20}$$

Equation (6.20) shows that u_{rms} of a gas is directly proportional to the square root of its Kelvin temperature and inversely proportional to the square root of its molar mass. From this we infer that, on average, (1) molecular speeds increase as the temperature increases, and (2) lighter gas molecules have greater speeds than do heavier ones.

To use equation (6.20) in calculating a root-mean-square speed, we must express the gas constant as

$$R = 8.3145\ \text{J mol}^{-1}\ \text{K}^{-1}$$

The joule has the units $\text{kg m}^2\,\text{s}^{-2}$, and consequently we must express molar mass in *kilograms* per mole, as we show in Example 6-14.

EXAMPLE 6-14 Calculating a Root-Mean-Square Speed

Which is the greater speed, that of a bullet fired from a high-powered M-16 rifle (2180 mi/h) or the root-mean-square speed of H_2 molecules at 25 °C?

Analyze

This is a straightforward application of equation (6.20). We must use SI units: $R = 8.3145\ \text{J K}^{-1}\,\text{mol}^{-1}$ and $M = 2.016 \times 10^{-3}\ \text{kg mol}^{-1}$. Recall that $1\ \text{J} = 1\ \text{kg m}^2\,\text{s}^{-2}$.

Solve

Determine u_{rms} of H_2 with equation (6.20).

$$u_{rms} = \sqrt{\frac{3 \times 8.3145\ \text{kg m}^2\,\text{s}^{-2}\,\text{mol}^{-1}\,\text{K}^{-1} \times 298\ \text{K}}{2.016 \times 10^{-3}\ \text{kg mol}^{-1}}}$$
$$= \sqrt{3.69 \times 10^6\ \text{m}^2/\text{s}^2} = 1.92 \times 10^3\ \text{m/s}$$

The remainder of the problem requires us either to convert 1.92×10^3 m/s to a speed in miles per hour, or 2180 mi/h to meters per second. Then we can compare the two speeds. When we do this, we find that 1.92×10^3 m/s corresponds to 4.29×10^3 mi/h. The root-mean-square speed of H_2 molecules at 25 °C is greater than the speed of the high-powered rifle bullet.

Assess

The cancellation of units yields a result for u_{rms} with the correct units (m/s). Also, Figure 6-15 shows that u_{rms} for H_2 is a bit greater than 1500 m/s at 273 K. At 298 K, u_{rms} should be slightly greater than it is at 273 K.

PRACTICE EXAMPLE A: Which has the greater root-mean-square speed at 25 °C, $NH_3(g)$ or $HCl(g)$? Calculate u_{rms} for the one with the greater speed.

PRACTICE EXAMPLE B: At what temperature are u_{rms} of H_2 and the speed of the M-16 rifle bullet given in Example 6-14 the same?

6-8 CONCEPT ASSESSMENT

Without performing an actual calculation, indicate which has the greater u_{rms}, He(g) at 1000 K or $H_2(g)$ at 250 K.

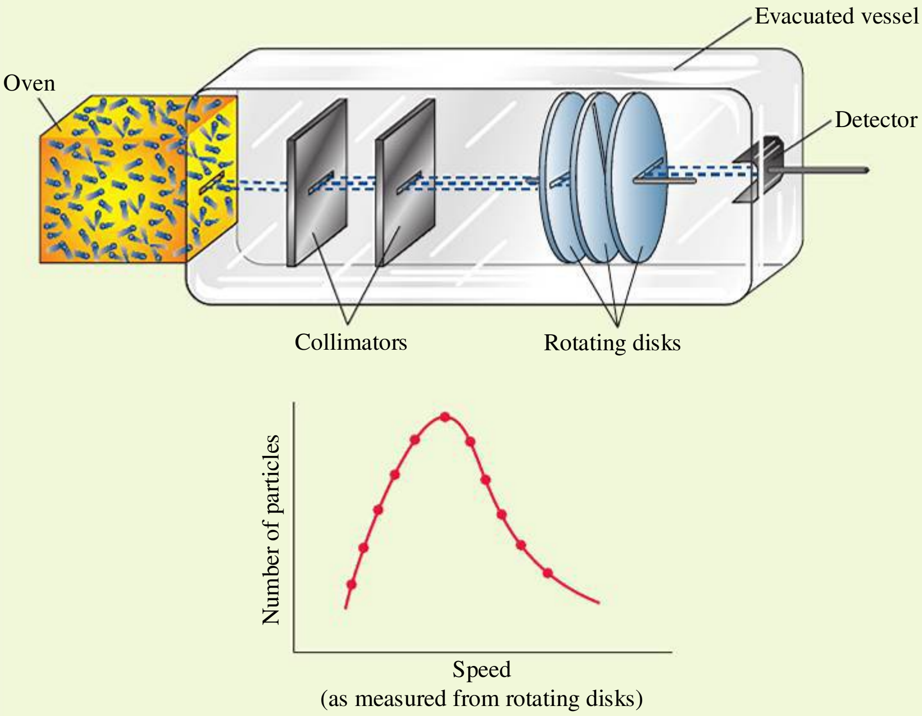
6-1 ARE YOU WONDERING...

How the distribution of molecular speeds can be demonstrated experimentally?

This can be done with the apparatus shown in Figure 6-17. An oven and attached evacuated chamber are separated by a wall with a small hole in it. Gas molecules are heated in the oven, emerge through the hole, and pass through a series of slits, called *collimators*, that herd the molecules into a beam. The number of molecules in the beam is kept low so that collisions between them will not disturb the beam.

The molecular beam passes through a series of rotating disks. Each disk has a slit cut in it. The slits on successive disks are offset from each other by a certain angle. A molecule passing through the first rotating disk will pass through the second disk only if its velocity is such that it arrives at the disk at the exact moment that the second slit appears. Thus, for a given rotation speed, only those molecules with the appropriate velocity can pass through the entire series of disks.

The number of molecules that pass through the disks and arrive at the detector is recorded for each chosen speed of rotation. The number of molecules for each speed of rotation is then plotted against the rotation speed. From the dimensions of the apparatus, the rotation speeds of the disks can be converted to molecular speeds, and a plot similar to the one in Figure 6-15 can be obtained.



▲ FIGURE 6-17
Distribution of molecular speeds—an experimental determination
Only those molecules with the correct speed to pass through all rotating disks will reach the detector, where they can be counted. By changing the rate of rotation of the disks, the complete distribution of molecular speeds can be determined.

The Meaning of Temperature

We can gain an important insight into the meaning of temperature by starting with equation (6.19), the basic equation of the kinetic-molecular theory written for 1 mol of gas.

We modify it slightly by replacing the fraction $\frac{1}{3}$ with the equivalent product $\frac{2}{3} \times \frac{1}{2}$.

$$PV = \frac{1}{3} N_A m\overline{u^2} = \frac{2}{3} N_A \left(\frac{1}{2} m\overline{u^2}\right)$$

The quantity $\left(\frac{1}{2} m\overline{u^2}\right)$ represents the average translational kinetic energy, $\overline{e_k}$, of a collection of molecules. When we make this substitution and replace PV by RT, we obtain

$$RT = \frac{2}{3} N_A \overline{e_k}$$

Then, we can solve this equation for e_k.

$$\overline{e_k} = \frac{3}{2}\left(\frac{RT}{N_A}\right) \qquad \textbf{(6.21)}$$

Because R and N_A are constants, equation (6.21) simply states that $\overline{e_k}$ = constant × T. This leads to an interesting new idea about temperature.

The Kelvin temperature (T) of a gas is directly proportional to the average translational kinetic energy ($\overline{e_k}$) of its molecules. **(6.22)**

The idea expressed in equation (6.22) also helps us to understand what is happening at the molecular level when objects with different temperatures are placed into contact with each other. Molecules in the hotter object have, on average, higher kinetic energies than do the molecules in the colder object. When the two objects are placed into contact with each other, molecules in the hotter object give up some of their kinetic energy through collisions with molecules in

6-2 ARE YOU WONDERING...

What's the lowest temperature we can reach?

Charles's law suggests that there is an absolute zero of temperature, 0 K, but can we attain this temperature? The answer is no, but we can come mighty close. Current attempts have resulted in temperatures as low as just a few nanokelvins! However, it is not simply a matter of putting some hot atoms in a refrigerator operating at 0 K. We have seen that the temperature of a sample of gas is proportional to the kinetic energy of the gas molecules; therefore, to cool atoms down we have to remove their kinetic energy. Simple cooling will not do the trick, because the refrigerator would always have to be at a lower temperature than the atoms being cooled.

Extremely cold atoms can be produced by removing their kinetic energy by stopping them in their tracks. This has been accomplished by using a technique called laser cooling, in which a laser light is directed at a beam of atoms, hitting them head-on and dramatically slowing them down. Once the atoms are cooled, intersecting beams of six lasers are used to reduce their energies still further. The sample of cold atoms is then trapped by a magnetic field for about 1 s. In 1995, a team at the University of Colorado successfully cooled a beam of rubidium (Rb) atoms to 1.7×10^{-7} K using this procedure. The coldest human-made temperature, 450 picokelvin, was reported by scientists from the Massachusetts Institute of Technology in 2003.*

*A. E. Leanhardt, T. A. Pasquini, M. Saba, A. Schirotzek, Y. Shin, D. Kielpinski, D. E. Pritchard, and W. Ketterle, Cooling Bose-Einstein Condensates Below 500 Picokelvin, *Science* 2003 vol 301, p. 1513.

the colder object. The transfer of energy continues until the average kinetic energies of the molecules in the two objects become equal, that is until the temperatures become equalized. Finally, the idea expressed in equation (6.22) provides a new way of looking at the absolute zero of temperature: *It is the temperature at which translational molecular motion should cease.*

6-8 Gas Properties Relating to the Kinetic-Molecular Theory

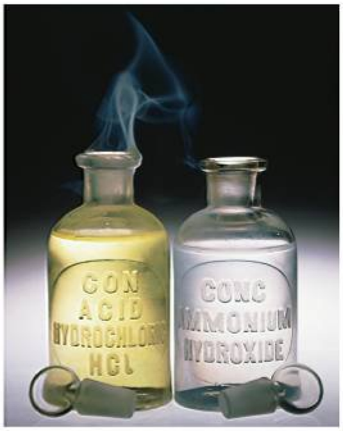
A molecular speed of 1500 m/s corresponds to 5400 km/h or about 3400 mi/h. From this, it might seem that a given gas molecule could travel very long distances over a very short time, but this is not quite the case. Every gas molecule undergoes collisions with other gas molecules and, as a result, keeps changing direction. Gas molecules follow a tortuous path, which slows them down in getting from one point to another. Still, the net rate at which gas molecules move in a particular direction does depend on their average speeds.

Diffusion is the migration of molecules as a result of random molecular motion. Figure 6-18 pictures a common diffusion seen in a chemistry laboratory. The diffusion of two or more gases results in an intermingling of the molecules and, in a closed container, soon produces a homogeneous mixture, as shown in Figure 6-19(a). A related phenomenon, **effusion**, is the escape of gas molecules from their container through a tiny orifice or pinhole. The effusion of a hypothetical mixture of two gases is suggested by Figure 6-19(b).

The rate at which effusion occurs is directly proportional to molecular speeds. That is, molecules with high speeds effuse faster than molecules with low speeds. Let us consider the effusion of two different gases at the same temperature and pressure. We can first compare effusion rates with root-mean-square speeds and then substitute expression (6.20) for these speeds.

$$\frac{\text{rate of effusion of A}}{\text{rate of effusion of B}} = \frac{(u_{\text{rms}})_{\text{A}}}{(u_{\text{rms}})_{\text{B}}} = \sqrt{\frac{3\,RT/M_{\text{A}}}{3\,RT/M_{\text{B}}}} = \sqrt{\frac{M_{\text{B}}}{M_{\text{A}}}} \qquad \textbf{(6.23)}$$

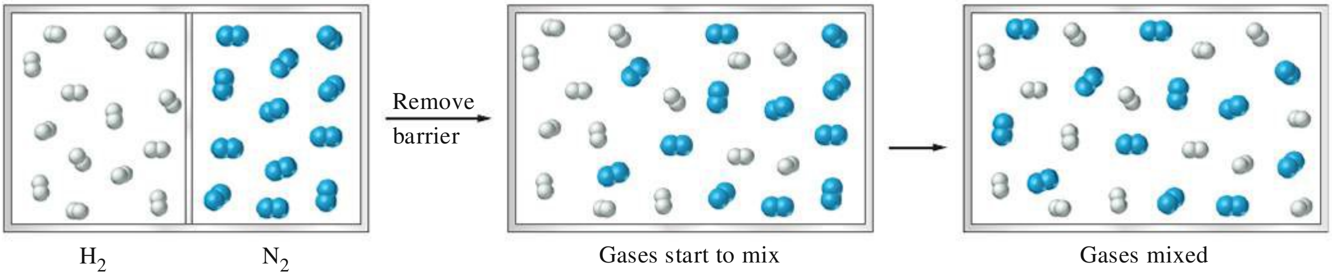
Any appropriate units (for example, g/s, mol/min) can be used to express a rate of effusion in equation (6.23) because in the ratio of two rates, the units



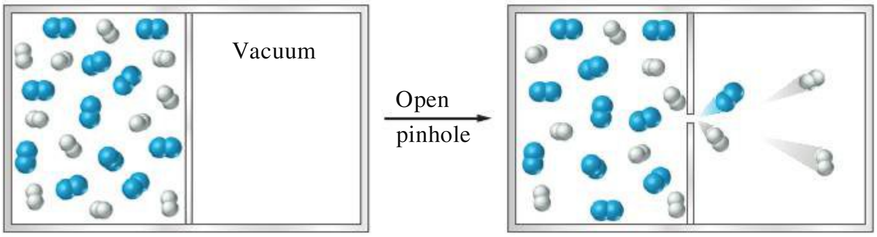
▲ FIGURE 6-18
Diffusion of $NH_3(g)$ and $HCl(g)$
$NH_3(g)$ escapes from $NH_3(aq)$ (but labeled ammonium hydroxide in this photograph), and $HCl(g)$ escapes from $HCl(aq)$. The gases diffuse toward each other, and, where they meet, a white cloud of ammonium chloride forms as a result of the following reaction:

$$NH_3(g) + HCl(g) \longrightarrow NH_4Cl(s).$$

Because of their greater average speed, NH_3 molecules diffuse faster than HCl. As a result, the cloud forms close to the mouth of the HCl(aq) container.



(a)



(b)

◀ FIGURE 6-19
Diffusion and effusion
(a) Diffusion is the passage of one substance through another. In this case, the H_2 initially diffuses farther through the N_2 because it is lighter, although eventually a complete random mixing occurs. **(b)** Effusion is the passage of a substance through a pinhole or porous membrane into a vacuum. In this case, the lighter H_2 effuses faster across the empty space than does the N_2.

cancel. Equation (6.23) is a kinetic-theory statement of a nineteenth-century law called **Graham's law**.

The rate of effusion of a gas is inversely proportional to the square root of its molar mass. **(6.24)**

Graham's law has serious limitations that you should be aware of. It can be used to describe effusion only for gases at very low pressures, so that molecules escape through an orifice individually, not as a jet of gas. Also, the orifice must be tiny so that no collisions occur as molecules pass through. Graham proposed his law in 1831 to describe the diffusion of gases, but the law actually does not apply to diffusion. Molecules of a diffusing gas undergo collisions with each other and with the gas into which they are diffusing. Some even move in the opposite direction to the net flow. Nevertheless, diffusion does occur, and gases of low molar mass do diffuse faster than those of higher molar mass. We cannot, however, use Graham's law to make quantitative predictions about rates of diffusion.

When compared at the same temperature, two different gases have the same value of $\overline{e}_\mathrm{k} = \frac{1}{2}m\overline{u^2}$. This means that molecules with a smaller mass (m) have a higher speed (u_rms). When effusion takes place under the restrictions described above, equation (6.23) can be used to determine which of two gases effuses faster, which does so in a shorter time, which travels farther in a given time, and so on. An effective way to do this is to note that in every case, a ratio of effusion rates, times, distances, and so on is equal to the square root of a ratio of molar masses, as indicated in equation (6.25).

$$\text{ratio of}\left\{\begin{array}{l}\text{molecular speeds}\\ \text{effusion rates}\\ \text{effusion times}\\ \text{distances traveled by molecules}\\ \text{amounts of gas effused}\end{array}\right. = \sqrt{\text{ratio of two molar masses}} \tag{6.25}$$

When using equation (6.25), first reason qualitatively and work out whether the ratio of properties should be greater or less than one. Then set up the ratio of molar masses accordingly. Examples 6-15 and 6-16 illustrate this line of reasoning.

6-9 CONCEPT ASSESSMENT

Which answer(s) is (are) true when comparing 1.0 mol $H_2(g)$ at STP and 0.50 mol He(g) at STP? The two gases have equal **(a)** average molecular kinetic energies; **(b)** root-mean-square speeds; **(c)** masses; **(d)** volumes; **(e)** densities; **(f)** effusion rates through the same orifice.

Applications of Diffusion

The diffusion of gases into one another has many practical applications. Natural gas and liquefied petroleum gas (LPG) are odorless; for commercial use, a small quantity of a gaseous organic sulfur compound, methyl mercaptan, CH_3SH, is added to them. The mercaptan has an odor that can be detected in parts per billion (ppb) or less. When a leak occurs, which can lead to asphyxiation or an explosion, we rely on the diffusion of this odorous compound for a warning.

During World War II, the Manhattan Project (the secret, U.S. government-run program for developing the atomic bomb) used a method called gaseous diffusion to separate the desired isotope ^{235}U from the predominant ^{238}U. The method is based on the fact that uranium hexafluoride is one of the few compounds of uranium that can be obtained as a gas at moderate temperatures.

EXAMPLE 6-15 Comparing Amounts of Gases Effusing Through an Orifice

If 2.2×10^{-4} mol $N_2(g)$ effuses through a tiny hole in 105 s, then how much $H_2(g)$ would effuse through the same orifice in 105 s?

Analyze

Let us reason qualitatively: H_2 molecules are lighter than N_2 molecules, so $H_2(g)$ should effuse faster than $N_2(g)$ when the gases are compared at the same temperature. Before we set the ratio

$$\frac{\text{mol } H_2 \text{ effused}}{\text{mol } N_2 \text{ effused}}$$

equal to $\sqrt{\text{ratio of molar masses}}$, we must ensure that the ratio of molar masses is *greater than 1*.

Solve

$$\frac{?\text{ mol } H_2}{2.2 \times 10^{-4}\text{ mol } N_2} = \sqrt{\frac{M_{N_2}}{M_{H_2}}} = \sqrt{\frac{28.014}{2.016}} = 3.728$$

$$?\text{ mol } H_2 = 3.728 \times 2.2 \times 10^{-4} = 8.2 \times 10^{-4}\text{ mol } H_2$$

Assess

We could have estimated the result before calculating it. Because the ratio of molar masses is approximately 14, the ratio of effusion rates is approximately $\sqrt{14}$, which is slightly smaller than 4. Therefore, H_2 will effuse almost 4 times as fast as N_2 and almost 4 times as much H_2 will effuse in the same period.

PRACTICE EXAMPLE A: In Example 6-15, how much $O_2(g)$ would effuse through the same orifice in 105 s?

PRACTICE EXAMPLE B: In Example 6-15, how long would it take for 2.2×10^{-4} mol H_2 to effuse through the same orifice as the 2.2×10^{-4} mol N_2?

EXAMPLE 6-16 Relating Effusion Times and Molar Masses

A sample of Kr(g) escapes through a tiny hole in 87.3 s. The same amount of an unknown gas escapes in 42.9 s under identical conditions. What is the molar mass of the unknown gas?

Analyze

Because the unknown gas effuses faster, it must have a smaller molar mass than Kr. Before we set the ratio

$$\frac{\text{effusion time for unknown}}{\text{effusion time for Kr}}$$

equal to $\sqrt{\text{ratio of two molar masses}}$, we must make sure the ratio of molar masses is smaller than one. Thus, the ratio of molar masses must be written with the molar mass of the lighter gas (the unknown gas) in the numerator.

Solve

$$\frac{\text{effusion time for unknown}}{\text{effusion time for Kr}} = \frac{42.9\text{ s}}{87.3\text{ s}} = \sqrt{\frac{M_{\text{unk}}}{M_{\text{Kr}}}} = 0.491$$

$$M_{\text{unk}} = (0.491)^2 \times M_{\text{Kr}} = (0.491)^2 \times 83.80 = 20.2\text{ g/mol}$$

Assess

Use the final result and work backward. The molar mass of the unknown is about 4 times as small as that of Kr. Because *effusion rate* $\propto 1/\sqrt{M}$, the unknown will effuse about $\sqrt{4} = 2$ times as fast as Kr. The effusion times show that the unknown does indeed effuse 2 times as fast as Kr.

PRACTICE EXAMPLE A: Under the same conditions as in Example 6-16, another unknown gas requires 131.3 s to escape. What is the molar mass of this unknown gas?

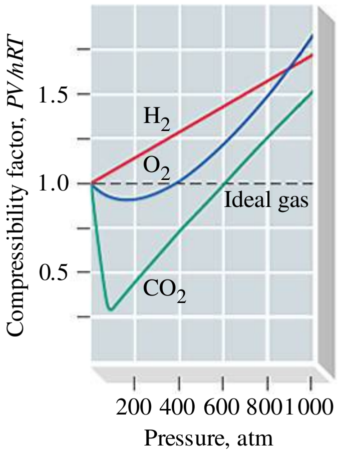
PRACTICE EXAMPLE B: Given all the same conditions as in Example 6-16, how long would it take for a sample of ethane gas, C_2H_6, to effuse?

When high-pressure $UF_6(g)$ is forced through a barrier having millions of submicroscopic holes per square centimeter, molecules containing the isotope ^{235}U pass through the barrier slightly faster than those containing ^{238}U, just as expected from expression (6.25), and therefore $UF_6(g)$ contains a slightly higher ratio of ^{235}U to ^{238}U than it did previously. The gas has become enriched in ^{235}U. Carrying this process through several thousand passes yields a product highly enriched in ^{235}U.

6-9 Nonideal (Real) Gases

The data in Table 6.2 provide us with clear evidence that real gases are not "ideal." We should comment briefly on the conditions under which a real gas is ideal or nearly so and what to do when the conditions lead to nonideal behavior. A useful measure of how much a gas deviates from ideal gas behavior is found in its compressibility factor. The *compressibility factor* of a gas is the ratio PV/nRT. From the ideal gas equation we see that for an ideal gas, $PV/nRT = 1$. For a real gas, the compressibility factor can have values that are significantly different from 1. Values of the compressibility factor are given in Table 6.5 for a variety of gases at 300 K and 10 bar. The data in Table 6.5 show that the deviations from ideal gas behavior can be small or large, depending on the gas. At 300 K and 10 bar, He, H_2, CO, N_2, and O_2 behave almost ideally $(PV/nRT \approx 1)$ but NH_3 and SF_6 do not $(PV/nRT \approx 0.88)$. In Figure 6-20, the compressibility factor is plotted as a function of pressure for three different gases. The principal conclusion from this plot is that all gases behave ideally at sufficiently low pressures, say, below 1 atm, but that deviations set in at increased pressures. At very high pressures, the compressibility factor is always greater than one.

Nonideal gas behavior can be described as follows: Boyle's law predicts that at very high pressures, a gas volume becomes extremely small and



▲ FIGURE 6-20
The behavior of real gases—compressibility factor as a function of pressure at 0 °C
Values of the compressibility factor less than one signify that intermolecular forces of attraction are largely responsible for deviations from ideal gas behavior. Values greater than one are found when the volume of the gas molecules themselves is a significant fraction of the total gas volume.

TABLE 6.5 van der Waals Constants and Compressibility Factors (at 10 bar and 300 K) for Various Gases

Gas	van der Waals Constants		Compressibility Factor
	a, bar L^2 mol^{-2}	*b*, L mol^{-1}	
H_2	0.2452	0.0265	1.006
He	0.0346	0.0238	1.005
Ideal gas	0	0	1

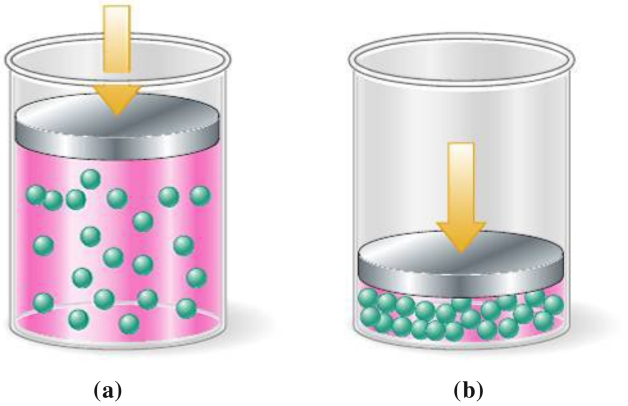
Source: van der Waals constants are from the *CRC Handbook of Chemistry and Physics*, 83rd ed., David R. Lide (ed.)., Boca Raton, FL: Taylor & Francis Group, 2002. Compressibility factors are calculated by using data from the National Institute of Standards and Technology (NIST) Chemistry WebBook, available online at http://webbook.nist.gov/chemistry/.

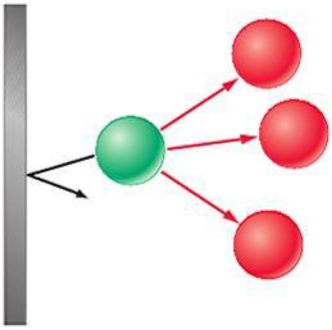
[a] At 10 bar and 300 K, C_3H_8 and SO_2 are liquids.



▲ FIGURE 6-21
The effect of finite molecular size
In **(a)**, a significant fraction of the container is empty space and the gas can still be compressed to a smaller volume. In **(b)**, the molecules occupy most of the available space. The volume of the system is only slightly greater than the total volume of the molecules.

approaches zero. This cannot be, however, because the molecules themselves occupy space and are practically incompressible, as suggested in Figure 6-21. Because of the finite size of the molecules, the PV product at high pressures is larger than predicted for an ideal gas, and the compressibility factor is greater than one. Another consideration is that intermolecular forces exist in gases. Figure 6-22 shows that because of attractive forces between the molecules, the force of the collisions of gas molecules with the container walls is less than expected for an ideal gas. Intermolecular forces of attraction account for compressibility factors of less than one. These forces become increasingly important at low temperatures, where translational molecular motion slows down. To summarize:

- Gases tend to behave *ideally* at *high temperatures* and *low pressures*.
- Gases tend to behave *nonideally* at *low temperatures* and *high pressures*.



▲ FIGURE 6-22
Intermolecular forces of attraction
Attractive forces of the red molecules for the green molecule cause the green molecule to exert less force when it collides with the wall than if these attractions did not exist.

The van der Waals Equation

A number of equations can be used for real gases, equations that apply over a wider range of temperatures and pressures than the ideal gas equation. Such equations are not as general as the ideal gas equation. They contain terms that have specific, but different, values for different gases. Such equations must correct for the volume associated with the molecules themselves and for intermolecular forces of attraction. Of all the equations that chemists use for modeling the behavior of real gases, the **van der Waals equation**, equation (6.26), is the simplest to use and interpret.

◀ The van der Waals equation reproduces the observed behavior of gases with moderate accuracy. It is most accurate for gases comprising approximately spherical molecules that have small dipole moments. We will discuss molecular shapes and dipole moments in Chapter 10.

$$\left(P + \frac{an^2}{V^2}\right)(V - nb) = nRT \qquad \textbf{(6.26)}$$

The equation incorporates two molecular parameters, a and b, whose values vary from molecule to molecule, as shown in Table 6.5.

The van der Waals equation and the ideal gas equation both have the form *pressure factor* $\times$ *volume factor* $= nRT$. The van der Waals equation uses a modified pressure factor, $P + an^2/V^2$, in place of P and a modified volume factor, $V - nb$, in place of V. In the modified volume factor, the term nb accounts for the volume of the molecules themselves. The parameter b is called the *excluded volume per mole,* and, to a rough approximation, it is the volume that one mole of gas occupies when it condenses to a liquid. Because the molecules are not point masses, the volume of the container must be no smaller than nb, and the volume available for molecular motion is $V - nb$. As suggested in Figure 6-21(b), the volume available for molecular motion is quite small at high pressures.

To explain the significance of the term an^2/V^2 in the modified pressure factor, it is helpful to solve equation (6.26) for P:

$$P = \frac{nRT}{V - nb} - \frac{an^2}{V^2}$$

Provided V is not too small, the first term in the equation above is approximately equal to the pressure exerted by an ideal gas: $nRT/(V - nb) \approx nRT/V = P_{\text{ideal}}$. The equation given above for P predicts that the pressure exerted by a real gas will be less than that of an ideal gas. Figure 6-22 illustrates why. Because of attractive forces, molecules near the container walls are attracted toward the molecules behind them; as a result, the gas exerts less force on the container walls. The term an^2/V^2 takes into account the decrease in pressure caused by intermolecular attractions. In 1873, the Dutch physicist Johannes van der Waals reasoned that the decrease in pressure caused by intermolecular attractions should be proportional to the square of the concentration, and so the decrease in pressure is represented in the form an^2/V^2. The proportionality constant, a, provides a measure of how strongly the molecules attract each other.

▶ In Chapter 12, we will examine intermolecular forces of attraction in greater detail and establish why the strength of the attractive intermolecular forces increases as the sizes of the molecules increase.

A close examination of Table 6.5 shows that the values of both a and b increase as the sizes of the molecules increase. The smaller the values of a and b, the more closely the gas resembles an ideal gas. Deviations from ideality, as measured by the compressibility factor, become more pronounced as the values of a and b increase. In Example 6-17 we calculate the pressure of a real gas by using the van der Waals equation. Solving the equation for either n or V is more difficult, however (see Exercise 121).

EXAMPLE 6-17 Using the van der Waals Equation to Calculate the Pressure of a Gas

Use the van der Waals equation to calculate the pressure exerted by 1.00 mol $Cl_2(g)$ confined to a volume of 2.00 L at 273 K. The value of $a = 6.49\ \text{L}^2\ \text{atm mol}^{-2}$, and that of $b = 0.0562\ \text{L mol}^{-1}$.

Analyze

This is a straightforward application of equation (6.26). It is important to include units to make sure the units cancel out properly.

Solve

Solve equation (6.26) for P.

$$P = \frac{nRT}{V - nb} - \frac{n^2a}{V^2}$$

Then substitute the following values into the equation.

$$n = 1.00\ \text{mol};\ V = 2.00\ \text{L};\ T = 273\ \text{K};\ R = 0.08206\ \text{atm L mol}^{-1}\ \text{K}^{-1}$$

$$n^2a = (1.00)^2\ \text{mol}^2 \times 6.49\frac{\text{L}^2\ \text{atm}}{\text{mol}^2} = 6.49\ \text{L}^2\ \text{atm}$$

$$nb = 1.00\ \text{mol} \times 0.0562\ \text{L mol}^{-1} = 0.0562\ \text{L}$$

$$P = \frac{1.00\ \text{mol} \times 0.08206\ \text{atm L mol}^{-1}\ \text{K}^{-1} \times 273\ \text{K}}{(2.00 - 0.0562)\ \text{L}} - \frac{6.49\ \text{L}^2\ \text{atm}}{(2.00)^2\ \text{L}^2}$$

$$P = 11.5\ \text{atm} - 1.62\ \text{atm} = 9.9\ \text{atm}$$

Assess

The pressure calculated with the ideal gas equation is 11.2 atm. By including only the *b* term in the van der Waals equation, we get a value of 11.5 atm. Including the *a* term reduces the calculated pressure by 1.62 atm. Under the conditions of this problem, intermolecular forces of attraction are the main cause of the departure from ideal behavior. Although the deviation from ideality here is rather large, in problem-solving situations, you can generally assume that the ideal gas equation will give satisfactory results.

PRACTICE EXAMPLE A: Substitute $CO_2(g)$ for $Cl_2(g)$ in Example 6-17, given the values $a = 3.66\ L^2\ bar\ mol^{-2}$ and $b = 0.0427\ L\ mol^{-1}$. Which gas, CO_2 or Cl_2, shows the greater departure from ideal gas behavior? [*Hint:* For which gas do you find the greater difference in calculated pressures, first using the ideal gas equation and then the van der Waals equation?]

PRACTICE EXAMPLE B: Substitute $CO(g)$ for $Cl_2(g)$ in Example 6-17, given the values $a = 1.47\ L^2\ bar\ mol^{-2}$ and $b = 0.0395\ L\ mol^{-1}$. Including CO_2 from Practice Example 6-17A, which of the three gases—Cl_2, CO_2, or CO—shows the greatest departure from ideal gas behavior?

6-10 CONCEPT ASSESSMENT

Following are the measured densities at 20.0 °C and 1 atm pressure of three gases: O_2, 1.331 g/L; OF_2, 2.26 g/L; NO, 1.249 g/L. Arrange them in the order of increasing adherence to the ideal gas equation. [*Hint:* What property can you calculate and compare with a known value?]

MasteringCHEMISTRY www.masteringchemistry.com

The blanket of gases surrounding Earth forms our atmosphere. It not only protects us from harmful radiation but also plays an essential role in moving water, essential to life, from the oceans to the land. For a discussion of the regions and composition of Earth's atmosphere, go to the Focus On feature for Chapter 6 on the MasteringChemistry site.

Summary

6-1 Properties of Gases: Gas Pressure—A gas is described in terms of its **pressure**, temperature, volume, and amount. Gas pressure is most readily measured by comparing it with the pressure exerted by a liquid column, usually mercury (equation 6.2). The pressure exerted by a column of mercury in a **barometer** and called the **barometric pressure** is equal to the prevailing pressure of the atmosphere (Fig. 6-4). Other gas pressures can be measured with a **manometer** (Fig. 6-5). Pressure can be expressed in a variety of units (Table 6.1), including the SI units **pascal** (**Pa**) and **kilopascal** (**kPa**). Also commonly used are **bar**; **millimeter of mercury** (**mmHg**); **torr** (**Torr**), where 1 Torr = 1 mmHg; and **atmosphere** (**atm**), where 1 atm = 760 mmHg = 760 Torr.

6-2 The Simple Gas Laws—The most common simple gas laws are **Boyle's law** relating gas pressure and volume (equation 6.5, Fig. 6-6); **Charles's law** relating gas volume and temperature (equation 6.8, Fig. 6-7); and **Avogadro's law**, relating volume and amount of gas. Some important ideas that originate from the simple gas laws are the **Kelvin** (**absolute**) scale of temperature (equation 6.6), the **standard conditions of temperature and pressure** (**STP**), and the molar volume of a gas at STP—22.7 L/mol (expression 6.10).

6-3 Combining the Gas Laws: The Ideal Gas Equation and the General Gas Equation—The simple gas laws can be combined into the **ideal gas equation**, $PV = nRT$ (equation 6.11), where *R* is called the **gas constant**. A gas whose behavior can be predicted with this equation is known as an **ideal**, or **perfect, gas**. The ideal gas equation can be solved for any one of the variables when all the others are known. The **general gas equation** (equation 6.12) is a useful variant of the ideal gas equation for describing the behavior of a gas when certain variables are held constant and others are allowed to change.

6-4 Applications of the Ideal Gas Equation—An important application of the ideal gas equation is its use in determining molecular masses (equation 6.13) and gas densities (equation 6.14).

6-5 Gases in Chemical Reactions—Because it relates the volume of a gas at a given temperature and pressure to the amount of gas, the ideal gas equation often enters into stoichiometric calculations for reactions involving gases. In calculations based on the volumes of two gaseous reactants and/or products measured at the same temperature and pressure, the **law of combining volumes** is generally applicable.

6-6 Mixtures of Gases—The ideal gas equation applies to mixtures of ideal gases as well as to pure gases. The enabling principle, known as **Dalton's law of partial pressures**, is that each gas expands to fill the container, exerting the same pressure as if it were alone in the container (Fig. 6-12). The total pressure is the sum of these **partial pressures** (equation 6.16). A useful concept in dealing with mixtures of gases is that of **mole fraction**, the fraction of the molecules in a mixture contributed by each component (equation 6.17). In the common procedure of collecting a gas over water (Fig. 6-13), the particular gas being isolated is mixed with water vapor.

6-7 Kinetic-Molecular Theory of Gases—The **kinetic-molecular theory of gases** yields a basic expression (equation 6.18) from which other relationships can be established between the **root-mean-square speed** (u_{rms}) of molecules, temperature, and molar mass of a gas (equation 6.20), and the average molecular translational kinetic energy and Kelvin temperature (equation 6.21). An important aspect of the kinetic-molecular theory is the concept of a distribution of molecular speeds (Figs. 6-15 and 6-16).

6-8 Gas Properties Relating to the Kinetic-Molecular Theory—The **diffusion** and **effusion** of gases (Fig. 6-19) can be described by the kinetic-molecular theory. Using an approximation known as **Graham's law**, molar masses can be determined by measuring rates of effusion (equation 6.23).

6-9 Nonideal (Real) Gases—Because of finite molecular size and intermolecular forces of attraction (Figs. 6-21 and 6-22), real gases generally behave ideally only at high temperatures and low pressures. Other equations of state, such as the **van der Waals equation** (equation 6.26), take into account the factors causing nonideal behavior and often work when the ideal gas equation fails.

Integrative Example

Combustion of 1.110 g of a gaseous hydrocarbon yields 3.613 g CO_2 and 1.109 g H_2O, and no other products. A 0.288 g sample of the hydrocarbon occupies a volume of 131 mL at 24.8 °C and 753 mmHg. Write a plausible structural formula for a hydrocarbon corresponding to these data.

Analyze

Use the combustion data for the 1.110 g sample of hydrocarbon and the method of Example 3-6 on page 83 to determine the empirical formula. Use the $P - V - T$ data in equation (6.13) for the 0.288 g sample to determine the molar mass and molecular mass of the hydrocarbon. By comparing the empirical formula mass and the molecular mass, establish the molecular formula. Now write a structural formula consistent with the molecular formula.

Solve

Calculate the number of moles of C and H in the 1.110 g sample of hydrocarbon based on the masses of CO_2 and H_2O obtained in its combustion.

$$? \text{ mol C} = 3.613 \text{ g CO}_2 \times \frac{1 \text{ mol CO}_2}{44.01 \text{ g CO}_2} \times \frac{1 \text{ mol C}}{1 \text{ mol CO}_2} = 0.08209 \text{ mol C}$$

$$? \text{ mol H} = 1.109 \text{ g H}_2\text{O} \times \frac{1 \text{ mol H}_2\text{O}}{18.02 \text{ g H}_2\text{O}} \times \frac{2 \text{ mol H}}{1 \text{ mol H}_2\text{O}} = 0.1231 \text{ mol H}$$

Use these numbers of moles as the provisional subscripts in the formula.

$$C_{0.08209}H_{0.1231}$$

Divide each provisional subscript by the smaller of the two to obtain the empirical formula.

$$C_{\frac{0.08209}{0.08209}}H_{\frac{0.1231}{0.08209}}$$

$$CH_{1.500} = C_2H_3$$

To determine the molar mass, use a modified form of equation (6.13).

$$M = \frac{mRT}{PV} = \frac{0.288 \text{ g} \times 0.08206 \text{ atm L K}^{-1} \text{ mol}^{-1} \times (24.8 + 273.2) \text{ K}}{(753 \text{ mmHg} \times 1 \text{ atm}/760 \text{ mmHg}) \times 0.131 \text{ L}}$$

$$= 54.3 \text{ g mol}^{-1}$$

The empirical formula mass is

$$\left(2 \text{ C atoms} \times \frac{12.0 \text{ u}}{1 \text{ C atom}}\right) + \left(3 \text{ H atoms} \times \frac{1.01 \text{ u}}{1 \text{ H atom}}\right) = 27.0 \text{ u}$$

The molar mass based on the empirical formula, 27.0 g mol^{-1}, is almost exactly one-half the observed molar mass of 54.3 g mol^{-1}. The molecular formula of the hydrocarbon is

$$C_{2\times2}H_{2\times3} = C_4H_6$$

The four-carbon alkane is butane, C_4H_{10}. Removal of 4 H atoms to obtain the formula C_4H_6 is achieved by inserting two C-to-C double bonds.

$$H_2C{=}CH{-}CH{=}CH_2 \quad \text{or} \quad H_2C{=}C{=}CH{-}CH_3$$

Two other possibilities involve the presence of a C-to-C triple bond.

$$H_3C{-}C{\equiv}C{-}CH_3 \quad \text{or} \quad H_3C{-}CH_2{-}C{\equiv}CH$$

Assess

The combination of combustion data and gas-law data yields a molecular formula with certainty. However, because of isomerism the exact structural formula cannot be pinpointed. All that we can say is that the hydrocarbon might have any one of the four structures shown, but it might be still another structure, for example, based on a ring of C atoms rather than a straight chain.

PRACTICE EXAMPLE A: When a 0.5120 g sample of a gaseous hydrocarbon was burned in excess oxygen, 1.687 g CO_2 and 0.4605 g H_2O were obtained. The density of the compound, in its vapor form, is 1.637 g/L at 25 °C and 101.3 kPa. Determine the molecular formula of the hydrocarbon, and draw a plausible structural formula for the molecule.

PRACTICE EXAMPLE B: An organic compound contains only C, H, N, and O. When the compound is burned in oxygen, with appropriate catalysts, nitrogen gas (N_2), carbon dioxide (CO_2), and water vapor (H_2O) are produced. A 0.1023 g sample of the compound yielded 151.2 mg CO_2, 69.62 mg H_2O, and 9.62 mL of $N_2(g)$ at 0.00 °C and 1.00 atm. The density of the compound, in its vapor form, was found to be 3.57 g L^{-1} at 127 °C and 748 mmHg. What is the molecular formula of the compound?

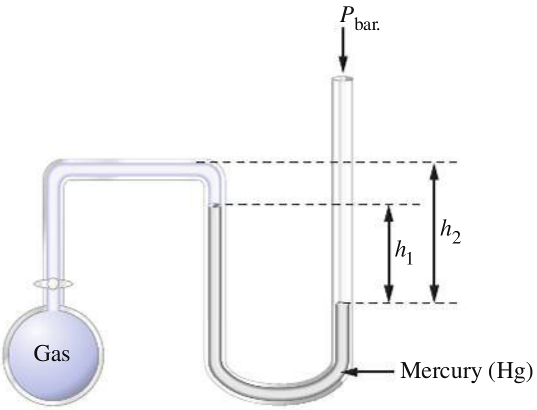
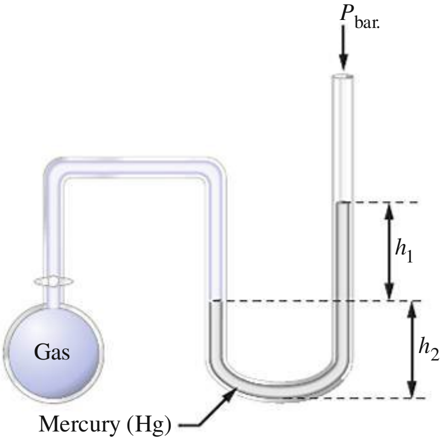
Exercises

Pressure and Its Measurement

1. Convert each pressure to an equivalent pressure in atmospheres. **(a)** 736 mmHg; **(b)** 0.776 bar; **(c)** 892 Torr; **(d)** 225 kPa.
2. Calculate the height of a mercury column required to produce a pressure **(a)** of 0.984 atm; **(b)** of 928 Torr; **(c)** equal to that of a column of water 142 ft high.
3. Calculate the height of a column of liquid benzene ($d = 0.879\ g/cm^3$), in meters, required to exert a pressure of 0.970 atm.
4. Calculate the height of a column of liquid glycerol ($d = 1.26\ g/cm^3$), in meters, required to exert the same pressure as 3.02 m of $CCl_4(l)$ ($d = 1.59\ g/cm^3$).
5. What is the pressure (in mmHg) of the gas inside the apparatus below if $P_{bar.} = 740$ mmHg, $h_1 = 30$ mm and $h_2 = 50$ mm?



6. What is the pressure (in mmHg) of the gas inside the apparatus below if $P_{bar.} = 740$ mmHg, $h_1 = 30$ mm and $h_2 = 40$ mm?



7. At times, a pressure is stated in units of *mass* per unit area rather than *force* per unit area. Express $P = 1$ atm in the unit kg/cm^2.
   [*Hint:* How is a mass in kilograms related to a force?]
8. Express $P = 1$ atm in pounds per square inch (psi).
   [*Hint:* Refer to Exercise 7.]

The Simple Gas Laws

9. A sample of $O_2(g)$ has a volume of 26.7 L at 762 Torr. What is the new volume if, with the temperature and amount of gas held constant, the pressure is **(a)** lowered to 385 Torr; **(b)** increased to 3.68 atm?
10. An 886 mL sample of Ne(g) is at 752 mmHg and 26 °C. What will be the new volume if, with the pressure and amount of gas held constant, the temperature is **(a)** increased to 98 °C; **(b)** lowered to −20 °C?
11. If 3.0 L of oxygen gas at 177 °C is cooled at constant pressure until the volume becomes 1.50 L, then what is the final temperature?
12. We want to change the volume of a fixed amount of gas from 725 mL to 2.25 L while holding the temperature constant. To what value must we change the pressure if the initial pressure is 105 kPa?
13. A 35.8 L cylinder of Ar(g) is connected to an evacuated 1875 L tank. If the temperature is held constant and the final pressure is 721 mmHg, what must have been the original gas pressure in the cylinder, in atmospheres?
14. A sample of $N_2(g)$ occupies a volume of 42.0 mL under the existing barometric pressure. Increasing the pressure by 85 mmHg reduces the volume to 37.7 mL. What is the prevailing barometric pressure, in millimeters of mercury?
15. A weather balloon filled with He gas has a volume of $2.00 \times 10^3\ m^3$ at ground level, where the atmospheric pressure is 1.000 atm and the temperature 27 °C. After the balloon rises high above Earth to a point where the atmospheric pressure is 0.340 atm, its volume increases to $5.00 \times 10^3\ m^3$. What is the temperature of the atmosphere at this altitude?
16. The photographs show the contraction of an argon-filled balloon when it is cooled by liquid nitrogen. To what approximate fraction of its original volume will the balloon shrink when it is cooled from a room temperature of 22 °C to a final temperature of about −22 °C?

17. What is the mass of argon gas in a 75.0 mL volume at STP?
18. What volume of gaseous chlorine at STP would you need to obtain a 250.0 g sample of gas?
19. A 27.6 mL sample of $PH_3(g)$ (used in the manufacture of flame-retardant chemicals) is obtained at STP.
    (a) What is the mass of this gas, in milligrams?
    (b) How many molecules of PH_3 are present?
20. A 5.0×10^{17} atom sample of radon gas is obtained.
    (a) What is the mass of this sample, in micrograms?
    (b) What is the volume of this sample at STP, in microliters?
21. You purchase a bag of potato chips at an ocean beach to take on a picnic in the mountains. At the picnic, you notice that the bag has become inflated, almost to the point of bursting. Use your knowledge of gas behavior to explain this phenomenon.
22. Scuba divers know that they must not ascend quickly from deep underwater because of a condition known as the *bends*, discussed in Chapter 13. Another concern is that they must constantly exhale during their ascent to prevent damage to the lungs and blood vessels. Describe what would happen to the lungs of a diver who inhaled compressed air at a depth of 30 m and held her breath while rising to the surface.

General Gas Equation

23. A sample of gas has a volume of 4.25 L at 25.6 °C and 748 mmHg. What will be the volume of this gas at 26.8 °C and 742 mmHg?
24. A 10.0 g sample of a gas has a volume of 5.25 L at 25 °C and 762 mmHg. If 2.5 g of the same gas is added to this *constant* 5.25 L volume and the temperature raised to 62 °C, what is the new gas pressure?
25. A constant-volume vessel contains 12.5 g of a gas at 21 °C. If the pressure of the gas is to remain constant as the temperature is raised to 210 °C, how many grams of gas must be released?
26. A 34.0 L cylinder contains 305 g $O_2(g)$ at 22 °C. How many grams of $O_2(g)$ must be released to reduce the pressure in the cylinder to 1.15 atm if the temperature remains constant?

Ideal Gas Equation

27. What is the volume, in milliliters, occupied by 89.2 g $CO_2(g)$ at 37 °C and 737 mmHg?
28. A 12.8 L cylinder contains 35.8 g O_2 at 46 °C. What is the pressure of this gas, in atmospheres?
29. Kr(g) in a 18.5 L cylinder exerts a pressure of 11.2 atm at 28.2 °C. How many grams of gas are present?
30. A 72.8 L constant-volume cylinder containing 7.41 g He is heated until the pressure reaches 3.50 atm. What is the final temperature in degrees Celsius?
31. A laboratory high vacuum system is capable of evacuating a vessel to the point that the amount of gas remaining is 5.0×10^9 molecules per cubic meter. What is the residual pressure in pascals?
32. What is the pressure, in pascals, exerted by 1242 g CO(g) when confined at −25 °C to a cylindrical tank 25.0 cm in diameter and 1.75 m high?

33. What is the molar volume of an ideal gas at **(a)** 25 °C and 1.00 atm; **(b)** 100 °C and 748 Torr?

34. At what temperature is the molar volume of an ideal gas equal to 22.4 L, if the pressure of the gas is 2.5 atm?

Determining Molar Mass

35. A 0.418 g sample of gas has a volume of 115 mL at 66.3 °C and 743 mmHg. What is the molar mass of this gas?

36. What is the molar mass of a gas found to have a density of 0.841 g/L at 415 K and 725 Torr?

37. What is the molecular formula of a gaseous fluoride of sulfur containing 70.4% F and having a density of approximately 4.5 g/L at 20 °C and 1 atm?

38. A 2.650 g sample of a gaseous compound occupies 428 mL at 24.3 °C and 742 mmHg. The compound consists of 15.5% C, 23.0% Cl, and 61.5% F, by mass. What is its molecular formula?

39. A gaseous hydrocarbon weighing 0.231 g occupies a volume of 102 mL at 23 °C and 749 mmHg. What is the molar mass of this compound? What conclusion can you draw about its molecular formula?

40. A 132.10 mL glass vessel weighs 56.1035 g when evacuated and 56.2445 g when filled with the gaseous hydrocarbon acetylene at 749.3 mmHg and 20.02 °C. What is the molar mass of acetylene? What conclusion can you draw about its molecular formula?

Gas Densities

41. A particular application calls for $N_2(g)$ with a density of 1.80 g/L at 32 °C. What must be the pressure of the $N_2(g)$ in millimeters of mercury? What is the molar volume under these conditions?

42. Monochloroethylene is used to make polyvinylchloride (PVC). It has a density of 2.56 g/L at 22.8 °C and 756 mmHg. What is the molar mass of monochloroethylene? What is the molar volume under these conditions?

43. In order for a gas-filled balloon to rise in air, the density of the gas in the balloon must be less than that of air.
(a) Consider air to have a molar mass of 28.96 g/mol; determine the density of air at 25 °C and 1 atm, in g/L.
(b) Show by calculation that a balloon filled with carbon dioxide at 25 °C and 1 atm could not be expected to rise in air at 25 °C.

44. Refer to Exercise 43, and determine the minimum temperature to which the balloon described in part **(b)** would have to be heated before it could begin to rise in air. (Ignore the mass of the balloon itself.)

45. The density of phosphorus vapor is 2.64 g/L at 310 °C and 775 mmHg. What is the molecular formula of the phosphorus under these conditions?

46. A particular gaseous hydrocarbon that is 82.7% C and 17.3% H by mass has a density of 2.33 g/L at 23 °C and 746 mmHg. What is the molecular formula of this hydrocarbon?

Gases in Chemical Reactions

47. What volume of $O_2(g)$ is consumed in the combustion of 75.6 L $C_3H_8(g)$ if both gases are measured at STP?

48. How many liters of $H_2(g)$ at STP are produced per gram of Al(s) consumed in the following reaction?

$$2\,\mathrm{Al(s)} + 6\,\mathrm{HCl(aq)} \longrightarrow 2\,\mathrm{AlCl_3(aq)} + 3\,\mathrm{H_2(g)}$$

49. A particular coal sample contains 3.28% S by mass. When the coal is burned, the sulfur is converted to $SO_2(g)$. What volume of $SO_2(g)$, measured at 23 °C and 738 mmHg, is produced by burning 1.2×10^6 kg of this coal?

50. One method of removing $CO_2(g)$ from a spacecraft is to allow the CO_2 to react with LiOH. How many liters of $CO_2(g)$ at 25.9 °C and 751 Torr can be removed per kilogram of LiOH consumed?

$$2\,\mathrm{LiOH(s)} + \mathrm{CO_2(g)} \longrightarrow \mathrm{Li_2CO_3(s)} + \mathrm{H_2O(l)}$$

51. A 3.57 g sample of a KCl–$KClO_3$ mixture is decomposed by heating and produces 119 mL $O_2(g)$, measured at 22.4 °C and 738 mmHg. What is the mass percent of $KClO_3$ in the mixture?

$$2\,\mathrm{KClO_3(s)} \longrightarrow 2\,\mathrm{KCl(s)} + 3\,\mathrm{O_2(g)}$$

52. Hydrogen peroxide, H_2O_2, is used to disinfect contact lenses. How many milliliters of $O_2(g)$ at 22 °C and 752 mmHg can be liberated from 10.0 mL of an aqueous solution containing 3.00% H_2O_2 by mass? The density of the aqueous solution of H_2O_2 is 1.01 g/mL.

$$2\,\mathrm{H_2O_2(aq)} \longrightarrow 2\,\mathrm{H_2O(l)} + \mathrm{O_2(g)}$$

53. Calculate the volume of $H_2(g)$, measured at 26 °C and 751 Torr, required to react with 28.5 L CO(g), measured at 0 °C and 760 Torr, in this reaction.

$$3\,\mathrm{CO(g)} + 7\,\mathrm{H_2(g)} \longrightarrow \mathrm{C_3H_8(g)} + 3\,\mathrm{H_2O(l)}$$

54. The Haber process is the principal method for fixing nitrogen (converting N_2 to nitrogen compounds).

$$\mathrm{N_2(g)} + 3\,\mathrm{H_2(g)} \longrightarrow 2\,\mathrm{NH_3(g)}$$

Assume that the reactant gases are completely converted to $NH_3(g)$ and that the gases behave ideally.
(a) What volume of $NH_3(g)$ can be produced from 152 L $N_2(g)$ and 313 L of $H_2(g)$ if the gases are measured at 315 °C and 5.25 atm?
(b) What volume of $NH_3(g)$, measured at 25 °C and 727 mmHg, can be produced from 152 L $N_2(g)$ and 313 L $H_2(g)$, measured at 315°C and 5.25 atm?

Mixtures of Gases

55. What is the volume, in liters, occupied by a mixture of 15.2 g Ne(g) and 34.8 g Ar(g) at 7.15 atm pressure and 26.7 °C?

56. A balloon filled with $H_2(g)$ at 0.0 °C and 1.00 atm has a volume of 2.24 L. What is the final gas volume if 0.10 mol He(g) is added to the balloon and the temperature is then raised to 100 °C while the pressure and amount of gas are held constant?

57. A gas cylinder of 53.7 L volume contains $N_2(g)$ at a pressure of 28.2 atm and 26 °C. How many grams of Ne(g) must we add to this same cylinder to raise the total pressure to 75.0 atm?

58. A 2.35 L container of $H_2(g)$ at 762 mmHg and 24 °C is connected to a 3.17 L container of He(g) at 728 mmHg and 24 °C. After mixing, what is the total gas pressure, in millimeters of mercury, with the temperature remaining at 24 °C?

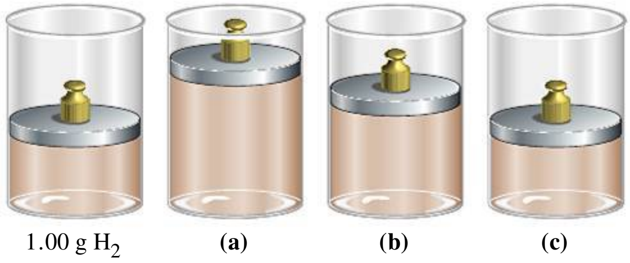
59. Which actions would you take to establish a pressure of 2.00 atm in a 2.24 L cylinder containing 1.60 g $O_2(g)$ at 0 °C? **(a)** add 1.60 g O_2; **(b)** release 0.80 g O_2; **(c)** add 2.00 g He; **(d)** add 0.60 g He.

60. A mixture of 4.0 g $H_2(g)$ and 10.0 g He(g) in a 4.3 L flask is maintained at 0 °C.
(a) What is the total pressure in the container?
(b) What is the partial pressure of each gas?

61. A 2.00 L container is filled with Ar(g) at 752 mmHg and 35 °C. A 0.728 g sample of C_6H_6 vapor is then added.
(a) What is the total pressure in the container?
(b) What is the partial pressure of Ar and of C_6H_6?

62. The chemical composition of air that is exhaled (expired) is different from ordinary air. A typical analysis of expired air at 37 °C and 1.00 atm, expressed as percent by volume, is 74.2% N_2, 15.2% O_2, 3.8% CO_2, 5.9% H_2O, and 0.9% Ar. The composition of ordinary air is given in Practice Example 6-12B.
(a) What is the ratio of the partial pressure of $CO_2(g)$ in expired air to that in ordinary air?
(b) Would you expect the density of expired air to be greater or less than that of ordinary air at the same temperature and pressure? Explain.
(c) Confirm your expectation by calculating the densities of ordinary air and expired air at 37 °C and 1.00 atm.

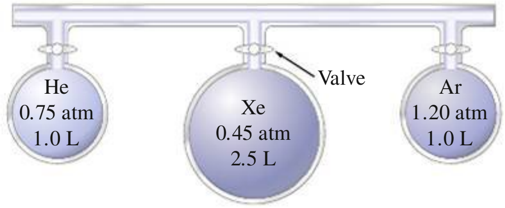
63. In the drawing below, 1.00 g $H_2(g)$ is maintained at 1 atm pressure in a cylinder closed off by a freely moving piston. Which sketch, (a), (b), or (c), best represents the mixture obtained when 1.00 g He(g) is added? Explain.



64. In the drawing above, 1.00 g $H_2(g)$ at 300 K is maintained at 1 atm pressure in a cylinder closed off by a freely moving piston. Which sketch, **(a)**, **(b)**, or **(c)**, best represents the mixture obtained when 0.50 g $H_2(g)$ is added and the temperature is reduced to 275 K? Explain your answer.

65. A 4.0 L sample of O_2 gas has a pressure of 1.0 atm. A 2.0 L sample of N_2 gas has a pressure of 2.0 atm. If these two samples are mixed and then compressed in a 2.0 L vessel, what is the final pressure of the mixture? Assume that the temperature remains unchanged.

66. The following figure shows the contents and pressures of three vessels of gas that are joined by a connecting tube.



After the valves on the vessels are opened, the final pressure is measured and found to be 0.675 atm. What is the total volume of the connecting tube? Assume that the temperature remains constant.

Collecting Gases over Liquids

67. A 1.65 g sample of Al reacts with excess HCl, and the liberated H_2 is collected over water at 25 °C at a barometric pressure of 744 mmHg. What volume of gaseous mixture, in liters, is collected?

$$2\,Al(s) + 6\,HCl(aq) \longrightarrow 2\,AlCl_3(aq) + 3\,H_2(g)$$

68. An 89.3 mL sample of wet $O_2(g)$ is collected over water at 21.3 °C at a barometric pressure of 756 mmHg (vapor pressure of water at 21.3 °C = 19 mmHg). **(a)** What is the partial pressure of $O_2(g)$ in the sample collected, in millimeters of mercury? **(b)** What is the volume percent O_2 in the gas collected? **(c)** How many grams of O_2 are present in the sample?

69. A sample of $O_2(g)$ is collected over water at 24 °C. The volume of gas is 1.16 L. In a subsequent experiment, it is determined that the mass of O_2 present is 1.46 g. What must have been the barometric pressure at the time the gas was collected? (Vapor pressure of water = 22.4 Torr.)

70. A 1.072 g sample of He(g) is found to occupy a volume of 8.446 L when collected over hexane at 25.0 °C and 738.6 mmHg barometric pressure. Use these data to determine the vapor pressure of hexane at 25 °C.

71. At elevated temperatures, solid sodium chlorate ($NaClO_3$) decomposes to produce sodium chloride, NaCl, and O_2 gas. A 0.8765 g sample of impure sodium chlorate was heated until the production of oxygen ceased. The oxygen gas was collected over water and occupied a volume of 57.2 mL at 23.0 °C and 734 Torr. Calculate the mass percentage of $NaClO_3$ in the original sample. Assume that none of the impurities produce oxygen on heating. The vapor pressure of water is 21.07 Torr at 23 °C.

72. When solid $KClO_3$ is heated strongly, it decomposes to form solid potassium chloride, KCl, and O_2 gas. A 0.415 g sample of impure $KClO_3$ is heated strongly and the O_2 gas produced by the decomposition is collected over water. When the wet O_2 gas is cooled back to 26 °C, the total volume is 229 mL and the total pressure is 323 Torr. What is the mass percentage of $KClO_3$ in the original sample? Assume that none of the impurities produce oxygen on heating. The vapor pressure of water is 25.22 Torr at 26 °C.

Kinetic-Molecular Theory

73. Calculate u_{rms}, in meters per second, for $Cl_2(g)$ molecules at 30 °C.

74. The u_{rms} of H_2 molecules at 273 K is 1.84×10^3 m/s. At what temperature is u_{rms} for H_2 twice this value?

75. Refer to Example 6-14. What must be the molecular mass of a gas if its molecules are to have a root-mean-square speed at 25 °C equal to the speed of the M-16 rifle bullet?

76. Refer to Example 6-14. Noble gases (group 18) exist as atoms, not molecules (they are monatomic). Cite one noble gas whose u_{rms} at 25 °C is higher than the speed of the rifle bullet and one whose u_{rms} is lower.

77. At what temperature will u_{rms} for Ne(g) be the same as u_{rms} for He at 300 K?

78. Determine u_m, $\overline{u}$, and u_{rms} for a group of ten automobiles clocked by radar at speeds of 38, 44, 45, 48, 50, 55, 55, 57, 58, and 60 mi/h, respectively.

79. Calculate the average kinetic energy, $\overline{e_k}$, for $O_2(g)$ at 298 K and 1.00 atm.

80. Calculate the total kinetic energy, in joules, of 155 g $N_2(g)$ at 25 °C and 1.00 atm. [*Hint*: First calculate the average kinetic energy, $\overline{e_k}$.]

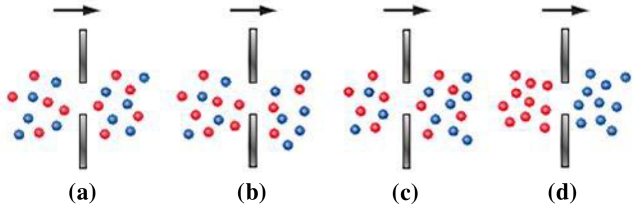
Diffusion and Effusion of Gases

81. If 0.00484 mol $N_2O(g)$ effuses through an orifice in a certain period of time, how much $NO_2(g)$ would effuse in the same time under the same conditions?

82. A sample of $N_2(g)$ effuses through a tiny hole in 38 s. What must be the molar mass of a gas that requires 64 s to effuse under identical conditions?

83. What are the ratios of the diffusion rates for the pairs of gases **(a)** N_2 and O_2; **(b)** H_2O and D_2O (D = deuterium, i.e., ^2_1H); **(c)** $^{14}CO_2$ and $^{12}CO_2$; **(d)** $^{235}UF_6$ and $^{238}UF_6$?

84. Which of the following visualizations best represents the distribution of O_2 and SO_2 molecules near an orifice some time after effusion occurs in the direction indicated by the arrows? The initial condition was one of equal numbers of O_2 molecules (●) and SO_2 molecules (●) on the left side of the orifice. Explain.



(a) (b) (c) (d)

85. It takes 22 hours for a neon-filled balloon to shrink to half its original volume at STP. If the same balloon had been filled with helium, then how long would it have taken for the balloon to shrink to half its original volume at STP?

86. The molar mass of radon gas was first estimated by comparing its diffusion rate with that of mercury vapor, Hg(g). What is the molar mass of radon if mercury vapor diffuses 1.082 times as fast as radon gas? Assume that Graham's law holds for diffusion.

Nonideal Gases

87. Refer to Example 6-17. Recalculate the pressure of $Cl_2(g)$ by using both the ideal gas equation and the van der Waals equation at the temperatures **(a)** 100 °C; **(b)** 200 °C; **(c)** 400 °C. From the results, confirm the statement that a gas tends to be more ideal at high temperatures than at low temperatures.

88. Use both the ideal gas equation and the van der Waals equation to calculate the pressure exerted by 1.50 mol of $SO_2(g)$ when it is confined at 298 K to a volume of **(a)** 100.0 L, **(b)** 50.0 L, **(c)** 20.0 L, **(d)** 10.0 L. Under which of these conditions is the pressure calculated with the ideal gas equation within a few percent of that calculated with the van der Waals equation? Use values of *a* and *b* from Table 6.5.

89. Use the value of the van der Waals constant *b* for He(g), given in Table 6.5, to estimate the radius, *r*, of a single helium atom. Give your answer in picometers. [*Hint*: The volume of a sphere of radius *r* is $4\pi r^3/3$.]

90. **(a)** Use the value of the van der Waals constant *b* for $CH_4(g)$, given in Table 6.5, to estimate the radius of the CH_4 molecule. (See Exercise 89.) How does your estimate of the radius compare with the value $r = 228$ pm, obtained experimentally from an analysis of the structure of solid methane? **(b)** The density of $CH_4(g)$ is 66.02 g mL^{-1} at 100 bar and 325 K. What is the value of compressibility factor at this temperature and pressure?

Integrative and Advanced Exercises

91. Explain why it is necessary to include the density of Hg(l) and the value of the acceleration due to gravity, *g*, in a precise definition of a millimeter of mercury (page 194).

92. Assume the following initial conditions for the graphs labeled A, B, and C in Figure 6-7. (A) 10.0 mL at 400 K; (B) 20.0 mL at 400 K; (C) 40.0 mL at 400 K. Use Charles's law to calculate the volume of each gas at 0, −100, −200, −250, and −270 °C. Show that the volume of each gas becomes zero at −273.15 °C.

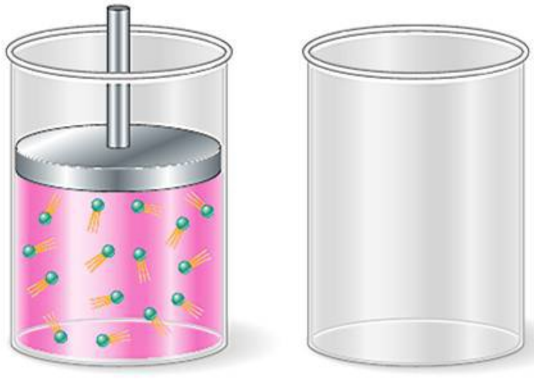
93. Consider the diagram below. The "initial" sketch illustrates, both at the macroscopic and molecular levels, an initial condition: 1 mol of a gas at 273 K and 1.00 atm. With as much detail as possible, illustrate the final condition after each of the following changes.

(a) The pressure is changed to 250 mmHg while standard temperature is maintained.

(b) The temperature is changed to 140 K while standard pressure is maintained.

(c) The pressure is changed to 0.5 atm while the temperature is changed to 550 K.

(d) An additional 0.5 mol of gas is introduced into the cylinder, the temperature is changed to 135 °C, and the pressure is changed to 2.25 atm.



94. Two evacuated bulbs of equal volume are connected by a tube of negligible volume. One of the bulbs is placed in a constant-temperature bath at 225 K and the other bulb is placed in a constant-temperature bath at 350 K. Exactly 1 mol of an ideal gas is injected into the system. Calculate the final number of moles of gas in each bulb.

95. A compound is 85.6% carbon by mass. The rest is hydrogen. When 10.0 g of the compound is evaporated at 50.0 °C, the vapor occupies 6.30 L at 1.00 atm pressure. What is the molecular formula of the compound?

96. A 0.7178 g sample of a hydrocarbon occupies a volume of 390.7 mL at 65.0 °C and 99.2 kPa. When the sample is burned in excess oxygen, 2.4267 g CO_2 and 0.4967 g H_2O are obtained. What is the molecular formula of the hydrocarbon? Write a plausible structural formula for the molecule.

97. A 3.05 g sample of $NH_4NO_3(s)$ is introduced into an evacuated 2.18 L flask and then heated to 250 °C. What is the total gas pressure, in atmospheres, in the flask at 250 °C when the NH_4NO_3 has completely decomposed?

$$NH_4NO_3(s) \longrightarrow N_2O(g) + 2\,H_2O(g)$$

98. Ammonium nitrite, NH_4NO_2, decomposes according to the chemical equation below.

$$NH_4NO_2(s) \longrightarrow N_2(g) + 2\,H_2O(g)$$

What is the total volume of products obtained when 128 g NH_4NO_2 decomposes at 819 °C and 101 kPa?

99. A mixture of 1.00 g H_2 and 8.60 g O_2 is introduced into a 1.500 L flask at 25 °C. When the mixture is ignited, an explosive reaction occurs in which water is the only product. What is the total gas pressure when the flask is returned to 25 °C? (The vapor pressure of water at 25 °C is 23.8 mmHg.)

100. In the reaction of $CO_2(g)$ and solid sodium peroxide (Na_2O_2), solid sodium carbonate (Na_2CO_3) and oxygen gas are formed. This reaction is used in submarines and space vehicles to remove expired $CO_2(g)$ and to generate some of the $O_2(g)$ required for breathing. Assume that the volume of gases exchanged in the lungs equals 4.0 L/min, the CO_2 content of expired air is 3.8% CO_2 by volume, and the gases are at 25 °C and 735 mmHg. If the $CO_2(g)$ and $O_2(g)$ in the above reaction are measured at the same temperature and pressure, **(a)** how many milliliters of $O_2(g)$ are produced per minute and **(b)** at what rate is the $Na_2O_2(s)$ consumed, in grams per hour?

101. What is the partial pressure of $Cl_2(g)$, in millimeters of mercury, at 0.00 °C and 1.00 atm in a gaseous mixture that consists of 46.5% N_2, 12.7% Ne, and 40.8% Cl_2, by mass?

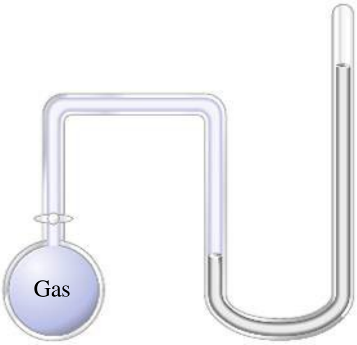
102. A gaseous mixture of He and O_2 has a density of 0.518 g/L at 25 °C and 721 mmHg. What is the mass percent He in the mixture?

103. When working with a mixture of gases, it is sometimes convenient to use an *apparent molar mass* (a weighted-average molar mass). Think in terms of replacing the mixture with a hypothetical single gas. What is the apparent molar mass of air, given that air is 78.08% N_2, 20.95% O_2, 0.93% Ar, and 0.036% CO_2, by volume?

104. A mixture of $N_2O(g)$ and $O_2(g)$ can be used as an anesthetic. In a particular mixture, the partial pressures of N_2O and O_2 are 612 Torr and 154 Torr, respectively. Calculate **(a)** the mass percentage of N_2O in this mixture, and **(b)** the apparent molar mass of this anesthetic. [*Hint*: For part (b), refer to Exercise 103.]

105. Gas cylinder A has a volume of 48.2 L and contains $N_2(g)$ at 8.35 atm at 25 °C. Gas cylinder B, of unknown volume, contains He(g) at 9.50 atm and 25 °C. When the two cylinders are connected and the gases mixed, the pressure in each cylinder becomes 8.71 atm. What is the volume of cylinder B?

106. The accompanying sketch is that of a closed-end manometer. Describe how the gas pressure is measured. Why is a measurement of $P_{\text{bar.}}$ not necessary when using this manometer? Explain why the closed-end manometer is more suitable for measuring low pressures and the open-end manometer more suitable for measuring pressures nearer atmospheric pressure.



107. Producer gas is a type of fuel gas made by passing air or steam through a bed of hot coal or coke. A typical producer gas has the following composition in percent by volume: 8.0% CO_2, 23.2% CO, 17.7% H_2, 1.1% CH_4, and 50.0% N_2.
(a) What is the density of this gas at 23 °C and 763 mmHg, in grams per liter?
(b) What is the partial pressure of CO in this mixture at 0.00 °C and 1 atm?
(c) What volume of air, measured at 23 °C and 741 Torr, is required for the complete combustion of 1.00×10^3 L of this producer gas, also measured at 23 °C and 741 Torr?
[*Hint:* Which three of the constituent gases are combustible?]

108. The heat required to sustain animals while they hibernate comes from the biochemical combustion of fatty acids, such as arachidonic acid, $C_{20}H_{32}O_2$. What volume of air, measured at 298 K and 1.00 atm, is required to burn 2.00 kg $C_{20}H_{32}O_2$? Air is approximately 78.1% N_2 and 20.9% O_2, by volume. Other gases make up the remaining 1.0%.

109. A mixture of $H_2(g)$ and $O_2(g)$ is prepared by electrolyzing 1.32 g water, and the mixture of gases is collected over water at 30 °C and 748 mmHg. The volume of "wet" gas obtained is 2.90 L. What must be the vapor pressure of water at 30 °C?

$$2\,H_2O(l) \xrightarrow{\text{electrolysis}} 2\,H_2(g) + O_2(g)$$

110. Aluminum (Al) and iron (Fe) each react with hydrochloric acid solution (HCl) to produce a chloride salt and hydrogen gas, $H_2(g)$. A 0.1924 g sample of a mixture of Al and Fe is treated with excess HCl solution. A volume of 159 mL of H_2 gas is collected over water at 19.0 °C and 841 Torr. What is the percent (by mass) of Fe in the mixture? The vapor pressure of water at 19.0 °C is 16.5 Torr.

111. A 0.168 L sample of $O_2(g)$ is collected over water at 26 °C and a barometric pressure of 737 mmHg. In the gas that is collected, what is the percent water vapor **(a)** by volume; **(b)** by number of molecules; **(c)** by mass? (Vapor pressure of water at 26 °C = 25.2 mmHg.)

112. A breathing mixture is prepared in which He is substituted for N_2. The gas is 79% He and 21% O_2, by volume. **(a)** What is the density of this mixture in grams per liter at 25 °C and 1.00 atm? **(b)** At what pressure would the He–O_2 mixture have the same density as that of air at 25 °C and 1.00 atm? See Exercise 103 for the composition of air.

113. Chlorine dioxide, ClO_2, is sometimes used as a chlorinating agent for water treatment. It can be prepared from the reaction below:

$$Cl_2(g) + 4\,NaClO(aq) \longrightarrow 4\,NaCl(aq) + 2\,ClO_2(g)$$

In an experiment, 1.0 L $Cl_2(g)$, measured at 10.0 °C and 4.66 atm, is dissolved in 0.750 L of 2.00 M NaClO(aq). If 25.9 g of pure ClO_2 is obtained, then what is the percent yield for this experiment?

114. The amount of ozone, O_3, in a mixture of gases can be determined by passing the mixture through a solution of excess potassium iodide, KI. Ozone reacts with the iodide ion as follows:

$$O_3(g) + 3I^-(aq) + H_2O(l) \longrightarrow O_2(g) + I_3^-(aq) + 2OH^-(aq)$$

The amount of I_3^- produced is determined by titrating with thiosulfate ion, $S_2O_3^{2-}$:

$$I_3^-(aq) + 2\,S_2O_3^{2-}(aq) \longrightarrow 3I^-(aq) + S_4O_6^{2-}(aq)$$

A mixture of gases occupies a volume of 53.2 L at 18 °C and 0.993 atm. The mixture is passed slowly through a solution containing an excess of KI to ensure that all the ozone reacts. The resulting solution requires 26.2 mL of 0.1359 M $Na_2S_2O_3$ to titrate to the end point. Calculate the mole fraction of ozone in the original mixture.

115. A 0.1052 g sample of $H_2O(l)$ in an 8.050 L sample of dry air at 30.1 °C evaporates completely. To what temperature must the air be cooled to give a relative humidity of 80.0%? Vapor pressures of water: 20 °C, 17.54 mmHg; 19 °C, 16.48 mmHg; 18 °C, 15.48 mmHg; 17 °C, 14.53 mmHg; 16 °C, 13.63 mmHg; 15 °C, 12.79 mmHg. [*Hint*: Go to Focus On feature for Chapter 6 on the MasteringChemistry site, www.masteringchemistry.com, for a discussion of relative humidity.]

116. An alternative to Figure 6-6 is to plot P against $1/V$. The resulting graph is a straight line passing through the origin. Use Boyle's data from Feature Problem 125 to draw such a straight-line graph. What factors would affect the *slope* of this straight line? Explain.

117. We have noted that atmospheric pressure depends on altitude. Atmospheric pressure as a function of altitude can be calculated with an equation known as the barometric formula:

$$P = P_0 \times 10^{-Mgh/2.303RT}$$

In this equation, P and P_0 can be in any pressure units, for example, Torr. P_0 is the pressure at sea level, generally taken to be 1.00 atm or its equivalent. The units in the exponential term must be SI units, however. Use the barometric formula to
(a) estimate the barometric pressure at the top of Mt. Whitney in California (altitude: 14,494 ft; assume a temperature of 10 °C)
(b) show that barometric pressure decreases by one-thirtieth in value for every 900-ft increase in altitude

118. Consider a sample of $O_2(g)$ at 298 K and 1.0 atm. Calculate **(a)** u_{rms} and **(b)** the fraction of molecules that have speed equal to u_{rms}.

119. A nitrogen molecule (N_2) having the average kinetic energy at 300 K is released from Earth's surface to travel upward. If the molecule could move upward without colliding with other molecules, then how high would it go before coming to rest? Give your answer in kilometers. [*Hint*: When the molecule comes to rest, the potential energy of the molecule will be mgh, where m is the molecular mass in kilograms, $g = 9.81\ \text{m s}^{-2}$ is the acceleration due to gravity, and h is the height, in meters, above Earth's surface.]

120. For $H_2(g)$ at 0 °C and 1 atm, calculate the percentage of molecules that have speed **(a)** $0\ \text{m s}^{-1}$; **(b)** $500\ \text{m s}^{-1}$; **(c)** $1000\ \text{m s}^{-1}$; **(d)** $1500\ \text{m s}^{-1}$; **(e)** $2000\ \text{m s}^{-1}$; **(f)** $2500\ \text{m s}^{-1}$; **(g)** $3500\ \text{m s}^{-1}$. Graph your results to obtain your own version of Figure 6-15.

121. If the van der Waals equation is solved for volume, a cubic equation is obtained.

(a) Derive the equation below by rearranging equation (6.26).

$$V^3 - n\left(\frac{RT + bP}{P}\right)V^2 + \left(\frac{n^2a}{P}\right)V - \frac{n^3ab}{P} = 0$$

(b) What is the volume, in liters, occupied by 185 g $CO_2(g)$ at a pressure of 12.5 atm and 286 K? For $CO_2(g)$, $a = 3.61\ \text{L}^2\ \text{atm mol}^{-2}$ and $b = 0.0429\ \text{L mol}^{-1}$. [*Hint*: Use the ideal gas equation to obtain an estimate of the volume. Then refine your estimate, either by trial and error, or using the method of successive approximations. See Appendix A, pages A5–A6, for a description of the method of successive approximations.]

122. According to the *CRC Handbook of Chemistry and Physics* (83rd ed.), the molar volume of $O_2(g)$ is $0.2168\ \text{L mol}^{-1}$ at 280 K and 10 MPa. (Note: 1 MPa = 1×10^6 Pa.)

(a) Use the van der Waals equation to calculate the pressure of one mole of $O_2(g)$ at 280 K if the volume is 0.2168 L. What is the % error in the calculated pressure? The van der Waals constants are $a = 1.382\ \text{L}^2\ \text{bar mol}^{-2}$ and $b = 0.0319\ \text{L mol}^{-1}$.

(b) Use the ideal gas equation to calculate the volume of one mole of $O_2(g)$ at 280 K and 10 MPa. What is the % error in the calculated volume?

123. A particular equation of state for $O_2(g)$ has the form

$$P\overline{V} = RT\left(1 + \frac{B}{\overline{V}} + \frac{C}{\overline{V}^2}\right)$$

where $\overline{V}$ is the molar volume, $B = -21.89\ \text{cm}^3/\text{mol}$ and $C = 1230\ \text{cm}^6/\text{mol}$.

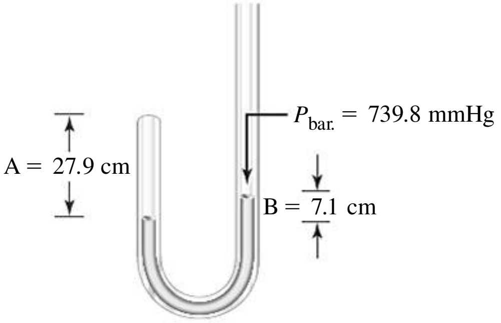
(a) Use the equation to calculate the pressure exerted by 1 mol $O_2(g)$ confined to a volume of 500 cm^3 at 273 K.

(b) Is the result calculated in part **(a)** consistent with that suggested for $O_2(g)$ by Figure 6-20? Explain.

124. A 0.156 g sample of a magnesium–aluminum alloy dissolves completely in an excess of HCl(aq). The liberated $H_2(g)$ is collected over water at 5 °C when the barometric pressure is 752 Torr. After the gas is collected, the water and gas gradually warm to the prevailing room temperature of 23 °C. The pressure of the collected gas is again equalized against the barometric pressure of 752 Torr, and its volume is found to be 202 mL. What is the percent composition of the magnesium–aluminum alloy? (Vapor pressure of water: 6.54 mmHg at 5 °C and 21.07 mmHg at 23 °C).

Feature Problems

125. Shown to the right is a diagram of Boyle's original apparatus. At the start of the experiment, the length of the air column (A) on the left was 30.5 cm and the heights of mercury in the arms of the tube were equal. When mercury was added to the right arm of the tube, a difference in mercury levels (B) was produced, and the entrapped air on the left was compressed into a shorter length of the tube (smaller volume) as shown in the illustration for A = 27.9 cm and B = 7.1 cm. Boyle's values of A and B, in centimeters, are listed as follows:

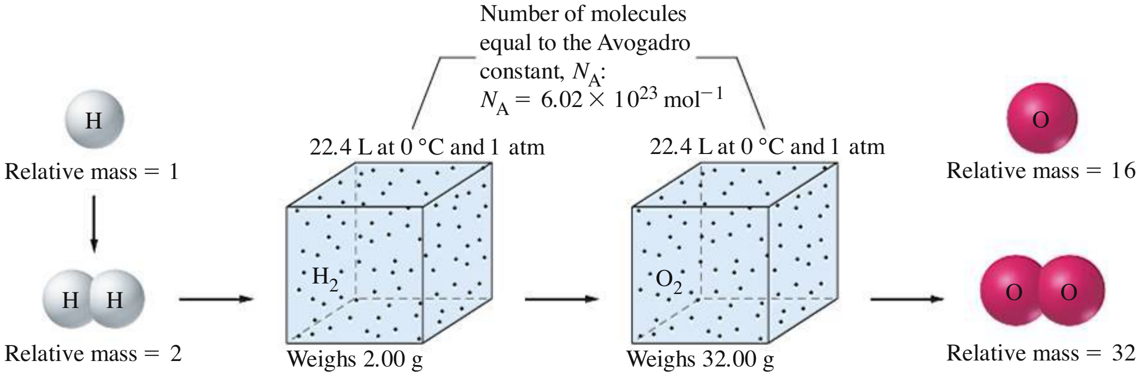


A:	30.5	27.9	25.4	22.9	20.3
B:	0.0	7.1	15.7	25.7	38.3
A:	17.8	15.2	12.7	10.2	7.6
B:	53.8	75.4	105.6	147.6	224.6

Barometric pressure at the time of the experiment was 739.8 mmHg. Assuming that the length of the air column (A) is proportional to the volume of air, show that these data conform reasonably well to Boyle's law.

126. In 1860, Stanislao Cannizzaro showed how Avogadro's hypothesis could be used to establish the atomic masses of elements in gaseous compounds. Cannizzaro took the atomic mass of hydrogen to be exactly one and assumed that hydrogen exists as H_2 molecules (molecular mass = 2). Next, he determined the volume of $H_2(g)$ at 0.00 °C and 1.00 atm that has a mass of exactly 2 g. This volume is 22.4 L. Then he assumed that 22.4 L of any other gas would have the same number of molecules as in 22.4 L of $H_2(g)$. (Here is where Avogadro's hypothesis entered in.) Finally, he reasoned that the ratio of the mass of 22.4 L of any other gas to the mass of 22.4 L of $H_2(g)$ should be the same as the ratio of their molecular masses. The sketch below illustrates Cannizzaro's reasoning in establishing the atomic weight of oxygen as 16. The gases in the table all contain the element X. Their molecular masses were determined by Cannizzaro's method. Use the percent composition data to deduce the atomic mass of X, the number of atoms of X in each of the gas molecules, and the identity of X.

Compound	Molecular Mass, *u*	Mass Percent X, %
Nitryl fluoride	65.01	49.4
Nitrosyl fluoride	49.01	32.7
Thionyl fluoride	86.07	18.6
Sulfuryl fluoride	102.07	31.4



127. In research that required the careful measurement of gas densities, John Rayleigh, a physicist, found that the density of $O_2(g)$ had the same value whether the gas was obtained from air or derived from one of its compounds. The situation with $N_2(g)$ was different, however. The density of $N_2(g)$ had the same value when the $N_2(g)$ was derived from any of various compounds, but a *different* value if the $N_2(g)$ was extracted from air. In 1894, Rayleigh enlisted the aid of William Ramsay, a chemist, to solve this apparent mystery; in the course of their work they discovered the noble gases.

(a) Why do you suppose that the $N_2(g)$ extracted from liquid air did *not* have the same density as $N_2(g)$ obtained from its compounds?

(b) Which gas do you suppose had the greater density: $N_2(g)$ extracted from air or $N_2(g)$ prepared from nitrogen compounds? Explain.

(c) The way in which Ramsay proved that nitrogen gas extracted from air was itself a mixture of gases involved allowing this nitrogen to react with magnesium metal to form magnesium nitride. Explain the significance of this experiment.

(d) Calculate the *percent difference* in the densities at 0.00 °C and 1.00 atm of Rayleigh's $N_2(g)$ extracted from air and $N_2(g)$ derived from nitrogen compounds. [The volume percentages of the major components of air are 78.084% N_2, 20.946% O_2, 0.934% Ar, and 0.0379% CO_2.]

128. The equation $d/P = M/RT$, which can be derived from equation (6.14), suggests that the ratio of the density (d) to pressure (P) of a gas at constant temperature should be a constant. The gas density data at the end of this question were obtained for $O_2(g)$ at various pressures at 273.15 K.

(a) Calculate values of d/P, and with a graph or by other means determine the ideal value of the term d/P for $O_2(g)$ at 273.15 K.
[*Hint:* The ideal value is that associated with a perfect (ideal) gas.]

(b) Use the value of d/P from part **(a)** to calculate a precise value for the atomic mass of oxygen, and compare this value with that listed on the inside front cover.

P, mmHg:	760.00	570.00	380.00	190.00
d, g/L:	1.428962	1.071485	0.714154	0.356985

129. A sounding balloon is a rubber bag filled with $H_2(g)$ and carrying a set of instruments (the payload). Because this combination of bag, gas, and payload has a smaller mass than a corresponding volume of air, the balloon rises. As the balloon rises, it expands. From the table below, estimate the maximum height to which a spherical balloon can rise given the mass of balloon, 1200 g; payload, 1700 g: quantity of $H_2(g)$ in balloon, 120 ft^3 at 0.00 °C and 1.00 atm; diameter of balloon at maximum height, 25 ft. Air pressure and temperature as functions of altitude are:

Altitude, km	Pressure, mb	Temperature, K
0	1.0×10^3	288
5	5.4×10^2	256
10	2.7×10^2	223
20	5.5×10^1	217
30	1.2×10^1	230
40	2.9×10^0	250
50	8.1×10^{-1}	250
60	2.3×10^{-1}	256

Self-Assessment Exercises

130. In your own words, define or explain each term or symbol. **(a)** atm; **(b)** STP; **(c)** *R*; **(d)** partial pressure; **(e)** u_{rms}.

131. Briefly describe each concept or process: **(a)** absolute zero of temperature; **(b)** collection of a gas over water; **(c)** effusion of a gas; **(d)** law of combining volumes.

132. Explain the important distinctions between **(a)** barometer and manometer; **(b)** Celsius and Kelvin temperature; **(c)** ideal gas equation and general gas equation; **(d)** ideal gas and real gas.

133. Which exerts the greatest pressure, **(a)** a 75.0 cm column of $Hg(l)$ $(d = 13.6 \text{ g/mL})$; **(b)** a column of air 10 mi high; **(c)** a 5.0 m column of $CCl_4(l)$ $(d = 1.59 \text{ g/mL})$; **(d)** 10.0 g $H_2(g)$ at STP?

134. For a fixed amount of gas at a fixed pressure, changing the temperature from 100.0 °C to 200 K causes the gas volume to **(a)** double; **(b)** increase, but not to twice its original value; **(c)** decrease; **(d)** stay the same.

135. A fragile glass vessel will break if the internal pressure equals or exceeds 2.0 bar. If the vessel is sealed at 0 °C and 1.0 bar, then at what temperature will the vessel break? Assume that the vessel does not expand when heated.

136. Which of the following choices represents the molar volume of an ideal gas at 25 °C and 1.5 atm? **(a)** $(298 \times 1.5/273) \times 22.4 \text{ L}$; **(b)** 22.4 L; **(c)** $(273 \times 1.5/298) \times 22.4 \text{ L}$; **(d)** $[298/(273 \times 1.5)] \times 22.4 \text{ L}$; **(e)** $[273/(298 \times 1.5)] \times 22.4 \text{ L}$.

137. The gas with the greatest density at STP is **(a)** N_2O; **(b)** Kr; **(c)** SO_3; **(d)** Cl_2.

138. If the Kelvin temperature of a sample of ideal gas doubles (e.g., from 200 K to 400 K), what happens to the root-mean-square speed, u_{rms}? **(a)** u_{rms} increases by a factor of $\sqrt{2}$; **(b)** u_{rms} increases by a factor of 2; **(c)** u_{rms} decreases by a factor of 2; **(d)** u_{rms} increases by a factor of 4; **(e)** u_{rms} decreases by a factor of 4.

139. Consider the statements (a) to (e) below. Assume that $H_2(g)$ and $O_2(g)$ behave ideally. State whether each of the following statements is true or false. For each false statement, explain how you would change it to make it a true statement.

(a) Under the same conditions of temperature and pressure, the average kinetic energy of O_2 molecules is less than that of H_2 molecules.

(b) Under the same conditions of temperature and pressure, H_2 molecules move faster, on average, than O_2 molecules.

(c) The volume of 1.00 mol of $H_2(g)$ at 25.0 °C, 1.00 atm is 22.4 L.

(d) The volume of 2.0 g $H_2(g)$ is equal to the volume of 32.0 g $O_2(g)$, at the same temperature and pressure.

(e) In a mixture of H_2 and O_2 gases, with partial pressures P_{H_2} and P_{O_2}, respectively, the total pressure is the larger of P_{H_2} and P_{O_2}.

140. A sample of $O_2(g)$ is collected over water at 23 °C and a barometric pressure of 751 Torr. The vapor pressure of water at 23 °C is 21 mmHg. The partial pressure of $O_2(g)$ in the sample collected is **(a)** 21 mmHg; **(b)** 751 Torr; **(c)** 0.96 atm; **(d)** 1.02 atm.

141. At 0 °C and 0.500 atm, 4.48 L of gaseous NH_3 **(a)** contains 6.02×10^{22} molecules; **(b)** has a mass of 17.0 g; **(c)** contains 0.200 mol NH_3; **(d)** has a mass of 3.40 g.

142. To establish a pressure of 2.00 atm in a 2.24 L cylinder containing 1.60 g $O_2(g)$ at 0 °C, **(a)** add 1.60 g O_2; **(b)** add 0.60 g $He(g)$; **(c)** add 2.00 g $He(g)$; **(d)** release 0.80 g $O_2(g)$.

143. Carbon monoxide, CO, and hydrogen react according to the equation below.

$$3\,CO(g) + 7\,H_2(g) \longrightarrow C_3H_8(g) + 3\,H_2O(g)$$

What volume of which reactant gas remains if 12.0 L $CO(g)$ and 25.0 L $H_2(g)$ are allowed to react? Assume that the volumes of both gases are measured at the same temperature and pressure.

144. A mixture of 5.0×10^{-5} mol $H_2(g)$ and 5.0×10^{-5} mol $SO_2(g)$ is placed in a 10.0 L container at 25 °C. The container has a pinhole leak. After a period of time, the partial pressure of $H_2(g)$ in the container **(a)** is less than that of the $SO_2(g)$; **(b)** is equal to that of the $SO_2(g)$; **(c)** exceeds that of the $SO_2(g)$; **(d)** is the same as in the original mixture.

145. Under which conditions is Cl_2 most likely to behave like an ideal gas? Explain. **(a)** 100 °C and 10.0 atm; **(b)** 0 °C and 0.50 atm; **(c)** 200 °C and 0.50 atm; **(d)** 400 °C and 10.0 atm.

146. Without referring to Table 6.5, state which species in each of the following pairs has the greater value for the van der Waals constant *a*, and which one has the greater value for the van der Waals constant *b*. **(a)** He or Ne; **(b)** CH_4 or C_3H_8; **(c)** H_2 or Cl_2.

147. Explain why the height of the mercury column in a barometer is independent of the diameter of the barometer tube.

148. A gaseous hydrocarbon that is 82.7% C and 17.3% H by mass has a density of 2.35 g/L at 25 °C and 752 Torr. What is the molecular formula of this hydrocarbon?

149. Draw a box to represent a sample of air containing N_2 molecules (represented as squares) and O_2 molecules (represented as circles) in their correct proportions. How many squares and circles would you need to draw to also represent the $CO_2(g)$ in air through a single mark? What else should you add to the box for this more complete representation of air? [*Hint:* See Exercise 103.]

150. Appendix E describes a useful study aid known as concept mapping. Using the method presented in Appendix E, construct a concept map illustrating the different concepts to show the relationships among all the gas laws described in this chapter.

7-9 Fuels as Sources of Energy

Potassium reacts with water, liberating sufficient heat to ignite the hydrogen evolved. The transfer of heat between substances in chemical reactions is an important aspect of thermochemistry.

Natural gas consists mostly of methane, CH_4. As we learned in Chapter 4, the combustion of a hydrocarbon, such as methane, yields carbon dioxide and water as products. More important, however, is another "product" of this reaction, which we have not previously mentioned: heat. This heat can be used to produce hot water in a water heater, to heat a house, or to cook food.

Thermochemistry is the branch of chemistry concerned with the heat effects that accompany chemical reactions. To understand the relationship between heat and chemical and physical changes, we must start with some basic definitions. We will then explore the concept of heat and the methods used to measure the transfer of energy across boundaries. Another form of energy transfer is work, and, in combination with heat, we will define the first law of thermodynamics. At this point, we will establish the relationship between heats of reaction and changes in internal energy and enthalpy. We will see that the tabulation of the change in internal energy and change in enthalpy can be used to calculate, directly or indirectly, energy changes during chemical and physical changes. Finally, concepts introduced in this chapter will answer a host of practical questions, such as

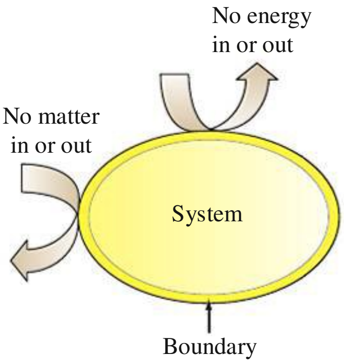
◀ Thermochemistry is a subfield of a larger discipline called *thermodynamics*. The broader aspects of thermodynamics are considered in Chapters 19 and 20.

why natural gas is a better fuel than coal and why the energy value of fats is greater than that of carbohydrates and proteins.

7-1 Getting Started: Some Terminology

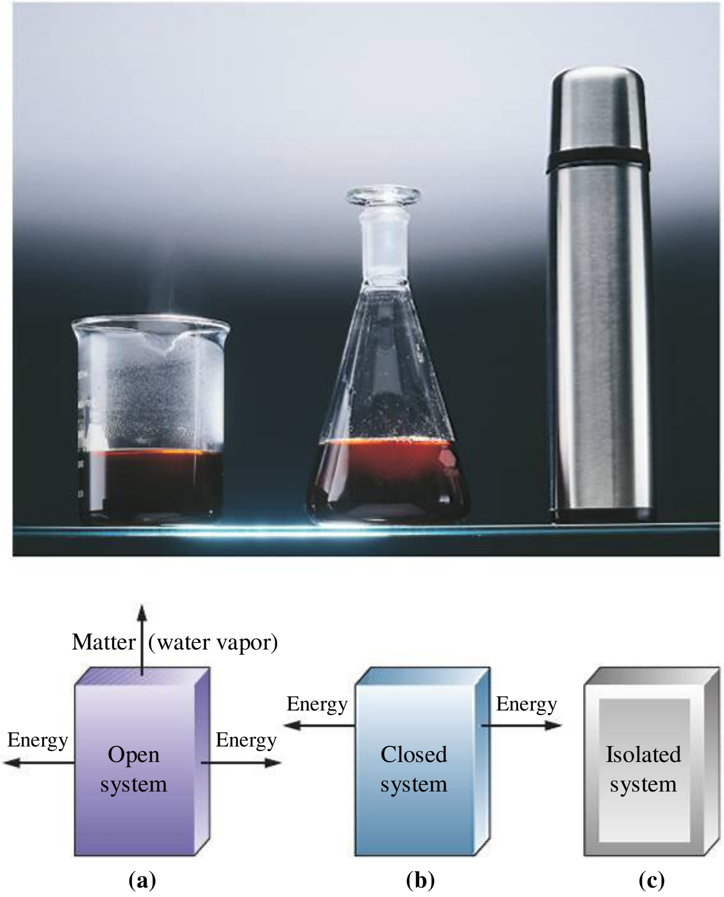
In this section, we introduce and define some very basic terms. Most are discussed in greater detail in later sections, and your understanding of these terms should grow as you proceed through the chapter.

Let us think of the universe as being comprised of a system and its surroundings. A **system** is the part of the universe chosen for study, and it can be as large as all the oceans on Earth or as small as the contents of a beaker. Most of the systems we will examine will be small and we will look, particularly, at the transfer of *energy* (as heat and work) and *matter* between the system and its surroundings. The **surroundings** are that part of the universe outside the system with which the system interacts. Figure 7-1 pictures three common systems: first, as we see them and, then, in an abstract form that chemists commonly use. An **open system** freely exchanges energy and matter with its surroundings (Fig. 7-1a). A **closed system** can exchange energy, but not matter, with its surroundings (Fig. 7-1b). An **isolated system** does not interact with its surroundings (approximated in Figure 7-1c).

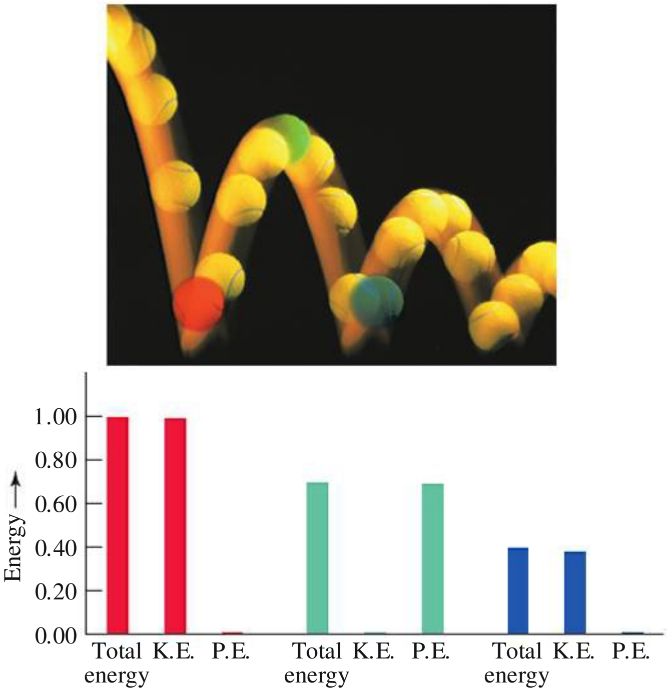


▲ **Isolated system**
Neither energy nor matter is transferred between the system and its surroundings.

The remainder of this section says more, in a general way, about energy and its relationship to work. Like many other scientific terms, *energy* is derived from Greek. It means "work within." **Energy** is the capacity to do work. **Work** is done when a force acts through a distance. Moving objects do work when they slow down or are stopped. Thus, when one billiard ball strikes another and sets it in motion, work is done. The energy of a moving object is called **kinetic energy** (the word *kinetic* means "motion" in Greek). We can see the relationship between work and energy by comparing the units for these two quantities. The kinetic energy (e_k) of an object is based on its mass (m) and



▶ FIGURE 7-1
Systems and their surroundings
(a) *Open system.* The beaker of hot coffee transfers energy to the surroundings—it loses heat as it cools. Matter is also transferred in the form of water vapor. **(b)** *Closed system.* The flask of hot coffee transfers energy (heat) to the surroundings as it cools. Because the flask is stoppered, no water vapor escapes and no matter is transferred. **(c)** *Isolated system.* Hot coffee in an insulated container approximates an isolated system. No water vapor escapes, and, for a time at least, little heat is transferred to the surroundings. (Eventually, though, the coffee in the container cools to room temperature.)



◀ FIGURE 7-2
Potential energy (P.E.) and kinetic energy (K.E.)
The energy of the bouncing tennis ball changes continuously from potential to kinetic energy and back again. The maximum potential energy is at the top of each bounce, and the maximum kinetic energy occurs at the moment of impact. The sum of P.E. and K.E. decreases with each bounce as the thermal energies of the ball and the surroundings increase. The ball soon comes to rest. The bar graph below the bouncing balls illustrates the relative contributions that the kinetic and potential energy make to the total energy for each ball position. The red bars correspond to the red ball, green bars correspond to the green ball and the blue bars correspond to the blue ball.

velocity (u) through the first equation below; work (w) is related to force $[\text{mass}\,(m) \times \text{acceleration}\,(a)]$ and distance (d) by the second equation.

$$
\begin{aligned}
e_k &= \tfrac{1}{2}mu^2 \\
w &= m \times a \times d \qquad (7.1)
\end{aligned}
$$

When mass, speed, acceleration, and distance are expressed in SI units, the units of both kinetic energy and work will be $\text{kg m}^2\,\text{s}^{-2}$, which is the SI unit of energy—the *joule* (J). That is, $1\text{ J} = 1\text{ kg m}^2\,\text{s}^{-2}$.

◀ As discussed in Appendix B-1, the SI unit for acceleration is m s^{-2}. We encountered this unit previously (page 194)—the acceleration due to gravity was given as $g = 9.80665\text{ m s}^{-2}$.

The bouncing ball in Figure 7-2 suggests something about the nature of energy and work. First, to lift the ball to the starting position, we have to apply a force through a distance (to overcome the force of gravity). The work we do is "stored" in the ball as energy. This stored energy has the potential to do work when released and is therefore called potential energy. **Potential energy** is energy resulting from condition, position, or composition; it is an energy associated with forces of attraction or repulsion between objects.

When we release the ball, it is pulled toward Earth's center by the force of gravity—it falls. Potential energy is converted to kinetic energy during this fall. The kinetic energy reaches its maximum just as the ball strikes the surface. On its rebound, the kinetic energy of the ball decreases (the ball slows down), and its potential energy increases (the ball rises). If the collision of the ball with the surface were perfectly *elastic*, like collisions between molecules in the kinetic-molecular theory, the sum of the potential and kinetic energies of the ball would remain constant. The ball would reach the same maximum height on each rebound, and it would bounce forever. But we know this doesn't happen—the bouncing ball soon comes to rest. All the energy originally invested in the ball as potential energy (by raising it to its initial position) eventually appears as additional kinetic energy of the atoms and molecules that make up the ball, the surface, and the surrounding air. This kinetic energy associated with random molecular motion is called **thermal energy**.

◀ A unit of work, heat, and energy is the joule, but work and heat are not forms of energy but *processes* by which the energy of a system is changed.

In general, thermal energy is proportional to the temperature of a system, as suggested by the kinetic theory of gases. The more vigorous the motion of the molecules in the system, the hotter the sample and the greater is its thermal energy. However, the thermal energy of a system also depends on the number of particles present, so that a small sample at a high temperature (for example, a cup of coffee at 75 °C) may have less thermal energy than a larger sample at a lower temperature (for example, a swimming pool at 30 °C). Thus, temperature and thermal energy must be carefully distinguished. Equally important, we need to distinguish between energy changes produced by the action of forces through distances—*work*—and those involving the transfer of thermal energy—*heat*.

7-1 CONCEPT ASSESSMENT

Consider the following situations: a stick of dynamite exploding deep within a mountain cavern, the titration of an acid with base in a laboratory, and a cylinder of a steam engine with all of its valves closed. To what type of thermodynamic systems do these situations correspond?

7-2 Heat

Heat is energy transferred between a system and its surroundings as a result of a temperature difference. Energy that passes from a warmer body (with a higher temperature) to a colder body (with a lower temperature) is transferred as heat. At the molecular level, molecules of the warmer body, through collisions, lose kinetic energy to those of the colder body. Thermal energy is transferred—"heat flows"—until the average molecular kinetic energies of the two bodies become the same, until the temperatures become equal. Heat, like work, describes energy in transit between a system and its surroundings.

▲ **James Joule (1818–1889)—an amateur scientist**
Joule's primary occupation was running a brewery, but he also conducted scientific research in a home laboratory. His precise measurements of quantities of heat formed the basis of the law of conservation of energy.

Not only can heat transfer cause a change in temperature but, in some instances, it can also change a state of matter. For example, when a solid is heated, the molecules, atoms, or ions of the solid move with greater vigor and eventually break free from their neighbors by overcoming the attractive forces between them. Energy is required to overcome these attractive forces. During the process of melting, the temperature remains constant as a thermal energy transfer (heat) is used to overcome the forces holding the solid together. A process occurring at a constant temperature is said to be *isothermal*. Once a solid has melted completely, any further heat flow will raise the temperature of the resulting liquid.

Although we commonly use expressions like "heat is lost," "heat is gained," "heat flows," and "the system loses heat to the surroundings," you should not take these statements to mean that a system contains heat. It does not. The energy content of a system, as we shall see in Section 7-5, is a quantity called the *internal energy*. Heat is simply a form in which a quantity of energy may be *transferred* across a boundary between a system and its surroundings.

It is reasonable to expect that the quantity of heat, q, required to change the temperature of a substance depends on

- how much the temperature is to be changed
- the quantity of substance
- the nature of the substance (type of atoms or molecules)

Historically, the quantity of heat required to change the temperature of one gram of water by one degree Celsius has been called the **calorie** (**cal**). The calorie is a small unit of energy, and the unit *kilocalorie* (kcal) has also been widely used. The SI unit for heat is simply the basic SI energy unit, the joule (J).

$$1\ \text{cal} = 4.184\ \text{J} \qquad \textbf{(7.2)}$$

Although the joule is used almost exclusively in this text, the calorie is widely encountered in older scientific literature. In the United States, the kilocalorie is commonly used for measuring the energy content of foods (see Focus On feature for Chapter 7 on www.masteringchemistry.com).

The quantity of heat required to change the temperature of a system by one degree is called the **heat capacity** of the system. If the system is a mole of substance, the term *molar heat capacity* is applicable. If the system is one gram of substance, the applicable term is *specific heat capacity*, or more commonly, **specific heat** (sp ht).* The specific heats of substances are somewhat temperature dependent. At 25 °C, the specific heat of water is

$$\frac{4.18\ \text{J}}{\text{g}\ ^\circ\text{C}} = 4.18\ \text{J g}^{-1}\ ^\circ\text{C}^{-1} \qquad \textbf{(7.3)}$$

In Example 7-1, the objective is to calculate a quantity of heat based on the amount of a substance, the specific heat of that substance, and its temperature change.

EXAMPLE 7-1 Calculating a Quantity of Heat

How much heat is required to raise the temperature of 7.35 g of water from 21.0 to 98.0 °C? (Assume the specific heat of water is $4.18\ \text{J g}^{-1}\ ^\circ\text{C}^{-1}$ throughout this temperature range.)

Analyze

To answer this question, we begin by multiplying the specific heat capacity by the mass of water to obtain the heat capacity of the system. To find the amount of heat required to produce the desired temperature change we multiply the heat capacity by the temperature difference.

Solve

The specific heat is the heat capacity of 1.00 g water:

$$\frac{4.18\ \text{J}}{\text{g water}\ ^\circ\text{C}}$$

The heat capacity of the system (7.35 g water) is

$$7.35\ \cancel{\text{g water}} \times \frac{4.18\ \text{J}}{\cancel{\text{g water}}\ ^\circ\text{C}} = 30.7\,\frac{\text{J}}{^\circ\text{C}}$$

The required temperature change in the system is

$$(98.0 - 21.0)\ ^\circ\text{C} = 77.0\ ^\circ\text{C}$$

The heat required to produce this temperature change is

$$30.7\,\frac{\text{J}}{\cancel{^\circ\text{C}}} \times 77.0\ \cancel{^\circ\text{C}} = 2.36 \times 10^3\ \text{J}$$

Assess

Remember that specific heat is a quantity that depends on the amount of material. Also note that the change in temperature is determined by subtracting the initial temperature from the final temperature. This will be important in determining the sign on the value you determine for heat, as will become apparent in the next section.

PRACTICE EXAMPLE A: How much heat, in kilojoules (kJ), is required to raise the temperature of 237 g of cold water from 4.0 to 37.0 °C (body temperature)?

PRACTICE EXAMPLE B: How much heat, in kilojoules (kJ), is required to raise the temperature of 2.50 kg Hg(l) from −20.0 to −6.0 °C? Assume a density of 13.6 g/mL and a molar heat capacity of $28.0\ \text{J mol}^{-1}\ ^\circ\text{C}^{-1}$ for Hg(l).

The line of reasoning used in Example 7-1 can be summarized in equation (7.5), which relates a quantity of heat to the mass of a substance, its specific heat, and the temperature change.

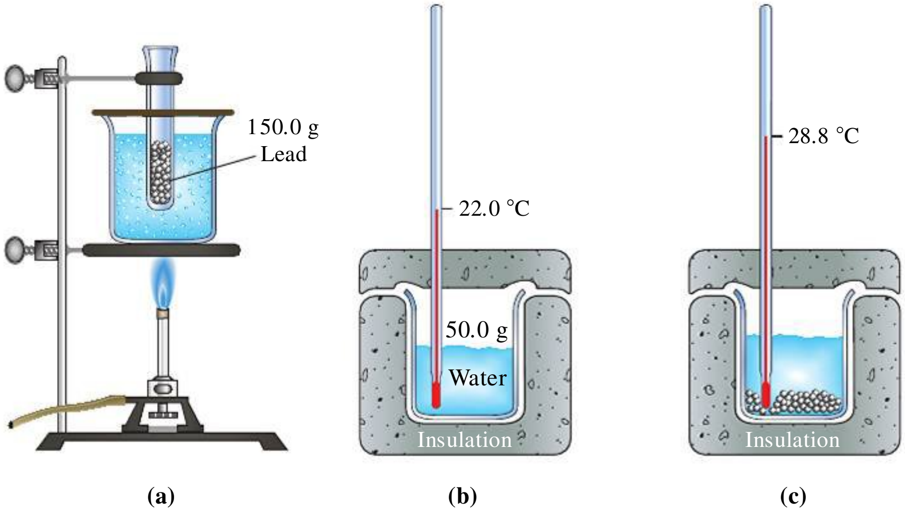
$$\text{quantity of heat} = \underbrace{\text{mass of substance} \times \text{specific heat}}_{\text{heat capacity} \,=\, C} \times \text{temperature change} \qquad \textbf{(7.4)}$$

$$q = m \times \text{specific heat} \times \Delta T = C \times \Delta T \qquad \textbf{(7.5)}$$

◀ The Greek letter delta, Δ, indicates a *change* in some quantity.

---

*The original meaning of specific heat was that of a *ratio*: the quantity of heat required to change the temperature of a mass of substance divided by the quantity of heat required to produce the same temperature change in the same mass of water—this definition would make specific heat dimensionless. The meaning given here is more commonly used.



▶ FIGURE 7-3
Determining the specific heat of lead—Example 7-2 illustrated
(a) A 150.0 g sample of lead is heated to the temperature of boiling water (100.0 °C). **(b)** A 50.0 g sample of water is added to a thermally insulated beaker, and its temperature is found to be 22.0 °C. **(c)** The hot lead is dumped into the cold water, and the temperature of the final lead–water mixture is 28.8 °C.

▶ The symbol > means "greater than," and < means "less than."

In equation (7.5), the temperature change is expressed as $\Delta T = T_f - T_i$, where T_f is the final temperature and T_i is the initial temperature. When the temperature of a system increases ($T_f > T_i$), ΔT is *positive*. A positive q signifies that heat is absorbed or *gained* by the system. When the temperature of a system decreases ($T_f < T_i$), ΔT is *negative*. A negative q signifies that heat is evolved or *lost* by the system.

Another idea that enters into calculations of quantities of heat is the **law of conservation of energy**: In interactions between a system and its surroundings, the total energy remains *constant*—energy is neither created nor destroyed. Applied to the exchange of heat, this means that

$$q_{\text{system}} + q_{\text{surroundings}} = 0 \qquad \textbf{(7.6)}$$

Thus, heat *gained* by a system is *lost* by its surroundings, and vice versa.

$$q_{\text{system}} = -q_{\text{surroundings}} \qquad \textbf{(7.7)}$$

Experimental Determination of Specific Heats

Let us consider how the law of conservation of energy is used in the experiment outlined in Figure 7-3. The object is to determine the specific heat of lead. The transfer of energy, as heat, from the lead to the cooler water causes the temperature of the lead to decrease and that of the water to increase, until the lead and water are at the same temperature. Either the lead or the water can be considered the system. If we consider lead to be the system, we can write $q_{\text{lead}} = q_{\text{system}}$. Furthermore, if the lead and water are maintained in a thermally insulated enclosure, we can assume that $q_{\text{water}} = q_{\text{surroundings}}$. Then, applying equation (7.7), we have

$$q_{\text{lead}} = -q_{\text{water}} \qquad \textbf{(7.8)}$$

We complete the calculation in Example 7-2.

EXAMPLE 7-2 Determining a Specific Heat from Experimental Data

Use data presented in Figure 7-3 to calculate the specific heat of lead.

Analyze

Keep in mind that if we know any four of the five quantities—q, m, specific heat, T_f, T_i—we can solve equation (7.5) for the remaining one. We know from Figure 7-3 that a known quantity of lead is heated and then dumped into a known amount of water at a known temperature, which is the initial temperature. Once the system comes to equilibrium, the water temperature is the final temperature. In this type of question, we will use equation (7.5).

Solve

First, use equation (7.5) to calculate q_{water}.

$$q_{\text{water}} = 50.0\text{ g water} \times \frac{4.18\text{ J}}{\text{g water }°\text{C}} \times (28.8 - 22.0)\ °\text{C} = 1.4 \times 10^3\text{ J}$$

From equation (7.8) we can write

$$q_{\text{lead}} = -q_{\text{water}} = -1.4 \times 10^3\text{ J}$$

Now, from equation (7.5) again, we obtain

$$q_{\text{lead}} = 150.0\text{ g lead} \times \text{specific heat of lead} \times (28.8 - 100.0)\ °\text{C} = -1.4 \times 10^3\text{ J}$$

$$\text{specific heat of lead} = \frac{-1.4 \times 10^3\text{ J}}{150.0\text{ g lead} \times (28.8 - 100.0)\ °\text{C}} = \frac{-1.4 \times 10^3\text{ J}}{150.0\text{ g lead} \times -71.2\ °\text{C}} = 0.13\text{ J g}^{-1}\,°\text{C}^{-1}$$

Assess

The key concept to recognize is that energy, in the form of heat, flowed from the lead, which is our system, to the water, which is part of the surroundings. A quick way to make sure that we have done the problem correctly is to check the sign on the final answer. For specific heat, the sign should always be positive and have the units of $\text{J g}^{-1}\,°\text{C}^{-1}$.

PRACTICE EXAMPLE A: When 1.00 kg lead (specific heat $= 0.13\text{ J g}^{-1}\,°\text{C}^{-1}$) at 100.0 °C is added to a quantity of water at 28.5 °C, the final temperature of the lead–water mixture is 35.2 °C. What is the mass of water present?

PRACTICE EXAMPLE B: A 100.0 g copper sample (specific heat $= 0.385\text{ J g}^{-1}\,°\text{C}^{-1}$) at 100.0 °C is added to 50.0 g water at 26.5 °C. What is the final temperature of the copper–water mixture?

7-2 CONCEPT ASSESSMENT

With a minimum of calculation, estimate the final temperature reached when 100.0 mL of water at 10.00 °C is added to 200.0 mL of water at 70.00 °C. What basic principle did you use and what assumptions did you make in arriving at this estimate?

Specific Heats of Some Substances

Table 7.1 lists specific heats of some substances. For many substances, the specific heat is less than 1 $\text{J g}^{-1}\,°\text{C}^{-1}$. A few substances, $H_2O(l)$ in particular, have specific heats that are substantially larger. Can we explain why liquid water has a high specific heat? The answer is most certainly yes, but the explanation relies on concepts we have not yet discussed. The fact that water molecules form hydrogen bonds (which we discuss in Chapter 12) is an important part of the reason why water has a large specific heat value.

Because of their greater complexity at the molecular level, compounds generally have more ways of storing internal energy than do the elements; they tend to have higher specific heats. Water, for example, has a specific heat that is more than 30 times as great as that of lead. We need a much larger quantity of heat to change the temperature of a sample of water than of an equal mass of a metal.

An environmental consequence of the high specific heat of water is found in the effect of large lakes on local climates. Because a lake takes much longer to heat up in summer and cool down in winter than other types of terrain, lakeside communities tend to be cooler in summer and warmer in winter than communities more distant from the lake.

7-3 CONCEPT ASSESSMENT

Two objects of the same mass absorb the same amount of heat when heated in a flame, but the temperature of one object increases more than the temperature of the other. Which object has the greater specific heat?

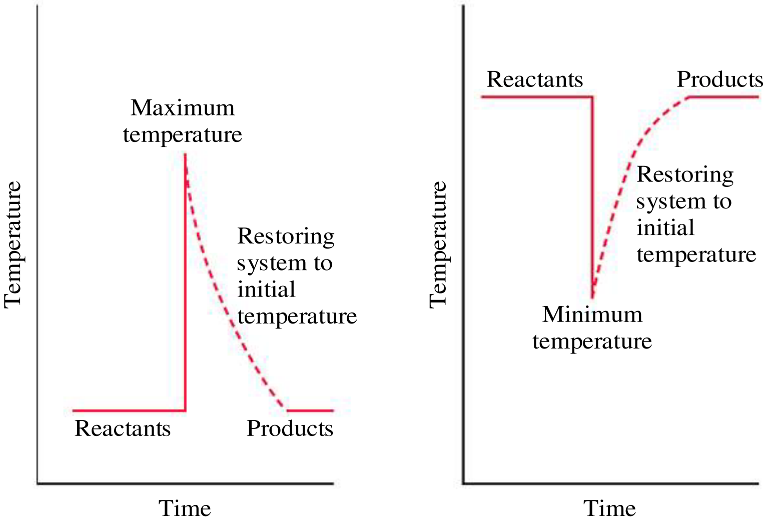
7-3 Heats of Reaction and Calorimetry

In Section 7-1, we introduced the notion of *thermal energy*—kinetic energy associated with random molecular motion. Another type of energy that contributes to the internal energy of a system is **chemical energy**. This is energy associated with chemical bonds and intermolecular attractions. If we think of a chemical reaction as a process in which some chemical bonds are broken and others are formed, then, in general, we expect the chemical energy of a system to change as a result of a reaction. Furthermore, we might expect some of this energy change to appear as heat. A **heat of reaction**, q_{rxn}, is the quantity of heat exchanged between a system and its surroundings when a chemical reaction occurs within the system at *constant temperature*. One of the most common reactions studied is the combustion reaction. This is such a common reaction that we often refer to the *heat of combustion* when describing the heat released by a combustion reaction.

If a reaction occurs in an *isolated* system, that is, one that exchanges no matter or energy with its surroundings, the reaction produces a change in the thermal energy of the system—the temperature either increases or decreases. Imagine that the previously isolated system is allowed to interact with its surroundings. The heat of reaction is the quantity of heat exchanged between the system and its surroundings as the system is restored to its initial temperature (Fig. 7-4). In actual practice, we do not physically restore the system to its initial temperature. Instead, we calculate the quantity of heat that *would be* exchanged in this restoration. To do this, a probe (thermometer) is placed within the system to record the temperature change produced by the reaction. Then, we use the temperature change and other system data to calculate the heat of reaction that would have occurred at constant temperature.

Two widely used terms related to heats of reaction are exothermic and endothermic reactions. An **exothermic reaction** is one that produces a temperature increase in an isolated system or, in a nonisolated system, gives off heat to the surroundings. For an exothermic reaction, the heat of reaction is a negative quantity ($q_{\text{rxn}} < 0$). In an **endothermic reaction**, the corresponding situation is a temperature decrease in an isolated system or a gain of heat from the surroundings by a nonisolated system. In this case, the heat of reaction is a positive quantity ($q_{\text{rxn}} > 0$). Heats of reaction are experimentally determined in a **calorimeter**, a device for measuring quantities of heat. We will consider two types of calorimeters in this section, and we will treat both of them as *isolated* systems.



(a) Exothermic reaction **(b) Endothermic reaction**

▶ FIGURE 7-4
Conceptualizing a heat of reaction at constant temperature
The solid lines indicate the initial temperature and the **(a)** maximum and **(b)** minimum temperature reached in an isolated system, in an exothermic and an endothermic reaction, respectively. The broken lines represent pathways to restoring the system to the initial temperature. The heat of reaction is the heat lost or gained by the system in this restoration.

(a) (b)

◀ **Exothermic and endothermic reactions**
(a) An exothermic reaction. Slaked lime, $Ca(OH)_2$, is produced by the action of water on quicklime, (CaO). The reactants are mixed at room temperature, but the temperature of the mixture rises to 40.5 °C.

$$CaO(s) + H_2O(l) \longrightarrow Ca(OH)_2(s)$$

(b) An endothermic reaction. $Ba(OH)_2 \cdot 8\,H_2O(s)$ and $NH_4Cl(s)$ are mixed at room temperature, and the temperature falls to 5.8 °C in the reaction.

$$Ba(OH)_2 \cdot 8\,H_2O(s) + 2\,NH_4Cl(s) \longrightarrow BaCl_2 \cdot 2H_2O(s) + 2\,NH_3(aq) + 8\,H_2O(l)$$

Bomb Calorimetry

Figure 7-5 shows a **bomb calorimeter**, which is ideally suited for measuring the heat evolved in a combustion reaction. The system is everything within the double-walled outer jacket of the calorimeter. This includes the bomb and its contents, the water in which the bomb is immersed, the thermometer, the stirrer, and so on. The system is *isolated* from its surroundings. When the combustion reaction occurs, chemical energy is converted to thermal energy, and the temperature of the system rises. The heat of reaction, as described earlier, is the quantity of heat that the system would have to *lose* to its surroundings to be restored to its initial temperature. This quantity of heat, in turn, is just the *negative* of the thermal energy gained by the calorimeter and its contents ($q_{calorim}$).

$$q_{rxn} = -q_{calorim}\,(\text{where } q_{calorim} = q_{bomb} + q_{water} \cdots) \tag{7.9}$$

KEEP IN MIND

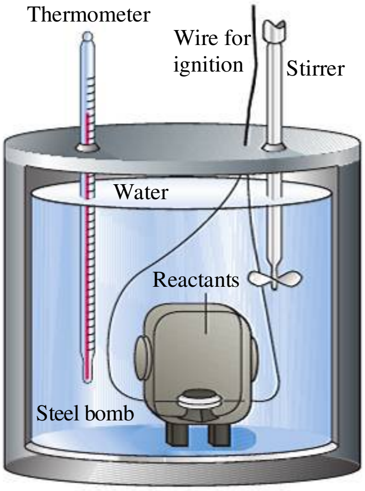
that the temperature of a reaction mixture usually changes during a reaction, so the mixture must be returned to the initial temperature (actually or hypothetically) before we assess how much heat is exchanged with the surroundings.

If the calorimeter is assembled in exactly the same way each time we use it—that is, use the same bomb, the same quantity of water, and so on—we can define a *heat capacity of the calorimeter*. This is the quantity of heat required to raise the temperature of the calorimeter assembly by one degree Celsius. When this heat capacity is multiplied by the observed temperature change, we get $q_{calorim}$.

◀ The heat capacity of a bomb calorimeter must be determined by experiment.

$$q_{calorim} = \text{heat capacity of calorim} \times \Delta T \tag{7.10}$$

And from $q_{calorim}$, we then establish q_{rxn}, as in Example 7-3, where we determine the heat of combustion of sucrose (table sugar).



◀ FIGURE 7-5
A bomb calorimeter assembly
An iron wire is embedded in the sample in the lower half of the bomb. The bomb is assembled and filled with $O_2(g)$ at high pressure. The assembled bomb is immersed in water in the calorimeter, and the initial temperature is measured. A short pulse of electric current heats the sample, causing it to ignite. The final temperature of the calorimeter assembly is determined after the combustion. Because the bomb confines the reaction mixture to a fixed volume, the reaction is said to occur at *constant volume*. The significance of this fact is discussed on page 259.

EXAMPLE 7-3 Using Bomb Calorimetry Data to Determine a Heat of Reaction

The combustion of 1.010 g sucrose, $C_{12}H_{22}O_{11}$, in a bomb calorimeter causes the temperature to rise from 24.92 to 28.33 °C. The heat capacity of the calorimeter assembly is 4.90 kJ/°C. **(a)** What is the heat of combustion of sucrose expressed in kilojoules per mole of $C_{12}H_{22}O_{11}$? **(b)** Verify the claim of sugar producers that one teaspoon of sugar (about 4.8 g) contains only 19 Calories.

Analyze

We are given a specific heat and two temperatures, the initial and the final, which indicate that we are to use equation (7.5). In these kinds of experiments one obtains the amount of heat generated by the reaction by measuring the temperature change in the surroundings. This means that $q_{\text{rxn}} = -q_{\text{calorim}}$.

Solve

(a) Calculate q_{calorim} with equation (7.10).

$$q_{\text{calorim}} = 4.90\ \text{kJ/°C} \times (28.33 - 24.92)\ \text{°C} = (4.90 \times 3.41)\ \text{kJ} = 16.7\ \text{kJ}$$

Now, using equation (7.9), we get

$$q_{\text{rxn}} = -q_{\text{calorim}} = -16.7\ \text{kJ}$$

This is the heat of combustion of the 1.010 g sample.
Per gram $C_{12}H_{22}O_{11}$:

$$q_{\text{rxn}} = \frac{-16.7\ \text{kJ}}{1.010\ \text{g}\ C_{12}H_{22}O_{11}} = -16.5\ \text{kJ/g}\ C_{12}H_{22}O_{11}$$

Per mole $C_{12}H_{22}O_{11}$:

$$q_{\text{rxn}} = \frac{-16.5\ \text{kJ}}{\text{g}\ C_{12}H_{22}O_{11}} \times \frac{342.3\ \text{g}\ C_{12}H_{22}O_{11}}{1\ \text{mol}\ C_{12}H_{22}O_{11}} = -5.65 \times 10^3\ \text{kJ/mol}\ C_{12}H_{22}O_{11}$$

(b) To determine the caloric content of sucrose, we can use the heat of combustion per gram of sucrose determined in part **(a)**, together with a factor to convert from kilojoules to kilocalories. (Because 1 cal = 4.184 J, 1 kcal = 4.184 kJ.)

$$?\ \text{kcal} = \frac{4.8\ \text{g}\ C_{12}H_{22}O_{11}}{\text{tsp}} \times \frac{-16.5\ \text{kJ}}{\text{g}\ C_{12}H_{22}O_{11}} \times \frac{1\ \text{kcal}}{4.184\ \text{kJ}} = \frac{-19\ \text{kcal}}{\text{tsp}}$$

1 food Calorie (1 Calorie with a capital C) is actually 1000 cal, or 1 kcal. Therefore, 19 kcal = 19 Calories. The claim is justified.

Assess

A combustion reaction is an exothermic reaction, which means that energy flows, in the form of heat, from the reaction system to the surroundings. Therefore, the q for a combustion reaction is negative.

PRACTICE EXAMPLE A: Vanillin is a natural constituent of vanilla. It is also manufactured for use in artificial vanilla flavoring. The combustion of 1.013 g of vanillin, $C_8H_8O_3$, in the same bomb calorimeter as in Example 7-3 causes the temperature to rise from 24.89 to 30.09 °C. What is the heat of combustion of vanillin, expressed in kilojoules per mole?

PRACTICE EXAMPLE B: The heat of combustion of benzoic acid is −26.42 kJ/g. The combustion of a 1.176 g sample of benzoic acid causes a temperature *increase* of 4.96°C in a bomb calorimeter assembly. What is the heat capacity of the assembly?

The "Coffee-Cup" Calorimeter

In the general chemistry laboratory you are much more likely to run into the simple calorimeter pictured in Figure 7-6 (on page 252) than a bomb calorimeter. We mix the reactants (generally in aqueous solution) in a Styrofoam cup and measure the temperature change. Styrofoam is a good heat insulator, so there is very little heat transfer between the cup and the surrounding air. We treat the system—the cup and its contents—as an *isolated* system.

As with the bomb calorimeter, the heat of reaction is defined as the quantity of heat that would be exchanged with the surroundings in restoring the calorimeter to its initial temperature. But, again, the calorimeter is not physically restored to its initial conditions. We simply take the heat of reaction to be the *negative* of the quantity of heat producing the temperature change in the calorimeter. That is, we use equation (7.9): $q_{\text{rxn}} = -q_{\text{calorim}}$.

In Example 7-4, we make certain assumptions to simplify the calculation, but for more precise measurements, these assumptions would not be made (see Exercise 25).

EXAMPLE 7-4 Determining a Heat of Reaction from Calorimetric Data

In the neutralization of a strong acid with a strong base, the essential reaction is the combination of $H^+(aq)$ and $OH^-(aq)$ to form water (recall page 165).

$$H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$$

Two solutions, 25.00 mL of 2.50 M HCl(aq) and 25.00 mL of 2.50 M NaOH(aq), both initially at 21.1 °C, are added to a Styrofoam-cup calorimeter and allowed to react. The temperature rises to 37.8 °C. Determine the heat of the neutralization reaction, expressed per mole of H_2O formed. Is the reaction endothermic or exothermic?

Analyze

In addition to assuming that the calorimeter is an isolated system, assume that all there is in the system to absorb heat is 50.00 mL of water. This assumption ignores the fact that 0.0625 mol each of NaCl and H_2O are formed in the reaction, that the density of the resulting NaCl(aq) is not exactly 1.00 g/mL, and that its specific heat is not exactly $4.18\ \text{J g}^{-1}\,{}^\circ\text{C}^{-1}$. Also, ignore the small heat capacity of the Styrofoam cup itself.

Because the reaction is a neutralization reaction, let us call the heat of reaction q_{neutr}. Now, according to equation (7.9), $q_{\text{neutr}} = -q_{\text{calorim}}$, and if we make the assumptions described above, we can solve the problem.

Solve

We begin with

$$q_{\text{calorim}} = 50.00\ \text{mL} \times \frac{1.00\ \text{g}}{\text{mL}} \times \frac{4.18\ \text{J}}{\text{g}\,{}^\circ\text{C}} \times (37.8 - 21.1)\ {}^\circ\text{C} = 3.5 \times 10^3\ \text{J}$$

$$q_{\text{neutr}} = -q_{\text{calorim}} = -3.5 \times 10^3\ \text{J} = -3.5\ \text{kJ}$$

In 25.00 mL of 2.50 M HCl, the amount of H^+ is

$$?\ \text{mol H}^+ = 25.00\ \text{mL} \times \frac{1\ \text{L}}{1000\ \text{mL}} \times \frac{2.50\ \text{mol}}{1\ \text{L}} \times \frac{1\ \text{mol H}^+}{1\ \text{mol HCl}} = 0.0625\ \text{mol H}^+$$

Similarly, in 25.00 mL of 2.50 M NaOH there is 0.0625 mol OH^-. Thus, the H^+ and the OH^- combine to form 0.0625 mol H_2O. (The two reactants are in *stoichiometric* proportions; neither is in excess.)

The amount of heat produced per mole of H_2O is

$$q_{\text{neutr}} = \frac{-3.5\ \text{kJ}}{0.0625\ \text{mol H}_2\text{O}} = -56\ \text{kJ/mol H}_2\text{O}$$

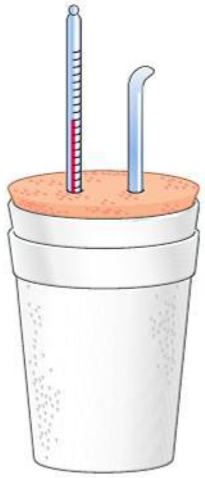
Assess

Because q_{neutr} is a *negative* quantity, the neutralization reaction is *exothermic*. Even though, in this example, we considered a specific reaction, the result $q_{\text{neutr}} = -56$ kJ/mol is more general. We will obtain the same value of q_{neutr} by considering any strong acid-strong base reaction because the net ionic equation is the same for all strong acid-strong base reactions.

PRACTICE EXAMPLE A: Two solutions, 100.0 mL of 1.00 M $AgNO_3(aq)$ and 100.0 mL of 1.00 M NaCl(aq), both initially at 22.4 °C, are added to a Styrofoam-cup calorimeter and allowed to react. The temperature rises to 30.2 °C. Determine q_{rxn} per mole of AgCl(s) in the reaction.

$$Ag^+(aq) + Cl^-(aq) \longrightarrow AgCl(s)$$

PRACTICE EXAMPLE B: Two solutions, 100.0 mL of 1.020 M HCl and 50.0 mL of 1.988 M NaOH, both initially at 24.52 °C, are mixed in a Styrofoam-cup calorimeter. What will be the final temperature of the mixture? Make the same assumptions, and use the heat of neutralization established in Example 7-4. [*Hint:* Which is the limiting reactant?]



▲ FIGURE 7-6
A Styrofoam "coffee-cup" calorimeter
The reaction mixture is in the inner cup. The outer cup provides additional thermal insulation from the surrounding air. The cup is closed off with a cork stopper through which a thermometer and a stirrer are inserted and immersed into the reaction mixture. The reaction in the calorimeter occurs under the *constant pressure* of the atmosphere. We consider the difference between constant-volume and constant-pressure reactions in Section 7-6.

7-4 CONCEPT ASSESSMENT

How do we determine the specific heat of the bomb calorimeter or the solution calorimeter (coffee-cup calorimeter)?

7-4 Work

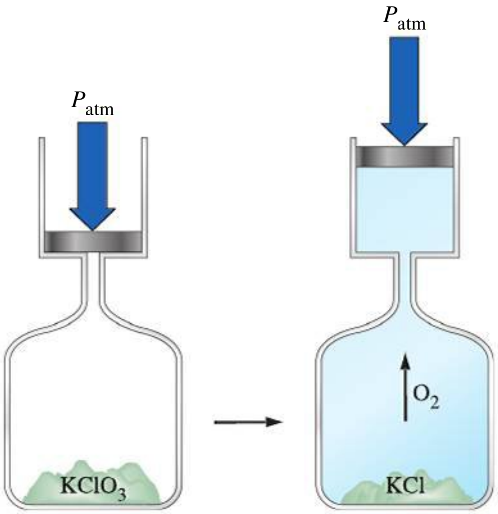
We have just learned that heat effects generally accompany chemical reactions. In some reactions, work is also involved—that is, the system may do work on its surroundings or vice versa. Consider the decomposition of potassium chlorate to potassium chloride and oxygen. Suppose that this decomposition is carried out in the strange vessel pictured in Figure 7-7. The walls of the container resist moving under the pressure of the expanding $O_2(g)$ except for the piston that closes off the cylindrical top of the vessel. The pressure of the $O_2(g)$ exceeds the atmospheric pressure and the piston is lifted—the system does work on the surroundings. Can you see that even if the piston were removed, work still would be done as the expanding $O_2(g)$ pushed aside other atmospheric gases? Work involved in the expansion or compression of gases is called **pressure–volume work**. Pressure–volume, or P–V, work is the type of work performed by explosives and by the gases formed in the combustion of gasoline in an automobile engine.

Now let us switch to a somewhat simpler situation to see how to calculate a quantity of P–V work.

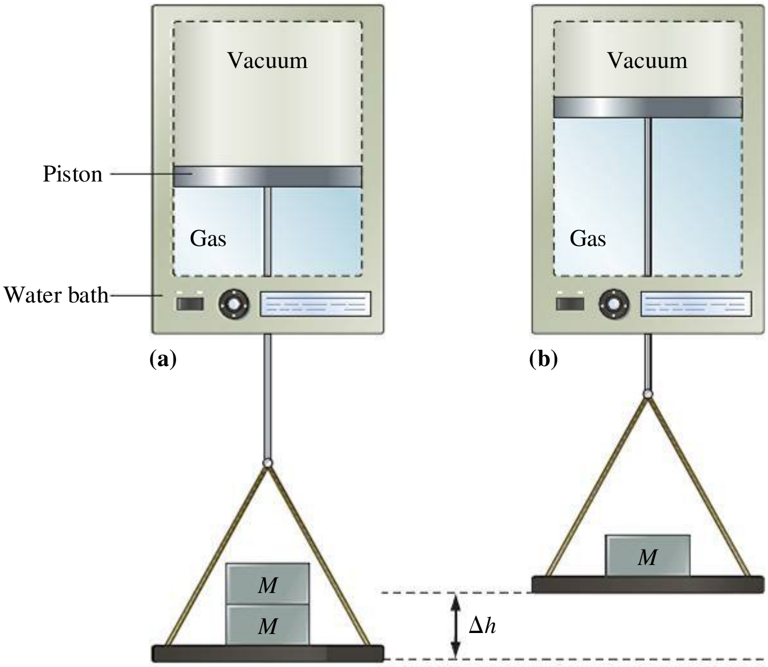
In the hypothetical apparatus pictured in Figure 7-8(a), a weightless piston is attached to a weightless wire support, to which is attached a weightless pan. On the pan are two identical weights just sufficient to stop the gas from expanding. The gas is confined by the cylinder walls and piston, and the space above the piston is a vacuum. The cylinder is contained in a constant-temperature water bath, which keeps the temperature of the gas constant. Now imagine that one of the two weights is removed, leaving half the original mass on the pan. Let us call this remaining mass M. The gas will expand and the remaining weight will move against gravity, the situation represented by Figure 7-8(b). After the expansion, we find that the piston has risen through a vertical distance, Δh; that the volume of gas has doubled; and that the pressure of the gas has decreased.

Now let us see how pressure and volume enter into calculating how much *pressure–volume* work the expanding gas does. First we can calculate the work done by the gas in moving the weight of mass M through a displacement Δh. Recall from equation (7.1) that the work can be calculated by

$$\text{work}\,(w) = \text{force}\,(M \times g) \times \text{distance}\,(\Delta h) = -M \times g \times \Delta h$$



▶ FIGURE 7-7
Illustrating work (expansion) during the chemical reaction $2\,KClO_3(s) \longrightarrow 2\,KCl(s) + 3\,O_2(g)$
The oxygen gas that is formed pushes back the weight and, in doing so, does work on the surroundings.



▲ FIGURE 7-8
Pressure–volume work
(a) In this hypothetical apparatus, a gas is confined by a massless piston of area A. A massless wire is attached to the piston and the gas is held back by two weights with a combined mass of $2M$ resting on the massless pan. The cylinder is immersed in a large water bath in order to keep the gas temperature constant. The initial state of the gas is $P_i = 2\,Mg/A$ with a volume V_i at temperature, T. **(b)** When the external pressure on the confined gas is suddenly lowered by removing one of the weights the gas expands, pushing the piston up by the distance, Δh. The increase in volume of the gas (ΔV) is the product of the cross-sectional area of the cylinder (A) and the distance (Δh). The final state of the gas is $P_f = Mg/A$, V_f, and T.

The magnitude of the force exerted by the weight is $M \times g$, where g is the acceleration due to gravity. The negative sign appears because the force is acting in a direction opposite to the piston's direction of motion.

Now recall equation (6.1)—pressure = force $(M \times g)$/area (A)—so that if the expression for work is multiplied by A/A we get

$$w = -\frac{M \times g}{A} \times \Delta h \times A = -P_{\text{ext}}\Delta V \qquad \textbf{(7.11)}$$

The "pressure" part of the pressure–volume work is seen to be the external pressure (P_{ext}) on the gas, which in our thought experiment is equal to the weight pulling down on the piston and is given by Mg/A. Note that the product of the area (A) and height (Δh) is equal to a volume—the volume change, ΔV, produced by the expansion.

Two significant features to note in equation (7.11) are the *negative* sign and the factor P_{ext}. The negative sign is necessary to conform to sign conventions that we will introduce in the next section. When a gas expands, ΔV is positive and w is negative, signifying that energy leaves the system as work. When a gas is compressed, ΔV is negative and w is positive, signifying that energy (as work) enters the system. P_{ext} is the *external* pressure—the pressure against which a system expands or the applied pressure that compresses a system. In many instances the internal pressure in a system will be essentially equal to the external pressure, in which case the pressure in equation (7.11) is expressed simply as P.

◀ Work is negative when energy is transferred out of the system and is positive when energy is transferred into the system. This is consistent with the signs associated with the heat of a reaction (q) during endothermic and exothermic processes.

▶ The unit atm L, often written as L atm, is the liter-atmosphere. The use of this unit still persists.

If pressure is stated in bars or atmospheres and volume in liters, the unit of work is bar L or atm L. However, the SI unit of work is the joule. To convert from bar L to J, or from atm L to J, we use one of the following relationships, both of which are *exact*.

$$1 \text{ bar L} = 100 \text{ J} \qquad 1 \text{ atm L} = 101.325 \text{ J}$$

These relationships are easily established by comparing values of the gas constant, R, given in Table 6.3. For example, because $R = 8.3145 \text{ J K}^{-1} \text{ mol}^{-1} = 0.083145 \text{ bar L K}^{-1} \text{ mol}^{-1}$, we have

$$\frac{8.3145 \text{ J } \cancel{\text{K}^{-1}} \, \cancel{\text{mol}^{-1}}}{0.083145 \text{ bar L } \cancel{\text{K}^{-1}} \, \cancel{\text{mol}^{-1}}} = 100 \frac{\text{J}}{\text{bar L}}$$

EXAMPLE 7-5 Calculating Pressure–Volume Work

Suppose the gas in Figure 7-8 is 0.100 mol He at 298 K, the two weights correspond to an external pressure of 2.40 atm in Figure 7-8(a), and the single weight in Figure 7-8(b) corresponds to an external pressure of 1.20 atm. How much work, in joules, is associated with the gas expansion at constant temperature?

Analyze

We are given enough data to calculate the initial and final gas volumes (note that the identity of the gas does not enter into the calculations because we are assuming ideal gas behavior). With these volumes, we can obtain ΔV. The external pressure in the pressure–volume work is the *final* pressure: 1.20 atm. The product $-P_{\text{ext}} \times \Delta V$ must be multiplied by a factor to convert work in liter-atmospheres to work in joules.

Solve

First calculate the initial and final volumes.

$$V_{\text{initial}} = \frac{nRT}{P_i} = \frac{0.100 \text{ mol} \times 0.0821 \text{ L atm mol}^{-1} \text{ K}^{-1} \times 298 \text{ K}}{2.40 \text{ atm}} = 1.02 \text{ L}$$

$$V_{\text{final}} = \frac{nRT}{P_f} = \frac{0.100 \text{ mol} \times 0.0821 \text{ L atm mol}^{-1} \text{ K}^{-1} \times 298 \text{ K}}{1.20 \text{ atm}} = 2.04 \text{ L}$$

$$\Delta V = V_f - V_i = 2.04 \text{ L} - 1.02 \text{ L} = 1.02 \text{ L}$$

$$w = -P_{\text{ext}} \times \Delta V = -1.20 \text{ atm} \times 1.02 \text{ L} \times \frac{101 \text{ J}}{1 \text{ L atm}} = -1.24 \times 10^2 \text{ J}$$

Assess

The negative value signifies that the expanding gas (i.e., the system) does work on its surroundings. Keep in mind that the ideal gas equation embodies Boyle's law: The volume of a fixed amount of gas at a fixed temperature is inversely proportional to the pressure. Thus, in Example 7-5 we could simply write that

$$V_f = 1.02 \text{ L} \times \frac{2.40 \text{ atm}}{1.20 \text{ atm}}$$

$$V_f = 2.04 \text{ L}$$

PRACTICE EXAMPLE A: How much work, in joules, is involved when 0.225 mol N_2 at a constant temperature of 23 °C is allowed to expand by 1.50 L in volume against an external pressure of 0.750 atm? [*Hint:* How much of this information is required?]

PRACTICE EXAMPLE B: How much work is done, in joules, when an external pressure of 2.50 atm is applied, at a constant temperature of 20.0 °C, to 50.0 g $N_2(g)$ in a 75.0 L cylinder? The cylinder is like that shown in Figure 7-8.

7-5 CONCEPT ASSESSMENT

A gas in a 1.0 L closed cylinder has an initial pressure of 10.0 bar. It has a final pressure of 5.0 bar. The volume of the cylinder remained constant during this time. What form of energy was transferred across the boundary to cause this change? In which direction did the energy flow?

This result confirms that 1 bar L = 100 J. How do we establish that 1 atm L is exactly 101.325 J? Recall that 1 atm is exactly 1.01325 bar (see Table 6.1). Thus, 1 atm L = 1.01325 bar L = 1.01325 × 100 J = 101.325 J.

7-5 The First Law of Thermodynamics

The absorption or evolution of heat and the performance of work require changes in the energy of a system and its surroundings. When considering the energy of a system, we use the concept of internal energy and how heat and work are related to it.

Internal energy, U, is the total energy (both kinetic and potential) in a system, including *translational kinetic energy* of molecules, the energy associated with molecular rotations and vibrations, the energy stored in chemical bonds and intermolecular attractions, and the energy associated with electrons in atoms. Some of these forms of internal energy are illustrated in Figure 7-9. Internal energy also includes energy associated with the interactions of protons and neutrons in atomic nuclei, although this component is unchanged in chemical reactions. A system contains *only* internal energy. A system does not contain energy in the form of heat or work. Heat and work are the means by which a system exchanges energy with its surroundings. *Heat and work exist only during a change in the system.* The relationship between heat (q), work (w), and changes in internal energy (ΔU) is dictated by the law of conservation of energy, expressed in the form known as the **first law of thermodynamics**.

$$\Delta U = q + w \qquad \textbf{(7.12)}$$

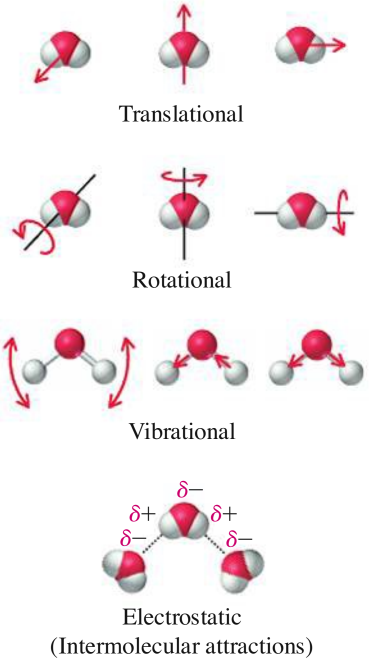
An isolated system is unable to exchange either heat or work with its surroundings, so that $\Delta U_{\text{isolated system}} = 0$, and we can say

The energy of an isolated system is constant.

In using equation (7.12) we must keep these important points in mind.

- Any energy *entering* the system carries a *positive* sign. Thus, if heat is *absorbed* by the system, $q > 0$. If work is done *on* the system, $w > 0$.
- Any energy *leaving* the system carries a *negative* sign. Thus, if heat is *given off* by the system, $q < 0$. If work is done *by* the system, $w < 0$.
- In general, the internal energy of a system changes as a result of energy entering or leaving the system as heat and/or work. If, on balance, more energy enters the system than leaves, ΔU is *positive*. If more energy leaves than enters, ΔU is *negative*.
- A consequence of $\Delta U_{\text{isolated system}} = 0$ is that $\Delta U_{\text{system}} = -\Delta U_{\text{surroundings}}$; that is, energy is conserved.

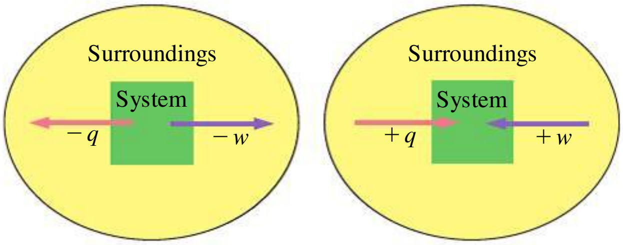
These ideas are summarized in Figure 7-10 and illustrated in Example 7-6.



▲ FIGURE 7-9
Some contributions to the internal energy of a system
The models represent water molecules, and the arrows represent the types of motion they can undergo. In the intermolecular attractions between water molecules, the symbols δ+ and δ− signify a separation of charge, producing centers of positive and negative charge that are smaller than ionic charges. These intermolecular attractions are discussed in Chapter 12.

KEEP IN MIND

that heat is the disordered flow of energy and work is the ordered flow of energy.



◀ FIGURE 7-10
Illustration of sign conventions used in thermodynamics
Arrows represent the direction of heat flow (→) and work (→). In the left diagram, the minus (−) signs signify energy leaving the system and entering the surroundings. In the right diagram the plus (+) signs refer to energy entering the system from the surroundings. These sign conventions are consistent with the expression $\Delta U = q + w$.

EXAMPLE 7-6 Relating ΔU, q, and w Through the First Law of Thermodynamics

A gas, while expanding (recall Figure 7-8), absorbs 25 J of heat and does 243 J of work. What is ΔU for the gas?

Analyze

The key to problems of this type lies in assigning the correct signs to the quantities of heat and work. Because heat is absorbed by (enters) the system, q is *positive*. Because work done *by* the system represents energy *leaving* the system, w is *negative*. You may find it useful to represent the values of q and w, with their correct signs, within parentheses. Then complete the algebra.

Solve

$$\Delta U = q + w = (+25\text{ J}) + (-243\text{ J}) = 25\text{ J} - 243\text{ J} = -218\text{ J}$$

Assess

The negative sign for the change in internal energy, ΔU, signifies that the system, in this case the gas, has lost energy.

PRACTICE EXAMPLE A: In compressing a gas, 355 J of work is done on the system. At the same time, 185 J of heat escapes from the system. What is ΔU for the system?

PRACTICE EXAMPLE B: If the internal energy of a system *decreases* by 125 J at the same time that the system *absorbs* 54 J of heat, does the system do work or have work done on it? How much?

7-6 CONCEPT ASSESSMENT

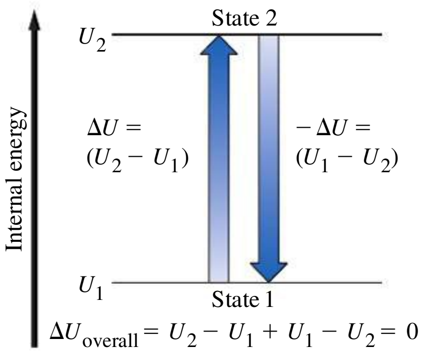
When water is injected into a balloon filled with ammonia gas, the balloon shrinks and feels warm. What are the sources of heat and work, and what are the signs of q and w in this process?

Functions of State

To describe a system completely, we must indicate its temperature, its pressure, and the kinds and amounts of substances present. When we have done this, we have specified the *state* of the system. Any property that has a unique value for a specified state of a system is said to be a **function of state**, or a **state function**. For example, a sample of pure water at 20 °C (293.15 K) and under a pressure of 100 kPa is in a specified state. The density of water in this state is 0.99820 g/mL. We can establish that this density is a unique value—a function of state—in the following way: Obtain three different samples of water—one purified by extensive distillation of groundwater; one synthesized by burning pure $H_2(g)$ in pure $O_2(g)$; and one prepared by driving off the water of hydration from $CuSO_4 \cdot 5\,H_2O$ and condensing the gaseous water to a liquid. The densities of the three different samples for the state that we specified will all be the same: 0.99820 g/mL. Thus, the value of a function of state depends on the state of the system, and not on how that state was established.

The internal energy of a system is a function of state, although there is no simple measurement or calculation that we can use to establish its value. That is, we cannot write down a value of U for a system in the same way that we can write $d = 0.99820$ g/mL for the density of water at 20 °C. Fortunately, we don't need to know actual values of U. Consider, for example, heating 10.0 g of ice at 0 °C to a final temperature of 50 °C. The internal energy of the ice at 0 °C has one unique value, U_1, while that of the liquid water at 50 °C has another, U_2. The *difference* in internal energy between these two states also has a unique value, $\Delta U = U_2 - U_1$, and this difference *is* something that we can precisely measure. It is the quantity of energy (as heat) that must be transferred from the surroundings to the system during the change from state 1 to state 2. As a further illustration, consider the scheme outlined here and illustrated by the diagram on page 257. Imagine that a system changes from state 1 to state 2 and then back to state 1.

$$\text{State 1 } (U_1) \xrightarrow{\Delta U} \text{State 2 } (U_2) \xrightarrow{-\Delta U} \text{State 1 } (U_1)$$



State 2
U_2
Internal energy
$\Delta U = (U_2 - U_1)$
$-\Delta U = (U_1 - U_2)$
U_1
State 1
$\Delta U_{overall} = U_2 - U_1 + U_1 - U_2 = 0$

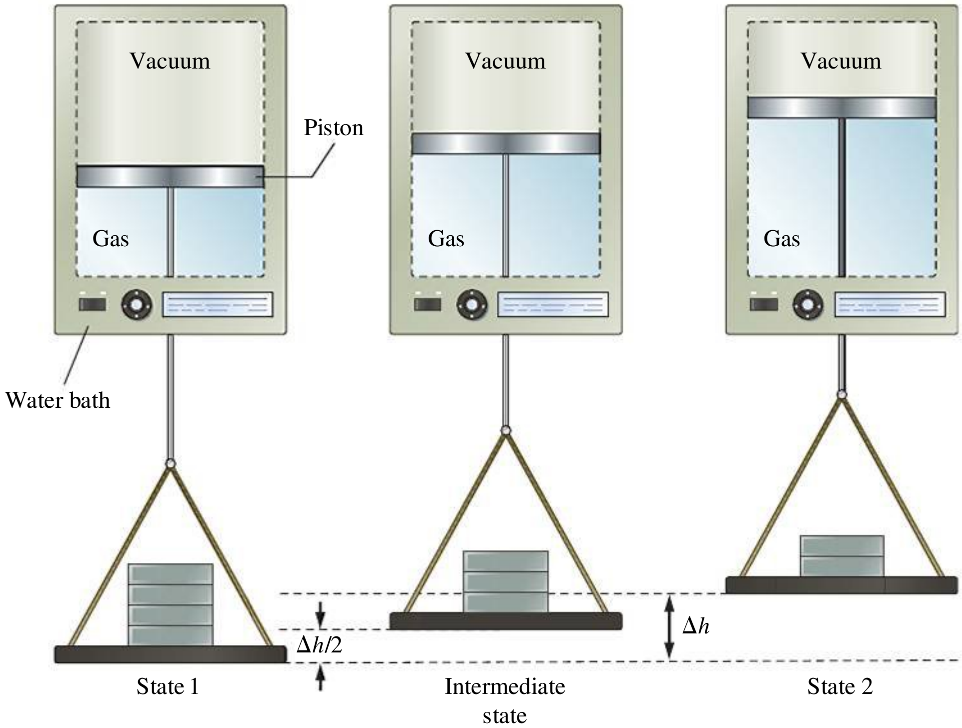
Because U has a unique value in each state, ΔU also has a unique value; it is $U_2 - U_1$. The change in internal energy when the system is returned from state 2 to state 1 is $-\Delta U = U_1 - U_2$. Thus, the *overall* change in internal energy is

$$\Delta U + (-\Delta U) = (U_2 - U_1) + (U_1 - U_2) = 0$$

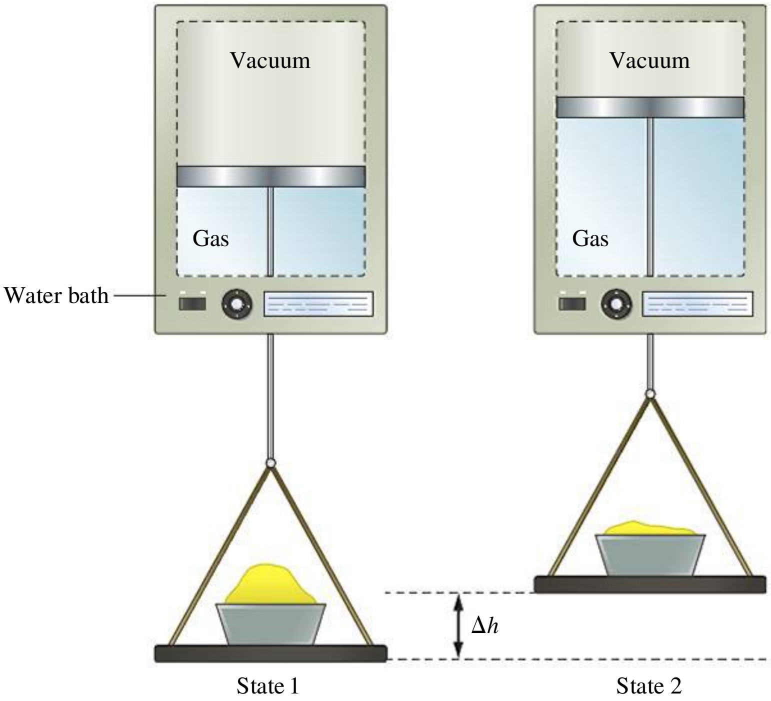
This means that the internal energy returns to its initial value of U_1, which it must do, since it is a function of state. It is important to note here that when we reverse the direction of change, we change the sign of ΔU.

Path-Dependent Functions

Unlike internal energy and changes in internal energy, heat (q) and work (w) are *not* functions of state. Their values depend on the path followed when a system undergoes a change. We can see why this is so by considering again the process described by Figure 7-8 and Example 7-5. Think of the 0.100 mol of He at 298 K and under a pressure of 2.40 atm as *state 1*, and under a pressure of 1.20 atm as *state 2*. The change from state 1 to state 2 occurred in a single step. Suppose that in another instance, we allowed the expansion to occur through an intermediate stage pictured in Figure 7-11. That is, suppose the external pressure on the gas was first reduced from 2.40 atm to 1.80 atm (at which point, the gas volume would be 1.36 L). Then, in a second stage, reduced from 1.80 atm to 1.20 atm, thereby arriving at state 2.



◀ FIGURE 7-11
A two-step expansion for the gas shown in Figure 7-8
In the initial state there are four weights of mass $M/2$ holding the gas back. In the intermediate state one of these weights has been removed and in the final state a second weight of mass $M/2$ has been removed. The initial and final states in this figure are the same as in Figure 7-8. This two-step expansion helps us to establish that the work of expansion depends on the path taken.



▶ FIGURE 7-12
A different method of achieving the expansion of a gas
In this expansion process, the weights in Figures 7-8 and 7-11 have been replaced by a pan containing sand, which has a mass of 2*M*, equivalent to that of the weights in the initial state. In the final state the mass of the sand has been reduced to *M*.

We calculated the amount of work done by the gas in a single-stage expansion in Example 7-5; it was $w = -1.24 \times 10^2$ J. The amount of work done in the two-stage process is the sum of two terms: the pressure–volume work for each stage of the expansion.

$$\begin{aligned} w &= -1.80\,\text{atm} \times (1.36\,\text{L} - 1.02\,\text{L}) - 1.20\,\text{atm} \times (2.04\,\text{L} - 1.36\,\text{L}) \\ &= -0.61\,\text{L atm} - 0.82\,\text{L atm} \\ &= -1.43\,\text{L atm} \times \frac{101\,\text{J}}{1\,\text{L atm}} = -1.44 \times 10^2\,\text{J} \end{aligned}$$

KEEP IN MIND

that if w differs in the two expansion processes, q must also differ, and in such a way that $q + w = \Delta U$ has a unique value, as required by the first law of thermodynamics.

The value of ΔU is the same for the single- and two-stage expansion processes because internal energy is a function of state. However, we see that slightly more work is done in the two-stage expansion. Work is not a function of state; it is path dependent. In the next section, we will stress that heat is also path dependent.

Now consider a different way to carry out the expansion from state 1 to state 2 (see Figure 7-12). The weights in Figures 7-8 and 7-11 have now been replaced by an equivalent amount of sand so that the gas is in state 1. Imagine sand is removed very slowly from this pile—say, one grain at a time. When exactly half the sand has been removed, the gas will have reached state 2. This very slow expansion proceeds in a nearly reversible fashion. A **reversible process** is one that can be made to reverse its direction when an infinitesimal change is made in a system variable. For example, adding a grain of sand rather than removing one would reverse the expansion we are describing. However, the process is not quite reversible because grains of sand have more than an infinitesimal mass. In this approximately reversible process we have made a very large number of intermediate expansions. This process provides more work than when the gas expands directly from state 1 to state 2.

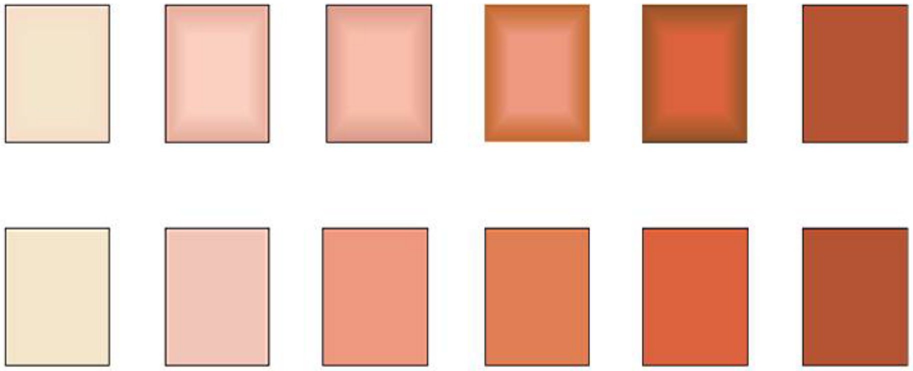
The important difference between the expansion in a finite number of steps and the reversible expansion is that the gas in the reversible process is always in equilibrium with its surroundings whereas in a stepwise process this is never the case. The stepwise processes are said to be **irreversible** because the system is not in equilibrium with the surroundings, and the process cannot be reversed by an infinitesimal change in a system variable.

In comparing the quantity of work done in the two different expansions (Figs. 7-8 and 7-11), we found them to be different, thereby proving that work is not a state function. Additionally, the quantity of work performed is greater in the two-step expansion (Fig. 7-11) than in the single-step expansion (Fig. 7-8). We leave it to the interested student to demonstrate, through Feature Problem 125, that the maximum possible work is that done in a reversible expansion (Fig. 7-12).

7-7 CONCEPT ASSESSMENT

A sample can be heated very slowly or very rapidly. The darker shading in the illustration indicates a higher temperature. Which of the two sets of diagrams do you think corresponds to reversible heating and which to spontaneous, or irreversible, heating?

◀ Although no perfectly reversible process exists, the melting and freezing of a substance at its transition temperature is an example of a process that is nearly reversible: pump in heat (melts), take out heat (freezes).



7-6 Heats of Reaction: ΔU and ΔH

Think of the reactants in a chemical reaction as the initial state of a system and the products as the final state.

$$\underset{\substack{\text{(initial state)}\\ U_i}}{\text{reactants}} \longrightarrow \underset{\substack{\text{(final state)}\\ U_f}}{\text{products}}$$

$$\Delta U = U_f - U_i$$

According to the first law of thermodynamics, we can also say that $\Delta U = q + w$. We have previously identified a heat of reaction as q_{rxn}, and so we can write

$$\Delta U = q_{rxn} + w$$

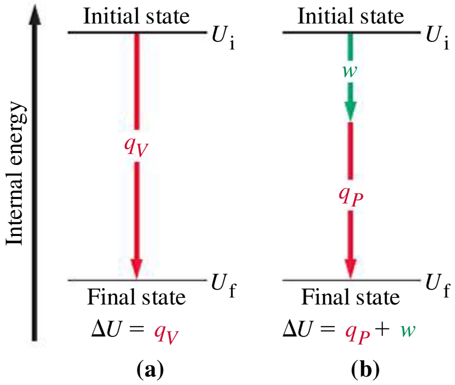
Now consider again a combustion reaction carried out in a bomb calorimeter (see Figure 7-5). The original reactants and products are confined within the bomb, and we say that the reaction occurs at *constant volume*. Because the volume is constant, $\Delta V = 0$, and no work is done. That is, $w = -P\Delta V = 0$. Denoting the heat of reaction for a constant-volume reaction as q_V, we see that $\Delta U = q_V$.

$$\Delta U = q_{rxn} + w = q_{rxn} + 0 = q_{rxn} = q_V \qquad \textbf{(7.13)}$$

The heat of reaction measured in a bomb calorimeter is equal to ΔU.

Chemical reactions are not ordinarily carried out in bomb calorimeters. The metabolism of sucrose occurs under the conditions present in the human body. The combustion of methane (natural gas) in a water heater occurs in an open flame. This question then arises: How does the heat of a reaction measured in a

▶ FIGURE 7-13
Two different paths leading to the same internal energy change in a system
In path **(a)**, the volume of the system remains constant and no internal energy is converted into work—think of burning gasoline in a bomb calorimeter. In path **(b)**, the system does work, so some of the internal energy change is used to do work—think of burning gasoline in an automobile engine to produce heat and work.



bomb calorimeter compare with the heat of reaction if the reaction is carried out in some other way? The usual other way is in beakers, flasks, and other containers open to the atmosphere and under the *constant pressure* of the atmosphere. We live in a world of constant pressure! The neutralization reaction of Example 7-4 is typical of this more common method of conducting chemical reactions.

In many reactions carried out at constant pressure, a small amount of pressure–volume work is done as the system expands or contracts (recall Figure 7-7). In these cases, the heat of reaction, q_P, is different from q_V. We know that the change in internal energy (ΔU) for a reaction carried out between a given initial and a given final state has a unique value. Furthermore, for a reaction at constant volume, $\Delta U = q_V$. From Figure 7-13 and the first law of thermodynamics, we see that for the same reaction at constant pressure $\Delta U = q_P + w$, which means $\Delta U = q_V = q_P + w$. Thus, unless $w = 0$, q_V and q_P must be different. The fact that q_V and q_P for a reaction may differ, even though ΔU has the same value, underscores that U is a function of state and q and w are not.

The relationship between q_V and q_P can be used to devise another state function that represents the heat flow for a process at constant pressure. To do this, we begin by writing

$$q_V = q_P + w$$

Now, using $\Delta U = q_V$, $w = -P\Delta V$ and rearranging terms, we obtain

$$\Delta U = q_P - P\Delta V$$
$$q_P = \Delta U + P\Delta V$$

The quantities U, P, and V are all state functions, so it should be possible to derive the expression $\Delta U + P\Delta V$ from yet another state function. This state function, called **enthalpy**, ***H***, is the sum of the internal energy and the pressure–volume product of a system: $H = U + PV$. The **enthalpy change**, ΔH, for a process between initial and final states is

$$\Delta H = H_f - H_i = (U_f + P_fV_f) - (U_i + P_iV_i)$$
$$\Delta H = (U_f - U_i) + (P_fV_f - P_iV_i)$$
$$\Delta H = \Delta U + \Delta PV$$

If the process is carried out at a constant temperature and pressure $(P_i = P_f)$ and with work limited to pressure–volume work, the enthalpy change is

$$\Delta H = \Delta U + P\Delta V$$

and the heat flow for the process under these conditions is

$$\Delta H = q_P \tag{7.14}$$

7-8 CONCEPT ASSESSMENT

Suppose a system is subjected to the following changes: a 40 kJ quantity of heat is added and the system does 15 kJ of work; then the system is returned to its original state by cooling and compression. What is the value of ΔH?

Enthalpy (ΔH) and Internal Energy (ΔU) Changes in a Chemical Reaction

We have noted that the heat of reaction at constant pressure, ΔH, and the heat of reaction at constant volume, ΔU, are related by the expression

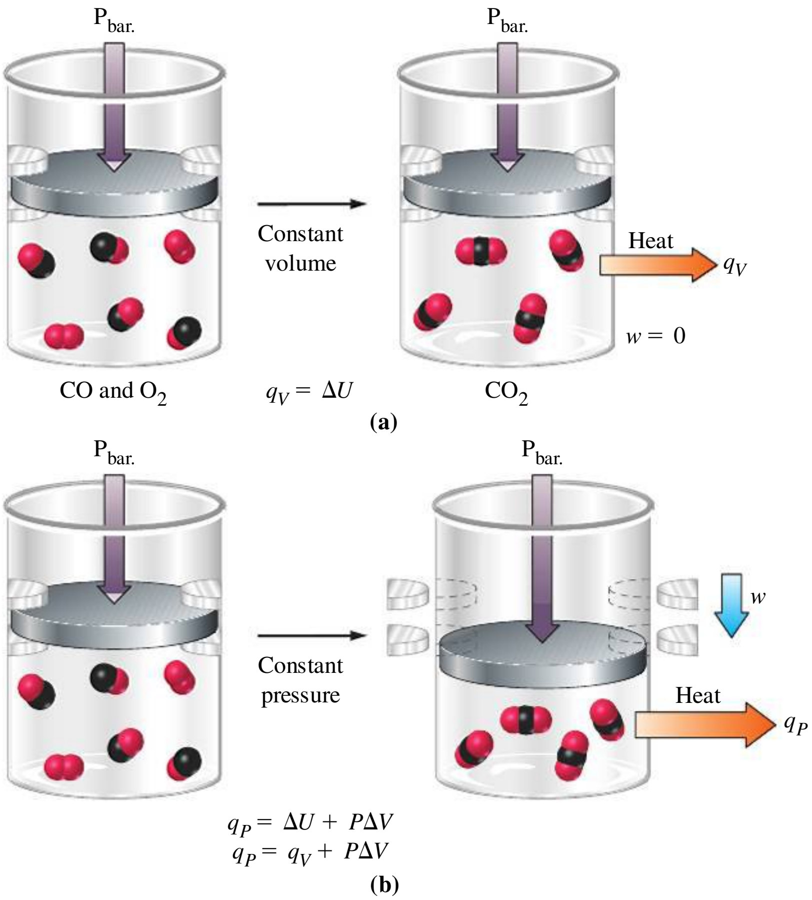
$$\Delta U = \Delta H - P\Delta V \qquad \textbf{(7.15)}$$

The last term in this expression is the energy associated with the change in volume of the system under a constant external pressure. To assess just how significant pressure–volume work is, consider the following reaction, which is also illustrated in Figure 7-14.

$$2\,\mathrm{CO(g)} + \mathrm{O_2(g)} \longrightarrow 2\,\mathrm{CO_2(g)}$$

If the heat of this reaction is measured under constant-pressure conditions at a constant temperature of 298 K, we get −566.0 kJ, indicating that 566.0 kJ of energy has left the system as heat: $\Delta H = -566.0$ kJ. To evaluate the pressure–volume work, we begin by writing

$$P\Delta V = P(V_f - V_i)$$



◀ FIGURE 7-14
Comparing heats of reaction at constant volume and constant pressure for the reaction $2\,\mathrm{CO(g)} + \mathrm{O_2(g)} \longrightarrow 2\,\mathrm{CO_2(g)}$
(a) No work is performed at constant volume because the piston cannot move because of the stops placed through the cylinder walls; $q_V = \Delta U = -563.5$ kJ. **(b)** When the reaction is carried out at constant pressure, the stops are removed. This allows the piston to move and the surroundings do work on the system, causing it to shrink into a smaller volume. More heat is evolved than in the constant-volume reaction; $q_p = \Delta H = -566.0$ kJ.

Then we can use the ideal gas equation to write this alternative expression.

$$P\Delta V = RT(n_f - n_i)$$

Here, n_f is the number of moles of gas in the products (2 mol CO_2) and n_i is the number of moles of gas in the reactants ($2\text{ mol CO} + 1\text{ mol O}_2$). Thus,

$$P\Delta V = 0.0083145\text{ kJ mol}^{-1}\text{ K}^{-1} \times 298\text{ K} \times [2 - (2 + 1)]\text{ mol} = -2.5\text{ kJ}$$

The change in internal energy is

$$\begin{aligned}\Delta U &= \Delta H - P\Delta V \\ &= -566.0\text{ kJ} - (-2.5\text{ kJ}) \\ &= -563.5\text{ kJ}\end{aligned}$$

This calculation shows that the $P\Delta V$ term is quite small compared to ΔH and that ΔU and ΔH are almost the same. An additional interesting fact here is that the volume of the system decreases as a consequence of the work done on the system by the surroundings.

In the combustion of sucrose at a fixed temperature, the heat of combustion turns out to be the same, whether at constant volume (q_V) or constant pressure (q_P). Only heat is transferred between the reaction mixture and the surroundings; no pressure–volume work is done. This is because the volume of a system is almost entirely determined by the volume of gas and because $12\text{ mol CO}_2(g)$ occupies the same volume as $12\text{ mol O}_2(g)$. There is no change in volume in the combustion of sucrose: $q_P = q_V$. Thus, the result of Example 7-3 can be represented as

$$C_{12}H_{22}O_{11}(s) + 12\,O_2(g) \longrightarrow 12\,CO_2(g) + 11\,H_2O(l) \quad \Delta H = -5.65 \times 10^3\text{ kJ} \quad \textbf{(7.16)}$$

That is, $1\text{ mol C}_{12}H_{22}O_{11}(s)$ reacts with $12\text{ mol O}_2(g)$ to produce $12\text{ mol CO}_2(g)$, $11\text{ mol H}_2O(l)$, and 5.65×10^3 kJ of evolved heat. Strictly speaking, the unit for ΔH should be kilojoules per mole, meaning per mole of reaction. "One mole of reaction" relates to the amounts of reactants and products in the equation as written. Thus, reaction (7.16) involves $1\text{ mol C}_{12}H_{22}O_{11}(s)$, $12\text{ mol O}_2(g)$, $12\text{ mol CO}_2(g)$, $11\text{ mol H}_2O(l)$, and -5.65×10^3 kJ of enthalpy change *per mol reaction*. The mol^{-1} part of the unit of ΔH is often dropped, but there are times we need to carry it to achieve the proper cancellation of units. We will find this to be the case in Chapters 19 and 20.

In summary, in most reactions, the heat of reaction we measure is ΔH. In some reactions, notably combustion reactions, we measure ΔU (that is, q_V). In reaction (7.16), $\Delta U = \Delta H$, but this is not always the case. Where it is not, a value of ΔH can be obtained from ΔU by the method illustrated in the discussion of expression (7.15), but even in those cases, ΔH and ΔU will be nearly equal. In this text, all heats of reactions are treated as ΔH values unless there is an indication to the contrary.

Example 7-7 shows how enthalpy changes can provide conversion factors for problem solving.

You may be wondering why the term ΔH is used instead of ΔU, q, and w. It's mainly a matter of convenience. Think of an analogous situation from daily life—buying gasoline at a gas station. The gasoline price posted on the pump is actually the sum of a base price and various taxes that must be paid to different levels of government. This breakdown is important to the accountants who must determine how much tax is to be paid to which agencies. To the consumer, however, it's easier to be given just the total cost per gallon or liter. After all, this determines what he or she must pay. In thermochemistry, our chief interest is generally in heats of reaction, not pressure–volume work. And because most reactions are carried out under atmospheric pressure, it's

EXAMPLE 7-7 Stoichiometric Calculations Involving Quantities of Heat

How much heat is associated with the complete combustion of 1.00 kg of sucrose, $C_{12}H_{22}O_{11}$?

Analyze

Equation (7.16) represents the combustion of 1 mol of sucrose. In that reaction the amount of heat generated is given as $\Delta H = -5.65 \times 10^3$ kJ/mol. The first step is to determine the number of moles in 1.00 kg of sucrose, and then use that value with the change in enthalpy for the reaction.

Solve

Express the quantity of sucrose in moles.

$$? \text{ mol} = 1.00 \text{ kg } C_{12}H_{22}O_{11} \times \frac{1000 \text{ g } C_{12}H_{22}O_{11}}{1 \text{ kg } C_{12}H_{22}O_{11}} \times \frac{1 \text{ mol } C_{12}H_{22}O_{11}}{342.3 \text{ g } C_{12}H_{22}O_{11}} = 2.92 \text{ mol } C_{12}H_{22}O_{11}$$

Formulate a conversion factor (shown in blue) based on the information in equation (7.16)—that is, -5.65×10^3 kJ of heat is associated with the combustion of 1 mol $C_{12}H_{22}O_{11}$.

$$? \text{ kJ} = 2.92 \text{ mol } C_{12}H_{22}O_{11} \times \frac{-5.65 \times 10^3 \text{ kJ}}{1 \text{ mol } C_{12}H_{22}O_{11}} = -1.65 \times 10^4 \text{ kJ}$$

The negative sign denotes that heat is given off in the combustion.

Assess

As discussed on page 249, the heat produced by a combustion reaction is not immediately transferred to the surroundings. Use data from Table 7.1 to show that the heat released by this reaction is *more* than that required to raise the temperature of the products to 100 °C.

PRACTICE EXAMPLE A: What mass of sucrose must be burned to produce 1.00×10^3 kJ of heat?

PRACTICE EXAMPLE B: A 25.0 mL sample of 0.1045 M HCl(aq) was neutralized by NaOH(aq). Use the result of Example 7-4 to determine the heat evolved in this neutralization.

helpful to have a function of state, enthalpy, H, whose change is exactly equal to something we can measure: q_P.

Enthalpy Change (ΔH) Accompanying a Change in State of Matter

When a liquid is in contact with the atmosphere, energetic molecules at the surface of the liquid can overcome forces of attraction to their neighbors and pass into the gaseous, or vapor, state. We say that the liquid *vaporizes*. If the temperature of the liquid is to remain constant, the liquid must absorb heat from its surroundings to replace the energy carried off by the vaporizing molecules. The heat required to vaporize a fixed quantity of liquid is called the enthalpy (or heat) of vaporization. Usually the fixed quantity of liquid chosen is one mole, and we can call this quantity the *molar enthalpy o fvaporization*. For example,

$$H_2O(l) \longrightarrow H_2O(g) \qquad \Delta H = 44.0 \text{ kJ at } 298 \text{ K}$$

We described the melting of a solid in a similar fashion (page 244). The energy requirement in this case is called the enthalpy (or heat) of fusion. For the melting of one mole of ice, we can write

$$H_2O(s) \longrightarrow H_2O(l) \qquad \Delta H = 6.01 \text{ kJ at } 273.15 \text{ K}$$

We can use the data represented in these equations, together with other appropriate data, to answer questions like those posed in Example 7-8 and its accompanying Practice Examples.

EXAMPLE 7-8 Enthalpy Changes Accompanying Changes in States of Matter

Calculate ΔH for the process in which 50.0 g of water is converted from liquid at 10.0 °C to vapor at 25.0 °C.

Analyze

The key to this calculation is to view the process as proceeding in two steps: first raising the temperature of liquid water from 10.0 to 25.0 °C, and then completely vaporizing the liquid at 25.0 °C. The total enthalpy change is the sum of the changes in the two steps. For a process at constant pressure, $\Delta H = q_P$, so we need to calculate the heat absorbed in each step.

Solve

HEATING WATER FROM 10.0 TO 25.0°C

This heat requirement can be determined by the method shown in Example 7-1; that is, we apply equation (7.5).

$$? \text{ kJ} = 50.0 \text{ g H}_2\text{O} \times \frac{4.18 \text{ J}}{\text{g H}_2\text{O }°\text{C}} \times (25.0 - 10.0)\ °\text{C} \times \frac{1 \text{ kJ}}{1000 \text{ J}} = 3.14 \text{ kJ}$$

VAPORIZING WATER AT 25.0°C

For this part of the calculation, the quantity of water must be expressed in moles so that we can then use the molar enthalpy of vaporization at 25 °C: 44.0 kJ/mol.

$$? \text{ kJ} = 50.0 \text{ g H}_2\text{O} \times \frac{1 \text{ mol H}_2\text{O}}{18.02 \text{ g H}_2\text{O}} \times \frac{44.0 \text{ kJ}}{1 \text{ mol H}_2\text{O}} = 122 \text{ kJ}$$

TOTAL ENTHALPY CHANGE

$$\Delta H = 3.14 \text{ kJ} + 122 \text{ kJ} = 125 \text{ kJ}$$

Assess

Note that the enthalpy change is positive, which reflects that the system (i.e., the water) gains energy. The reverse would be true for condensation of water at 25.0 °C and cooling it to 10.0 °C.

PRACTICE EXAMPLE A: What is the enthalpy change when a cube of ice 2.00 cm on edge is brought from −10.0 °C to a final temperature of 23.2 °C? For ice, use a density of 0.917 g/cm^3, a specific heat of 2.01 $\text{J g}^{-1}\ °\text{C}^{-1}$, and an enthalpy of fusion of 6.01 kJ/mol.

PRACTICE EXAMPLE B: What is the maximum mass of ice at −15.0 °C that can be completely converted to water vapor at 25.0 °C if the available heat for this transition is 5.00×10^3 kJ?

Standard States and Standard Enthalpy Changes

The measured enthalpy change for a reaction has a unique value *only* if the initial state (reactants) and final state (products) are precisely described. If we define a particular state as *standard* for the reactants and products, we can then say that the standard enthalpy change is the enthalpy change in a reaction in which the reactants and products are in their standard states. This so-called **standard enthalpy of reaction** is denoted with a degree symbol, $\mathbf{\Delta H°}$.

The **standard state** of a solid or liquid substance is the pure element or compound at a pressure of *1 bar* (10^5 Pa)* and at the temperature of interest. For a gas, the standard state is the pure gas behaving as an (hypothetical) ideal gas at a pressure of 1 bar and the temperature of interest. Although temperature is not part of the definition of a standard state, it still must be specified in tabulated values of $\Delta H°$, because $\Delta H°$ depends on temperature. The values given in this text are all for 298.15 K (25 °C) unless otherwise stated.

---

*The International Union of Pure and Applied Chemistry (IUPAC) recommended that the standard-state pressure be changed from 1 atm to 1 bar about 25 years ago, but some data tables are still based on the 1 atm standard. Fortunately, the differences in values resulting from this change in standard-state pressure are very small—almost always small enough to be ignored.

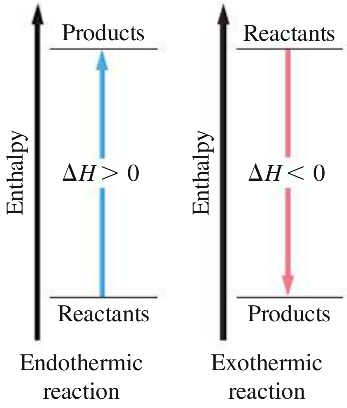
In the rest of this chapter, we will mostly use standard enthalpy changes. We will explore the details of nonstandard conditions in Chapter 19.

Enthalpy Diagrams

The negative sign of ΔH in equation (7.16) means that the enthalpy of the products is lower than that of the reactants. This *decrease* in enthalpy appears as heat evolved to the surroundings. The combustion of sucrose is an exothermic reaction. In the reaction

$$N_2(g) + O_2(g) \longrightarrow 2\,NO(g) \qquad \Delta H^\circ = 180.50\ \text{kJ} \tag{7.17}$$

the products have a *higher* enthalpy than the reactants; ΔH is positive. To produce this increase in enthalpy, heat is absorbed from the surroundings. The reaction is endothermic. An **enthalpy diagram** is a diagrammatic representation of enthalpy changes in a process. Figure 7-15 shows how exothermic and endothermic reactions can be represented through such diagrams.

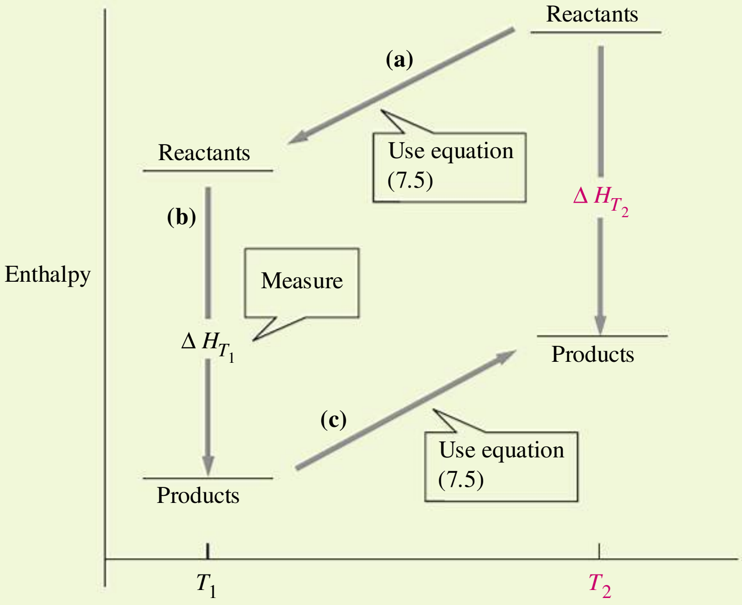


▲ FIGURE 7-15
Enthalpy diagrams
Horizontal lines represent absolute values of enthalpy. The higher a horizontal line, the greater the value of H that it represents. Vertical lines or arrows represent changes in enthalpy (ΔH). Arrows pointing up signify increases in enthalpy—endothermic reactions. Arrows pointing down signify decreases in enthalpy—exothermic reactions.

7-1 ARE YOU WONDERING...

Why ΔH depends on temperature?

The difference in ΔH for a reaction at two different temperatures is determined by the amount of heat involved in changing the reactants and products from one temperature to the other under constant pressure. These quantities of heat can be calculated with the help of equation (7.5): q_P = heat capacity × temperature change = $C_P \times \Delta T$. We write an expression of this type for each reactant and product and combine these expressions with the measured ΔH value at one temperature to obtain the value of ΔH at another. This method is illustrated in Figure 7-16 and applied in Exercise 117.



▲ FIGURE 7-16
Conceptualizing ΔH as a function of temperature
In the three-step process outlined here, **(a)** the reactants are cooled from the temperature T_2 to T_1. **(b)** The reaction is carried out at T_1, and **(c)** the products are warmed from T_1 to T_2. When the quantities of heat associated with each step are combined, the result is the same as if the reaction had been carried out at T_2, that is, ΔH_{T_2}.

7-7 Indirect Determination of ΔH: Hess's Law

One of the reasons that the enthalpy concept is so useful is that a large number of heats of reaction can be calculated from a small number of measurements. The following features of enthalpy change (ΔH) make this possible.

- **ΔH Is an Extensive Property.** Consider the standard enthalpy change in the formation of NO(g) from its elements at 25 °C.

$$N_2(g) + O_2(g) \longrightarrow 2\,NO(g) \qquad \Delta H^\circ = 180.50\ \text{kJ}$$

To express the enthalpy change in terms of *one mole* of NO(g), we divide all coefficients *and the ΔH value* by *two*.

$$\frac{1}{2}N_2(g) + \frac{1}{2}O_2(g) \longrightarrow NO(g) \qquad \Delta H^\circ = \frac{1}{2} \times 180.50 = 90.25\ \text{kJ}$$

Enthalpy change is directly proportional to the amounts of substances in a system.

▶ Although we have avoided fractional coefficients previously, we need them here. The coefficient of NO(g) must be one.

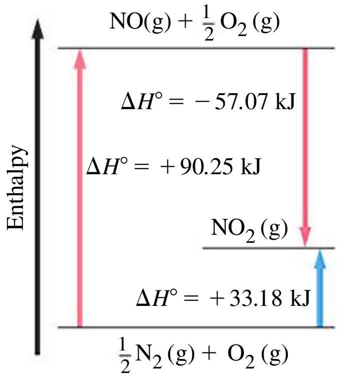
- **ΔH Changes Sign When a Process Is Reversed.** As we learned on page 257, if a process is reversed, the change in a function of state reverses sign. Thus, ΔH for the *decomposition* of one mole of NO(g) is $-\Delta H$ for the *formation* of one mole of NO(g).

$$NO(g) \longrightarrow \frac{1}{2}N_2(g) + \frac{1}{2}O_2(g) \qquad \Delta H^\circ = -90.25\ \text{kJ}$$

- **Hess's Law of Constant Heat Summation.** To describe the standard enthalpy change for the formation of $NO_2(g)$ from $N_2(g)$ and $O_2(g)$,

$$\frac{1}{2}N_2(g) + O_2(g) \longrightarrow NO_2(g) \qquad \Delta H^\circ = ?$$

we can think of the reaction as proceeding in two steps: First we form NO(g) from $N_2(g)$ and $O_2(g)$, and then $NO_2(g)$ from NO(g) and $O_2(g)$. When the equations for these two steps are added together in the manner suggested by the red arrows in Figure 7-17, we get the overall result represented by the blue arrow.



$NO(g) + \frac{1}{2}O_2(g)$
$\Delta H^\circ = -57.07$ kJ
$\Delta H^\circ = +90.25$ kJ
$NO_2(g)$
$\Delta H^\circ = +33.18$ kJ
$\frac{1}{2}N_2(g) + O_2(g)$
Enthalpy

▲ FIGURE 7-17
An enthalpy diagram illustrating Hess's law
Whether the reaction occurs through a single step (blue arrow) or in two steps (red arrows), the enthalpy change is $\Delta H^\circ = 33.18$ kJ for the overall reaction $\frac{1}{2}N_2(g) + O_2(g) \longrightarrow NO_2(g)$.

$$\begin{aligned}
\frac{1}{2}N_2(g) + O_2(g) &\longrightarrow \cancel{NO(g)} + \cancel{\frac{1}{2}O_2(g)} & \Delta H^\circ &= +90.25\ \text{kJ}\\
\cancel{NO(g)} + \cancel{\frac{1}{2}O_2(g)} &\longrightarrow NO_2(g) & \Delta H^\circ &= -57.07\ \text{kJ}\\
\hline
\frac{1}{2}N_2(g) + O_2(g) &\longrightarrow NO_2(g) & \Delta H^\circ &= +33.18\ \text{kJ}
\end{aligned}$$

Note that in summing the two equations NO(g), a species that would have appeared on both sides of the overall equation was canceled out. Also, because we used an enthalpy diagram, the superfluous term $^1/_2\,O_2(g)$ entered in and then canceled out. We have just introduced **Hess's law**, which states the following principle:

> If a process occurs in stages or steps (even if only hypothetically), the enthalpy change for the overall process is the sum of the enthalpy changes for the individual steps.

Hess's law is simply a consequence of the state function property of enthalpy. Regardless of the path taken in going from the initial state to the final state, ΔH (or ΔH° if the process is carried out under standard conditions) has the same value.

Suppose we want the standard enthalpy change for the reaction

$$3\,C(\text{graphite}) + 4\,H_2(g) \longrightarrow C_3H_8(g) \qquad \Delta H^\circ = ? \tag{7.18}$$

KEEP IN MIND

that ΔH° is an extensive property. In a chemical equation, the stoichiometric coefficients specify the amounts involved, and the unit kJ suffices for ΔH°. When ΔH° is not accompanied by an equation, the amount involved must somehow be specified, such as per mole of $C_3H_8(g)$ in the expression $\Delta H^\circ_{comb} = -2219.9\ \text{kJ/mol}\ C_3H_8(g)$.

How should we proceed? If we try to get graphite and hydrogen to react, a slight reaction will occur, but it will not go to completion. Furthermore, the product will not be limited to propane (C_3H_8); several other hydrocarbons will form as well. The fact is that we cannot directly measure $\Delta H°$ for reaction (7.18). Instead, we must resort to an *indirect calculation* from $\Delta H°$ values that can be established by experiment. Here is where Hess's law is of greatest value. It permits us to calculate ΔH values that we cannot measure directly. In Example 7-9,

EXAMPLE 7-9 Applying Hess's Law

Use the heat of combustion data from page 268 to determine $\Delta H°$ for reaction (7.18)

$$3\,C(\text{graphite}) + 4\,H_2(g) \longrightarrow C_3H_8(g) \qquad \Delta H° = ?$$

Analyze

To determine an enthalpy change with Hess's law, we need to combine the appropriate chemical equations. A good starting point is to write chemical equations for the given combustion reactions based on *one mole* of the indicated reactant. Recall (see page 114) that the products of the combustion of carbon–hydrogen–oxygen compounds are $CO_2(g)$ and $H_2O(l)$.

Solve

Begin by writing the following equations

$$\begin{array}{llll}
\textbf{(a)} & C_3H_8(g) + 5\,O_2(g) \longrightarrow 3\,CO_2(g) + 4\,H_2O(l) & \Delta H° = -2219.9\text{ kJ} \\
\textbf{(b)} & C(\text{graphite}) + O_2(g) \longrightarrow CO_2(g) & \Delta H° = -393.5\text{ kJ} \\
\textbf{(c)} & H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l) & \Delta H° = -285.8\text{ kJ}
\end{array}$$

Because our objective in reaction (7.18) is to *produce* $C_3H_8(g)$, the next step is to find a reaction in which $C_3H_8(g)$ is formed—the *reverse* of reaction **(a)**.

$$-\textbf{(a)}:\ 3\,CO_2(g) + 4\,H_2O(l) \longrightarrow C_3H_8(g) + 5\,O_2(g) \qquad \Delta H° = -(-2219.9)\text{ kJ} = +2219.9\text{ kJ}$$

Now, we turn our attention to the reactants, C(graphite) and $H_2(g)$. To get the proper number of moles of each, we must multiply equation **(b)** by three and equation **(c)** by four.

$$\begin{array}{lll}
3\times\textbf{(b)}: & 3\,C(\text{graphite}) + 3\,O_2(g) \longrightarrow 3\,CO_2(g) & \Delta H° = 3(-393.5\text{ kJ}) = -1181\text{ kJ} \\
4\times\textbf{(c)}: & 4\,H_2(g) + 2\,O_2(g) \longrightarrow 4\,H_2O(l) & \Delta H° = 4(-285.8\text{ kJ}) = -1143\text{ kJ}
\end{array}$$

Here is the overall change we have described: 3 mol C(graphite) and 4 mol $H_2(g)$ have been consumed, and 1 mol $C_3H_8(g)$ has been produced. This is exactly what is required in equation (7.18). We can now combine the three modified equations.

$$\begin{array}{lll}
-\textbf{(a)}: & 3\,\cancel{CO_2(g)} + 4\,\cancel{H_2O(l)} \longrightarrow C_3H_8(g) + 5\,\cancel{O_2(g)} & \Delta H° = +2219.9\text{ kJ} \\
3\times\textbf{(b)}: & 3\,C(\text{graphite}) + 3\,\cancel{O_2(g)} \longrightarrow 3\,\cancel{CO_2(g)} & \Delta H° = -1181\text{ kJ} \\
4\times\textbf{(c)}: & 4\,H_2(g) + 2\,\cancel{O_2(g)} \longrightarrow 4\,\cancel{H_2O(l)} & \Delta H° = -1143\text{ kJ} \\
\hline
 & 3\,C(\text{graphite}) + 4\,H_2(g) \longrightarrow C_3H_8(g) & \Delta H° = -104\text{ kJ}
\end{array}$$

Assess

Hess's law is a powerful technique to determine the enthalpy of reaction by using a series of unrelated reactions, along with their enthalpies of reaction. In this example, we took three unrelated combustion reactions and were able to determine the enthalpy of reaction of another reaction.

PRACTICE EXAMPLE A: The standard heat of combustion of propene, $C_3H_6(g)$, is -2058 kJ/mol $C_3H_6(g)$. Use this value and other data from this example to determine $\Delta H°$ for the hydrogenation of propene to propane.

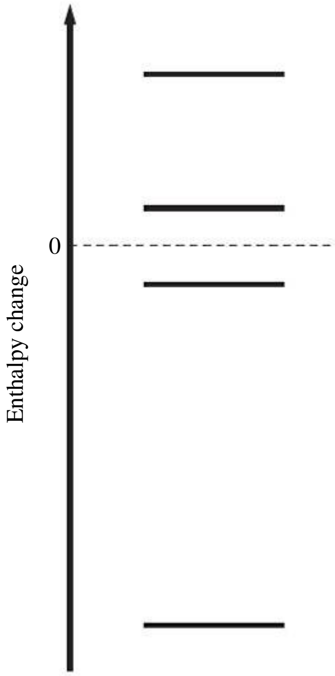
$$CH_3CH{=}CH_2(g) + H_2(g) \longrightarrow CH_3CH_2CH_3(g) \qquad \Delta H° = ?$$

PRACTICE EXAMPLE B: From the data in Practice Example 7-9A and the following equation, determine the standard enthalpy of combustion of one mole of 2-propanol, $CH_3CH(OH)CH_3(l)$.

$$CH_3CH{=}CH_2(g) + H_2O(l) \longrightarrow CH_3CH(OH)CH_3(l) \qquad \Delta H° = -52.3\text{ kJ}$$

we use the following standard heats of combustion $\Delta H^\circ_{\text{comb}}$ to calculate ΔH° for reaction (7.18).

$$\begin{aligned} \Delta H^\circ_{\text{comb}} \quad C_3H_8(g) &= -2219.9\ \text{kJ/mol}\ C_3H_8(g) \\ C(\text{graphite}) &= -393.5\ \text{kJ/mol}\ C(\text{graphite}) \\ H_2(g) &= -285.8\ \text{kJ/mol}\ H_2(g) \end{aligned}$$



7-9 CONCEPT ASSESSMENT

The heat of reaction between carbon (graphite) and the corresponding stoichiometric amounts of hydrogen gas to form $C_2H_2(g)$, $C_2H_4(g)$, and $C_2H_6(g)$ are 226.7, 52.3 and −84.7 kJ mol^{-1}, respectively. Relate these values to the enthalpy diagram shown in the margin. Indicate on the diagram the standard enthalpy change for the reaction $C_2H_2(g) + 2\,H_2(g) \longrightarrow C_2H_6(g)$.

7-8 Standard Enthalpies of Formation

In the enthalpy diagrams we have drawn, we have not written any numerical values on the enthalpy axis. This is because we cannot determine *absolute* values of enthalpy, H. However, enthalpy *is* a function of state, so *changes* in enthalpy, ΔH, have unique values. We can deal just with these changes. Nevertheless, as with many other properties, it is still useful to have a starting point, a zero value.

Consider a map-making analogy: What do we list as the height of a mountain? Do we mean by this the vertical distance between the mountaintop and the center of Earth? Between the mountaintop and the deepest trench in the ocean? No. By agreement, we mean the vertical distance between the mountaintop and mean sea level. We *arbitrarily* assign to mean sea level an elevation of zero, and all other points on Earth are relative to this zero elevation. The elevation of Mt. Everest is +8848 m; that of Badwater, Death Valley, California, is −86 m. We do something similar with enthalpies. We relate our zero to the enthalpies of certain forms of the elements and determine the enthalpies of other substances relative to this zero.

The **standard enthalpy of formation** (ΔH°_f) of a substance is the enthalpy *change* that occurs in the formation of one mole of the substance in the standard state from the *reference* forms of the elements in their standard states. The reference forms of the elements in all but a few cases are the most stable forms of the elements at one bar and the given temperature. The degree symbol denotes that the enthalpy change is a standard enthalpy change, and the subscript "f" signifies that the reaction is one in which a substance is formed from its elements. Because the formation of the most stable form of an element from itself is no change at all,

KEEP IN MIND

that we use the expression "standard enthalpy of formation" even though what we are describing is actually a standard enthalpy *change*.

the standard enthalpy of formation of a pure element in its reference form is 0.

Listed here are the most stable forms of several elements at 298.15 K, the temperature at which thermochemical data are commonly tabulated.

$$Na(s) \quad H_2(g) \quad N_2(g) \quad O_2(g) \quad C(\text{graphite}) \quad Br_2(l)$$

The situation with carbon is an interesting one. In addition to graphite, carbon also exists naturally in the form of diamond. However, because there is a measurable enthalpy difference between them, they cannot both be assigned $\Delta H^\circ_f = 0$.

$$C(\text{graphite}) \longrightarrow C(\text{diamond}) \qquad \Delta H^\circ = 1.9\ \text{kJ}$$

▲ Diamond and graphite.

We choose as the reference form the more stable form, the one with the lower enthalpy. Thus, we assign $\Delta H^\circ_f(\text{graphite}) = 0$, and $\Delta H^\circ_f(\text{diamond}) =$

1.9 kJ/mol. Although we can obtain bromine in either the gaseous or liquid state at 298.15 K, $Br_2(l)$ is the most stable form. $Br_2(g)$, if obtained at 298.15 K and 1 bar pressure, immediately condenses to $Br_2(l)$.

$$Br_2(l) \longrightarrow Br_2(g) \qquad \Delta H^\circ_f = 30.91\ \text{kJ}$$

The enthalpies of formation are $\Delta H^\circ_f[Br_2(l)] = 0$ and $\Delta H^\circ_f[Br_2(g)] = 30.91$ kJ/mol.

A rare case in which the reference form is not the most stable form is the element phosphorus. Although over time it converts to solid red phosphorus, solid white phosphorus has been chosen as the reference form.

$$P(s, \text{white}) \longrightarrow P(s, \text{red}) \qquad \Delta H^\circ_f = -17.6\ \text{kJ}$$

The standard enthalpies of formation are $\Delta H^\circ_f[P(s, \text{white})] = 0$ and $\Delta H^\circ_f[P(s, \text{red})] = -17.6$ kJ/mol.

Standard enthalpies of formation of some common substances are presented in Table 7.2. Figure 7-18 emphasizes that both positive and negative standard enthalpies of formation are possible. It also suggests that standard enthalpies of formation are related to molecular structure.

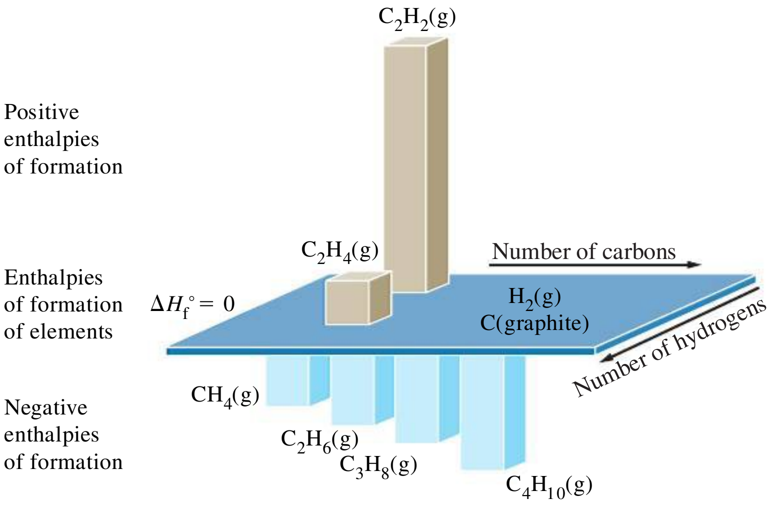
We will use standard enthalpies of formation in a variety of calculations. Often, the first thing we must do is write the chemical equation to which a ΔH°_f value applies, as in Example 7-10.

▲ Liquid bromine vaporizing.

TABLE 7.2 Some Standard Molar Enthalpies of Formation, ΔH°_f at 298.15 K

Substance	kJ/mol[a]	Substance	kJ/mol[a]
$CO(g)$	−110.5	$HBr(g)$	−36.40
$CO_2(g)$	−393.5	$HI(g)$	26.48
$CH_4(g)$	−74.81	$H_2O(g)$	−241.8
$C_2H_2(g)$	226.7	$H_2O(l)$	−285.8
$C_2H_4(g)$	52.26	$H_2S(g)$	−20.63
$C_2H_6(g)$	−84.68	$NH_3(g)$	−46.11
$C_3H_8(g)$	−103.8	$NO(g)$	90.25
$C_4H_{10}(g)$	−125.6	$N_2O(g)$	82.05
$CH_3OH(l)$	−238.7	$NO_2(g)$	33.18
$C_2H_5OH(l)$	−277.7	$N_2O_4(g)$	9.16
$HF(g)$	−271.1	$SO_2(g)$	−296.8
$HCl(g)$	−92.31	$SO_3(g)$	−395.7

[a] Values are for reactions in which one mole of substance is formed. Most of the data have been rounded off to four significant figures.



◀ FIGURE 7-18
Some standard enthalpies of formation at 298.15 K
Standard enthalpies of formation of elements are shown in the central plane, with $\Delta H^\circ_f = 0$. Substances with positive enthalpies of formation are above the plane, while those with negative enthalpies of formation are below the plane.

EXAMPLE 7-10 Relating a Standard Enthalpy of Formation to a Chemical Equation

The enthalpy of formation of formaldehyde is $\Delta H_f^\circ = -108.6$ kJ/mol HCHO(g) at 298 K. Write the chemical equation to which this value applies.

Analyze

The equation must be written for the formation of one mole of gaseous HCHO. The most stable forms of the elements at 298.15 K and 1 bar are gaseous H_2 and O_2 and solid carbon in the form of graphite (Fig. 7-19). Note that we need one fractional coefficient in this equation.

Solve

$$H_2(g) + \frac{1}{2}O_2(g) + C(\text{graphite}) \longrightarrow HCHO(g) \qquad \Delta H_f^\circ = -108.6\ \text{kJ}$$

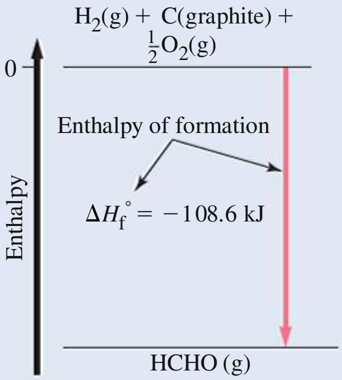
Assess

When answering these types of problems, we must remember to use the elements in their most stable form under the given conditions. In this example, the stated conditions were 298 K and 1 bar.

PRACTICE EXAMPLE A: The standard enthalpy of formation for the amino acid leucine is -637.3 kJ/mol $C_6H_{13}O_2N(s)$. Write the chemical equation to which this value applies.

PRACTICE EXAMPLE B: How is ΔH° for the following reaction related to the standard enthalpy of formation of $NH_3(g)$ listed in Table 7.2? What is the value of $\Delta H^\circ = ?$

$$2\,NH_3(g) \longrightarrow N_2(g) + 3\,H_2(g) \qquad \Delta H^\circ = ?$$



▲ FIGURE 7-19 **Standard enthalpy of formation of formaldehyde, HCHO(g)** The formation of HCHO(g) from its elements in their standard states is an exothermic reaction. The heat evolved per mole of HCHO(g) formed is the standard enthalpy (heat) of formation.

7-2 ARE YOU WONDERING...

What is the significance of the sign of a ΔH_f° value?

A compound having a positive value of ΔH_f° is formed from its elements by an endothermic reaction. If the reaction is reversed, the compound decomposes into its elements in an exothermic reaction. We say that the compound is unstable with respect to its elements. This does not mean that the compound cannot be made, but it does suggest a tendency for the compound to enter into chemical reactions yielding products with lower enthalpies of formation.

When no other criteria are available, chemists sometimes use enthalpy change as a rough indicator of the likelihood of a chemical reaction occurring—exothermic reactions generally being more likely to occur unassisted than endothermic ones. We'll present much better criteria later in the text.

Standard Enthalpies of Reaction

We have learned that if the reactants and products of a reaction are in their standard states, the enthalpy change is a *standard* enthalpy change, which we can denote as ΔH° or $\Delta H^\circ_{\text{rxn}}$. One of the primary uses of standard enthalpies of formation is in calculating standard enthalpies of reaction.

Let us use Hess's law to calculate the standard enthalpy of reaction for the decomposition of sodium bicarbonate, a minor reaction that occurs when baking soda is used in baking.

$$2\,NaHCO_3(s) \longrightarrow Na_2CO_3(s) + H_2O(l) + CO_2(g) \qquad \Delta H^\circ = ? \qquad \textbf{(7.19)}$$

From Hess's law, we see that the following four equations yield equation (7.19) when added together.

$$\textbf{(a)}\ 2\,\mathrm{NaHCO_3(s)} \longrightarrow 2\,\mathrm{Na(s)} + \mathrm{H_2(g)} + 2\,\mathrm{C(graphite)} + 3\,\mathrm{O_2(g)} \qquad \Delta H^\circ = -2 \times \Delta H_f^\circ[\mathrm{NaHCO_3(s)}]$$

$$\textbf{(b)}\ 2\,\mathrm{Na(s)} + \mathrm{C(graphite)} + \frac{3}{2}\mathrm{O_2(g)} \longrightarrow \mathrm{Na_2CO_3(s)} \qquad \Delta H^\circ = \Delta H_f^\circ[\mathrm{Na_2CO_3(s)}]$$

$$\textbf{(c)}\ \mathrm{H_2(g)} + \frac{1}{2}\mathrm{O_2(g)} \longrightarrow \mathrm{H_2O(l)} \qquad \Delta H^\circ = \Delta H_f^\circ[\mathrm{H_2O(l)}]$$

$$\textbf{(d)}\ \mathrm{C(graphite)} + \mathrm{O_2(g)} \longrightarrow \mathrm{CO_2(g)} \qquad \Delta H^\circ = \Delta H_f^\circ[\mathrm{CO_2(g)}]$$

$$\overline{\quad 2\,\mathrm{NaHCO_3(s)} \longrightarrow \mathrm{Na_2CO_3(s)} + \mathrm{H_2O(l)} + \mathrm{CO_2(g)} \qquad \Delta H^\circ = ?\quad}$$

Equation (a) is the *reverse* of the equation representing the formation of two moles of $[\mathrm{NaHCO_3(s)}]$ from its elements. This means that ΔH° for reaction (a) is the *negative* of twice $\Delta H_f^\circ[\mathrm{NaHCO_3(s)}]$. Equations (b), (c) and (d) represent the formation of *one* mole each of $\mathrm{Na_2CO_3(s)}$, $\mathrm{CO_2(g)}$ and $\mathrm{H_2O(l)}$. Thus, we can express the value of ΔH° for the decomposition reaction as

$$\Delta H^\circ = \Delta H_f^\circ[\mathrm{Na_2CO_3(s)}] + \Delta H_f^\circ[\mathrm{H_2O(l)}] + \Delta H_f^\circ[\mathrm{CO_2(g)}] - 2 \times \Delta H_f^\circ[\mathrm{NaHCO_3(s)}] \qquad \textbf{(7.20)}$$

We can use the enthalpy diagram in Figure 7-20 to visualize the Hess's law procedure and to show how the state function property of enthalpy enables us to arrive at equation (7.20). Imagine the decomposition of sodium bicarbonate taking place in two steps. In the first step, suppose a vessel contains 2 mol $\mathrm{NaHCO_3}$, which is allowed to decompose into 2 mol Na(s), 2 mol C(graphite), 1 mol $\mathrm{H_2(g)}$, and 3 mol $\mathrm{O_2(g)}$, as in equation (a) above. In the second step, recombine the 2 mol Na(s), 2 mol C(graphite), 1 mol $\mathrm{H_2(g)}$, and 3 mol $\mathrm{O_2(g)}$ to form the products according to equations (b), (c), and (d) above.

The pathway shown in Figure 7-20 *is not* how the reaction actually occurs. This does not matter, though, because enthalpy is a state function and the change of any state function is independent of the path chosen. The enthalpy change for the overall reaction is the sum of the standard enthalpy changes of the individual steps.

$$\begin{aligned} \Delta H^\circ &= \Delta H^\circ_{\text{decomposition}} + \Delta H^\circ_{\text{recombination}} \\ \Delta H^\circ_{\text{decomposition}} &= -2 \times \Delta H_f^\circ[\mathrm{NaHCO_3(s)}] \\ \Delta H^\circ_{\text{recombination}} &= \Delta H_f^\circ[\mathrm{Na_2CO_3(s)}] + \Delta H_f^\circ[\mathrm{H_2O(l)}] + \Delta H_f^\circ[\mathrm{CO_2(g)}] \end{aligned}$$

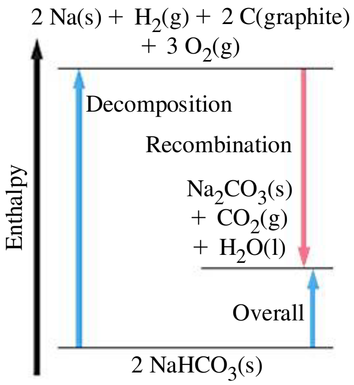
so that

$$\Delta H^\circ = \Delta H_f^\circ[\mathrm{Na_2CO_3(s)}] + \Delta H_f^\circ[\mathrm{H_2O(l)}] + \Delta H_f^\circ[\mathrm{CO_2(g)}] - 2 \times \Delta H_f^\circ[\mathrm{NaHCO_3(s)}]$$

Equation (7.20) is a specific application of the following more general relationship for a standard enthalpy of reaction.

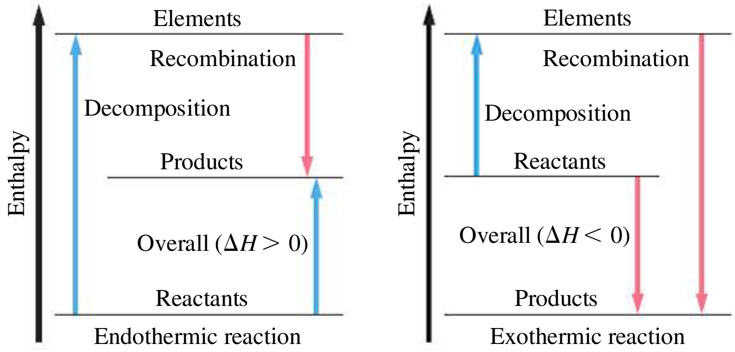
$$\Delta H^\circ = \sum v_{\mathrm{p}} \Delta H_f^\circ(\text{products}) - \sum v_{\mathrm{r}} \Delta H_f^\circ(\text{reactants}) \qquad \textbf{(7.21)}$$

The symbol Σ (Greek, sigma) means "the sum of." The terms that are added together are the products of the standard enthalpies of formation (ΔH_f°) and their stoichiometric coefficients, v. One sum is required for the reaction products (subscript p), and another for the initial reactants (subscript r). The enthalpy change of the reaction is the sum of terms for the products *minus* the sum of terms for the reactants. Equation (7.21) avoids the manipulation of a number of chemical equations. The state function basis for equation (7.21) is shown in Figure 7-21 and is applied in Example 7-11.



$2\,\mathrm{Na(s)} + \mathrm{H_2(g)} + 2\,\mathrm{C(graphite)} + 3\,\mathrm{O_2(g)}$
Decomposition
Recombination
$\mathrm{Na_2CO_3(s)} + \mathrm{CO_2(g)} + \mathrm{H_2O(l)}$
Overall
$2\,\mathrm{NaHCO_3(s)}$
Enthalpy

▲ FIGURE 7-20
Computing heats of reaction from standard enthalpies of formation
Enthalpy is a state function, hence ΔH° for the overall reaction $2\,\mathrm{NaHCO_3(s)} \longrightarrow \mathrm{Na_2CO_3(s)} + \mathrm{CO_2(g)} + \mathrm{H_2O(l)}$ is the sum of the enthalpy changes for the two steps shown.



▶ FIGURE 7-21
Diagrammatic representation of equation (7.21)

EXAMPLE 7-11 Calculating $\Delta H°$ from Tabulated Values of $\Delta H_f°$

Let us apply equation (7.21) to calculate the standard enthalpy of combustion of ethane, $C_2H_6(g)$, a component of natural gas.

Analyze

This type of problem is a straightforward application of equation (7.21). Appendix D has a table of thermodynamic data which includes the standard enthalpy of formation for a number of compounds.

Solve

The reaction is

$$C_2H_6(g) + \frac{7}{2}O_2(g) \longrightarrow 2\,CO_2(g) + 3\,H_2O(l)$$

The relationship we need is equation (7.21). The data we substitute into the relationship are from Table 7.2.

$$\begin{aligned}\Delta H° &= \{2\text{ mol } CO_2 \times \Delta H_f°[CO_2(g)] + 3\text{ mol } H_2O \times \Delta H_f°[H_2O(l)]\}\\ &\qquad - \{1\text{ mol } C_2H_6 \times \Delta H_f°[C_2H_6(g)] + \frac{7}{2}\text{mol } O_2 \times \Delta H_f°[O_2(g)]\}\\ &= 2\text{ mol } CO_2 \times (-393.5\text{ kJ/mol } CO_2) + 3\text{ mol } H_2O \times (-285.8\text{ kJ/mol } H_2O)\\ &\qquad - 1\text{ mol } C_2H_6 \times (-84.7\text{ kJ/mol } C_2H_6) - \frac{7}{2}\text{mol } O_2 \times 0\text{ kJ/mol } O_2\\ &= -787.0\text{ kJ} - 857.4\text{ kJ} + 84.7\text{ kJ} = -1559.7\text{ kJ}\end{aligned}$$

Assess

In these types of problems, we must make sure to subtract the sum of the products' standard enthalpies of formation from the sum of the reactants' standard enthalpies of formation. We must also keep in mind that the standard enthalpy of formation of an element in its reference form is zero. Thus, we can drop the term involving $\Delta H_f°[O_2(g)]$ at any time in the calculation.

PRACTICE EXAMPLE A: Use data from Table 7.2 to calculate the standard enthalpy of combustion of ethanol, $CH_3CH_2OH(l)$, at 298.15 K.

PRACTICE EXAMPLE B: Calculate the standard enthalpy of combustion at 298.15 K *per mole* of a gaseous fuel that contains C_3H_8 and C_4H_{10} in the mole fractions 0.62 and 0.38, respectively.

A type of calculation as important as the one illustrated in Example 7-11 is the determination of an unknown $\Delta H_f°$ value from a set of known $\Delta H_f°$ values and a known standard enthalpy of reaction, $\Delta H°$. As shown in Example 7-12, the essential step is to rearrange expression (7.21) to isolate the unknown $\Delta H_f°$ on one side of the equation. Also shown is a way of organizing the data that you may find helpful.

EXAMPLE 7-12 Calculating an Unknown ΔH_f° Value

Use the data here and in Table 7.2 to calculate ΔH_f° of benzene, $C_6H_6(l)$.

$$2\,C_6H_6(l) + 15\,O_2(g) \longrightarrow 12\,CO_2(g) + 6\,H_2O(l) \qquad \Delta H^\circ = -6535\text{ kJ}$$

Analyze

We have a chemical equation and know the standard enthalpy of reaction. We are asked to determine a standard enthalpy of formation. Equation (7.21) relates a standard enthalpy of reaction to standard enthalpy of formations for reactants and products. To begin, we organize the data needed in the calculation by writing the chemical equation for the reaction with ΔH_f° data listed under the chemical formulas.

Solve

$$\begin{array}{lccccccc} & 2\,C_6H_6(l) & + & 15\,O_2(g) & \longrightarrow & 12\,CO_2(g) & + & 6\,H_2O(l) \qquad \Delta H^\circ = -6535\text{ kJ} \\ \Delta H_f^\circ\text{, kJ/mol} & ? & & 0 & & -393.5 & & -285.8 \end{array}$$

Now, we can substitute known data into expression (7.21) and rearrange the equation to obtain a lone term on the left: $\Delta H_f^\circ[C_6H_6(l)]$. The remainder of the problem simply involves numerical calculations.

$$\Delta H^\circ = \{12\text{ mol }CO_2 \times -(393.5\text{ kJ/mol }CO_2) + 6\text{ mol }H_2O \times (-285.8\text{ kJ/mol }H_2O)\}$$
$$- 2\text{ mol }C_2H_6 \times \Delta H_f^\circ[C_6H_6(l)] = -6535\text{ kJ}$$

$$\Delta H_f^\circ[C_6H_6(l)] = \frac{\{-4722\text{ kJ} - 1715\text{ kJ}\} + 6535\text{ kJ}}{2\text{ mol }C_6H_6} = 49\text{ kJ/mol }C_6H_6(l)$$

Assess

By organizing the data as shown, we were able to identify what is unknown and see how to use equation (7.21). To obtain the correct answer, we also needed to use the correct states for the compounds. In combustion reactions, the water in the product is always liquid. If we had used the standard enthalpy of formation for gaseous water, we would have obtained the wrong answer.

PRACTICE EXAMPLE A: The overall reaction that occurs in photosynthesis in plants is

$$6\,CO_2(g) + 6\,H_2O(l) \longrightarrow C_6H_{12}O_6(s) + 6\,O_2(g) \qquad \Delta H^\circ = 2803\text{ kJ}$$

Determine the standard enthalpy of formation of glucose, $C_6H_{12}O_6(s)$, at 298 K.

PRACTICE EXAMPLE B: A handbook lists the standard enthalpy of combustion of gaseous dimethyl ether at 298 K as $-31.70\text{ kJ/g}(CH_3)_2O(g)$. What is the standard molar enthalpy of formation of dimethyl ether at 298 K?

Ionic Reactions in Solutions

Many chemical reactions in aqueous solution are best thought of as reactions between ions and best represented by net ionic equations. Consider the neutralization of a strong acid by a strong base. Using a somewhat more accurate enthalpy of neutralization than we obtained in Example 7-4, we can write

$$H^+(aq) + OH^-(aq) \longrightarrow H_2O(l) \qquad \Delta H^\circ = -55.8\text{ kJ} \qquad \textbf{(7.22)}$$

We should also be able to calculate this enthalpy of neutralization by using enthalpy of formation data in expression (7.21), but this requires us to have enthalpy of formation data for individual ions. And there is a slight problem in getting these. We cannot create ions of a single type in a chemical reaction. We always produce cations and anions simultaneously, as in the reaction of sodium and chlorine to produce Na^+ and Cl^- in NaCl. We must choose a particular ion to which we assign an enthalpy of formation of *zero* in its aqueous solutions. We then compare the enthalpies of formation of other ions to this reference ion. The ion we arbitrarily choose for our zero is $H^+(aq)$. Now let us see how we can use expression (7.21) and data from equation (7.22) to determine the enthalpy of formation of $OH^-(aq)$.

$$\Delta H^\circ = 1\text{ mol H}_2\text{O} \times \Delta H_f^\circ[\text{H}_2\text{O(l)}] - \{1\text{ mol H}^+ \times \Delta H_f^\circ[\text{H}^+\text{(aq)}] + 1\text{ mol OH}^- \times \Delta H_f^\circ[\text{OH}^-\text{(aq)}]\} = -55.8\text{ kJ}$$

$$\Delta H_f^\circ[\text{OH}^-\text{(aq)}] = \frac{55.8\text{ kJ} + (1\text{ mol H}_2\text{O} \times \Delta H_f^\circ[\text{H}_2\text{O(l)}]) - (1\text{ mol H}^+ \times \Delta H_f^\circ[\text{H}^+\text{(aq)}])}{1\text{ mol OH}^-}$$

$$\Delta H_f^\circ[\text{OH}^-\text{(aq)}] = \frac{55.8\text{ kJ} - 285.8\text{ kJ} - 0\text{ kJ}}{1\text{ mol OH}^-} = -230.0\text{ kJ/mol OH}^-$$

Table 7.3 lists data for several common ions in aqueous solution. Enthalpies of formation in solution depend on the solute concentration. These data are representative for *dilute* aqueous solutions (about 1 M), the type of solution that we normally deal with. Some of these data are used in Example 7-13.

TABLE 7.3 Some Standard Molar Enthalpies of Formation, ΔH_f° of Ions in Aqueous Solution at 298.15 K

Ion	kJ/mol	Ion	kJ/mol
H^+	0	OH^-	−230.0
Li^+	−278.5	Cl^-	−167.2
Na^+	−240.1	Br^-	−121.6
K^+	−252.4	I^-	−55.19
NH_4^+	−132.5	NO_3^-	−205.0
Ag^+	105.6	CO_3^{2-}	−677.1
Mg^{2+}	−466.9	S^{2-}	33.05
Ca^{2+}	−542.8	SO_4^{2-}	−909.3
Ba^{2+}	−537.6	$S_2O_3^{2-}$	−648.5
Cu^{2+}	64.77	PO_4^{3-}	−1277
Al^{3+}	−531		

EXAMPLE 7-13 Calculating the Enthalpy Change in an Ionic Reaction

Given that $\Delta H_f^\circ[\text{BaSO}_4\text{(s)}] = -1473$ kJ/mol, what is the standard enthalpy change for the precipitation of barium sulfate?

Analyze

First, write the net ionic equation for the reaction and introduce the relevant data. Then make use of equation (7.21).

Solve

Start by organizing the data in a table.

	$Ba^{2+}(aq)$	$+\ SO_4^{2-}(aq)$	$\longrightarrow BaSO_4(s)$	$\Delta H^\circ = ?$
ΔH_f°, kJ/mol	−537.6	−909.3	−1473	

Then substitute data into equation (7.21).

$$\begin{aligned}\Delta H^\circ &= 1\text{ mol BaSO}_4 \times \Delta H_f^\circ[\text{BaSO}_4\text{(s)}] - 1\text{ mol Ba}^{2+} \times \Delta H_f^\circ[\text{Ba}^{2+}\text{(aq)}] - 1\text{ mol SO}_4^{2-} \times \Delta H_f^\circ[\text{SO}_4^{2-}\text{(aq)}]\\ &= 1\text{ mol BaSO}_4 \times (-1473\text{ kJ/mol BaSO}_4) - 1\text{ mol Ba}^{2+} \times (-537.6\text{ kJ/mol Ba}^{2+})\\ &\quad - 1\text{ mol SO}_4^{2-} \times (-909.3\text{ kJ/mol SO}_4^{2-})\\ &= -1473\text{ kJ} + 537.6\text{ kJ} + 909.3\text{ kJ} = -26\text{ kJ}\end{aligned}$$

Assess

The standard enthalpy of reaction determined here is the heat given off by the system (i.e., the ionic reaction).

PRACTICE EXAMPLE A: Given that $\Delta H_f^\circ[\text{AgI(s)}] = -61.84$ kJ/mol, what is the standard enthalpy change for the precipitation of silver iodide?

PRACTICE EXAMPLE B: The standard enthalpy change for the precipitation of $Ag_2CO_3(s)$ is −39.9 kJ per mole of $Ag_2CO_3(s)$ formed. What is $\Delta H_f^\circ[\text{Ag}_2\text{CO}_3\text{(s)}]$?

7-10 CONCEPT ASSESSMENT

Is it possible to calculate a heat of reaction at 373.15 K by using standard enthalpies of formation at 298.15 K? If so, explain how you would do this, and indicate any additional data you might need.

7-9 Fuels as Sources of Energy

One of the most important uses of thermochemical measurements and calculations is in assessing materials as energy sources. For the most part, these materials, called fuels, liberate heat through the process of combustion. We will briefly survey some common fuels, emphasizing matters that a thermochemical background helps us to understand.

Fossil Fuels

The bulk of current energy needs are met by petroleum, natural gas, and coal—so-called fossil fuels. These fuels are derived from plant and animal life of millions of years ago. The original source of the energy locked into these fuels is solar energy. In the process of *photosynthesis*, CO_2 and H_2O, in the presence of enzymes, the pigment chlorophyll, and sunlight, are converted to *carbohydrates*. These are compounds with formulas $C_m(H_2O)_n$, where m and n are integers. For example, in the sugar glucose $m = n = 6$, that is, $C_6(H_2O)_6 = C_6H_{12}O_6$. Its formation through photosynthesis is an *endothermic* process, represented as

◀ Although the formula $C_m(H_2O)_n$ suggests a "hydrate" of carbon, in carbohydrates, there are no H_2O units, as there are in hydrates, such as $CuSO_4 \cdot 5\,H_2O$. H and O atoms are simply found in the same numerical ratio as in H_2O.

$$6\,CO_2(g) + 6\,H_2O(l) \xrightarrow[\text{sunlight}]{\text{chlorophyll}} C_6H_{12}O_6(s) + 6\,O_2(g) \qquad \Delta H^\circ = +2.8 \times 10^3\ \text{kJ} \tag{7.23}$$

When reaction (7.23) is reversed, as in the combustion of glucose, heat is evolved. The combustion reaction is *exothermic*.

The complex carbohydrate cellulose, with molecular masses ranging up to 500,000 u, is the principal structural material of plants. When plant life decomposes in the presence of bacteria and out of contact with air, O and H atoms are removed and the approximate carbon content of the residue increases in the progression

$$\text{Peat} \longrightarrow \text{lignite (32\% C)} \longrightarrow \text{sub-bituminous coal (40\% C)} \longrightarrow$$
$$\text{bituminous coal (60\% C)} \longrightarrow \text{anthracite coal (80\% C)}$$

For this process to progress all the way to anthracite coal may take about 300 million years. Coal, then, is a combustible organic rock consisting of carbon, hydrogen, and oxygen, together with small quantities of nitrogen, sulfur, and mineral matter (ash). (One proposed formula for a "molecule" of bituminous coal is $C_{153}H_{115}N_3O_{13}S_2$.)

Petroleum and natural gas formed in a different way. The remains of plants and animals living in ancient seas fell to the ocean floor, where they were decomposed by bacteria and covered with sand and mud. Over time, the sand and mud were converted to sandstone by the weight of overlying layers of sand and mud. The high pressures and temperatures resulting from this overlying sandstone rock formation transformed the original organic matter into petroleum and natural gas. The ages of these deposits range from about 250 million to 500 million years.

A typical natural gas consists of about 85% methane (CH_4), 10% ethane (C_2H_6), 3% propane (C_3H_8), and small quantities of other combustible and noncombustible gases. A typical petroleum consists of several hundred different hydrocarbons that range in complexity from C_1 molecules (CH_4) to C_{40} or higher (such as $C_{40}H_{82}$).

TABLE 7.4 Approximate Heats of Combustion of Some Fuels

	Heat of Combustion
Fuel	kJ/g
Municipal waste	−12.7
Cellulose	−17.5
Pinewood	−21.2
Methanol	−22.7
Peat	−20.8
Bituminous coal	−28.3
Isooctane (a component of gasoline)	−47.8
Natural gas	−49.5

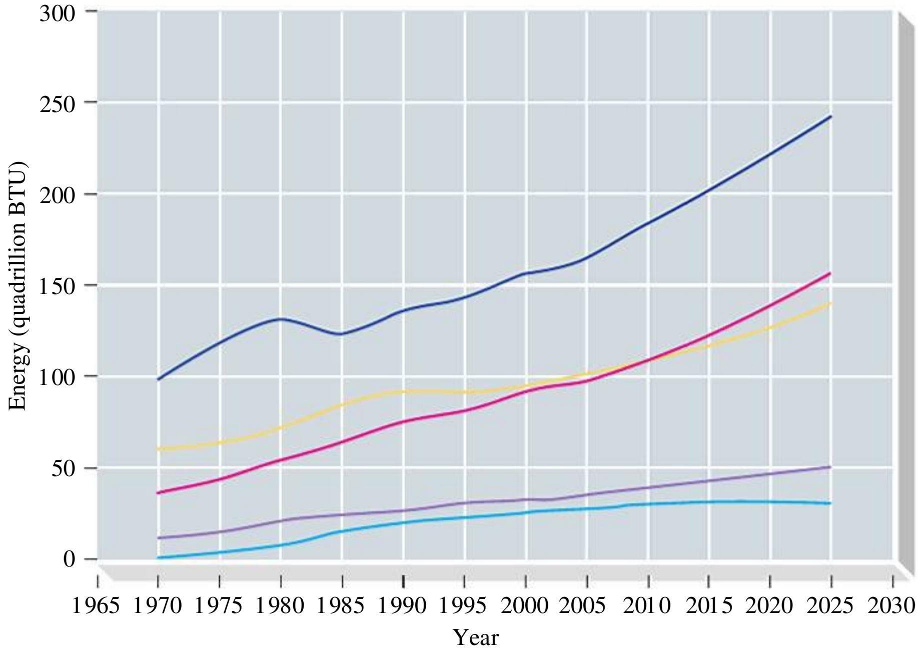
One way to compare different fuels is through their heats of combustion: In general, *the higher the heat of combustion, the better the fuel*. Table 7.4 lists approximate heats of combustion for the fossil fuels. These data show that *biomass* (living matter or materials derived from it—wood, alcohols, municipal waste) is a viable fuel, but that fossil fuels yield more energy per unit mass.

Problems Posed by Fossil Fuel Use There are two fundamental problems with the use of fossil fuels. First, fossil fuels are essentially *nonrenewable* energy sources. The world consumption of fossil fuels is expected to increase for the foreseeable future (Fig. 7-22), but when will Earth's supply of these fuels run out? There is currently a debate about whether oil production has peaked now and is about to decline, or whether it will peak more toward the middle of the this century. The second problem with fossil fuels is their environmental effect. Sulfur impurities in fuels produce oxides of sulfur. The high temperatures associated with combustion cause the reaction of N_2 and O_2 in air to form oxides of nitrogen. Oxides of sulfur and nitrogen are implicated in air pollution and are important contributors to the environmental problem known as acid rain. Another inevitable product of the combustion of fossil fuels is carbon dioxide, one of the "greenhouse" gases leading to *global warming* and potential changes in Earth's climate.

▶ Environmental issues associated with oxides of sulfur and nitrogen are discussed more fully in later chapters.

Global Warming—An Environmental Issue Involving Carbon Dioxide We do not normally think of CO_2 as an air pollutant because it is essentially nontoxic and is a natural and necessary component of air. Its ultimate effect on the environment, however, could be very significant. A buildup of $CO_2(g)$ in the atmosphere may disturb the energy balance on Earth.

Earth's atmosphere, discussed in Focus On 6 on the Mastering Chemistry website, is largely transparent to visible and UV radiation from the sun.



▲ FIGURE 7-22

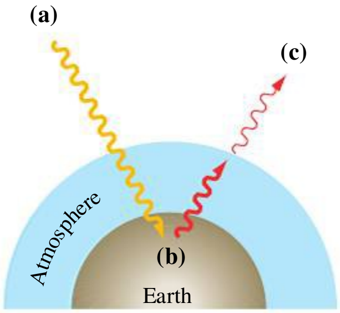
World primary energy consumption by energy source

These graphs show the history of energy consumption since 1970, with predictions to 2025. Petroleum (dark blue line) is seen to be the major source of energy for the foreseeable future, followed by coal (yellow) and natural gas (pink), which are about the same. Other sources of energy included are wind power (purple) and nuclear power (light blue). The unit BTU is a measure of energy and stands for British thermal unit (see Exercise 95). [*Source: www.eia.doe.gov/oiaf/ieo/pdf/ieoreftab_2.pdf*]

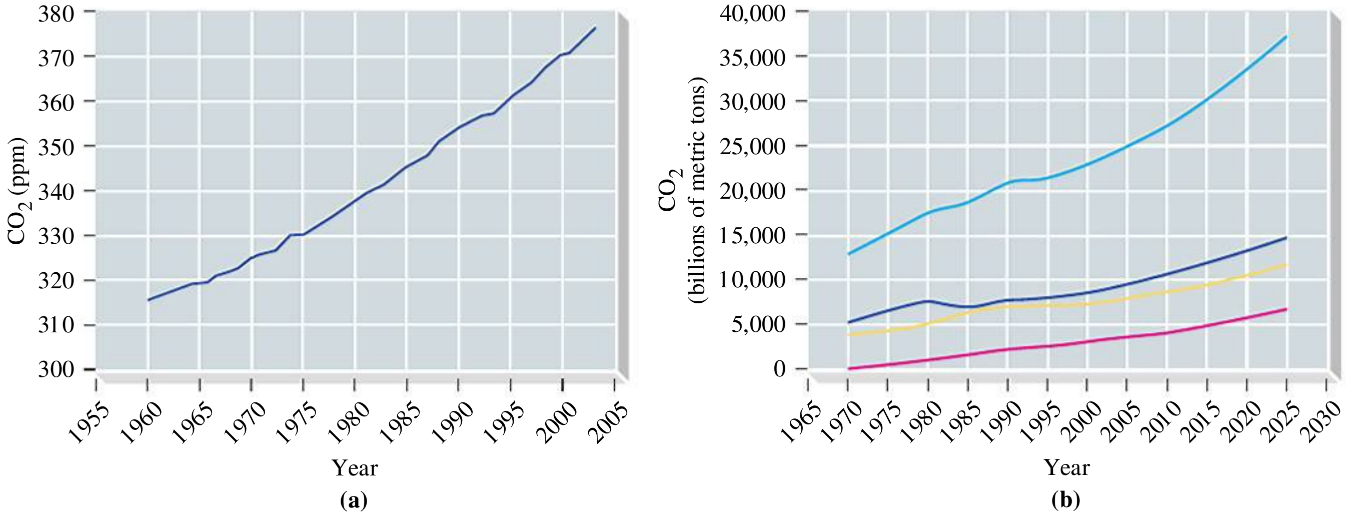
This radiation is absorbed at Earth's surface, which is warmed by it. Some of this absorbed energy is reradiated as infrared radiation. Certain atmospheric gases, primarily CO_2, methane, and water vapor, absorb some of this infrared radiation, and the energy thus retained in the atmosphere produces a warming effect. This process, outlined in Figure 7-23, is often compared to the retention of thermal energy in a greenhouse and is called the "greenhouse effect."* The natural greenhouse effect is essential in maintaining the proper temperature for life on Earth. Without it, Earth would be permanently covered with ice.

Over the past 400,000 years, the atmospheric carbon dioxide concentration has varied from 180 to 300 parts per million with the preindustrial-age concentration at about 285 ppm. By 2005, the level had increased to about 376 ppm and is still rising (Fig. 7-24). Increasing atmospheric carbon dioxide concentrations result from the burning of carbon-containing fuels such as wood, coal, natural gas, and gasoline (Fig. 7-24) and from the deforestation of tropical regions (plants, through photosynthesis, consume CO_2 from the atmosphere). The expected effect of a CO_2 buildup is an increase in Earth's average temperature, a **global warming**. Some estimates are that a doubling of the CO_2 content over that of preindustrial times could occur before the end of the present century and that this doubling could produce an average global temperature increase of 1.5 to 4.5 °C.

Predicting the probable effects of a CO_2 buildup in the atmosphere is done largely through computer models, and it is very difficult to know all the factors that should be included in these models and the relative importance of these factors. For example, global warming could lead to the increased evaporation of water and increased cloud formation. In turn, an increased cloud cover could reduce the amount of solar radiation reaching Earth's surface and, to some extent, offset global warming.



▲ FIGURE 7-23
The "greenhouse" effect
(a) Some incoming radiation from sunlight is reflected back into space by the atmosphere, and some, such as certain UV light, is absorbed by stratospheric ozone. Much of the radiation from sunlight, however, reaches Earth's surface. **(b)** Earth's surface re-emits some of this energy as infrared radiation. **(c)** Infrared radiation leaving Earth's atmosphere is less intense than that emitted by Earth's surface because some of this radiation is absorbed by CO_2 and other greenhouse gases and warms the atmosphere.



▲ FIGURE 7-24
Increasing carbon dioxide content of the atmosphere
(a) The global average atmospheric carbon dioxide level over a 50-year span, expressed in parts per million by volume, as measured by a worldwide cooperative sampling network. **(b)** The actual and predicted CO_2 emissions for a 55-year span due to the combustion of natural gas (pink line), coal (yellow), and petroleum (dark blue), together with the total of all CO_2 emissions (light blue). The CO_2 content of the atmosphere continues to increase, from approximately 375 ppm in 2003 to 385 ppm in 2008.

---

*Glass, like CO_2, is transparent to visible and some UV light but absorbs infrared radiation. The glass in a greenhouse, though, acts primarily to prevent the bulk flow of warm air out of the greenhouse.

Some of the significant possible effects of global warming are

- local temperature changes. The average annual temperature for Alaska and Northern Canada has increased by 1.9 °C over the past 50 years. Alaskan winter temperatures have increased by an average of 3.5 °C over this same time period.
- a rise in sea level caused by the thermal expansion of seawater and increased melting of continental ice caps. A potential increase in sea level of up to 1 m by 2100 would displace tens of millions of inhabitants in Bangladesh alone.
- the migration of plant and animal species. Vegetation now characteristic of certain areas of the globe could migrate into regions several hundred kilometers closer to the poles. The areas in which diseases, such as malaria, are endemic could also expand.

▲ An ice core from the ice sheet in Antarctica is cut into sections in a refrigerated clean room. The ice core is then analyzed to determine the amount and type of trapped gases and trace elements it contains. These data provide information regarding past changes in climate and current trends in the pollution of the atmosphere.

Although some of the current thinking involves speculation, a growing body of evidence supports the likelihood of global warming, also called climate change. For example, analyses of tiny air bubbles trapped in the Antarctic ice cap show a strong correlation between the atmospheric CO_2 content and temperature for the past 160,000 years—low temperatures during periods of low CO_2 levels and higher temperatures with higher levels of CO_2.

CO_2 is not the only greenhouse gas. Several gases are even stronger infrared absorbers—specifically, methane (CH_4), ozone (O_3), nitrous oxide (N_2O), and chlorofluorocarbons (CFCs). Furthermore, atmospheric concentrations of some of these gases have been growing at a faster rate than that of CO_2. No strategies beyond curtailing the use of chlorofluorocarbons and fossil fuels have emerged for countering a possible global warming. Like several other major environmental issues, some aspects of climate change are not well understood, and research, debate, and action are all likely to occur simultaneously for a long time to come.

Coal and Other Energy Sources

In the United States, reserves of coal far exceed those of petroleum and natural gas. Despite this relative abundance, however, the use of coal has not increased significantly in recent years. In addition to the environmental effects cited above, the expense and hazards involved in the deep mining of coal are considerable. Surface mining, which is less hazardous and expensive than deep mining, is also more damaging to the environment. One promising possibility for using coal reserves is to convert coal to gaseous or liquid fuels, either in surface installations or while the coal is still underground.

Gasification of Coal Before cheap natural gas became available in the 1940s, gas produced from coal (variously called producer gas, town gas, or city gas) was widely used in the United States. This gas was manufactured by passing steam and air through heated coal and involved such reactions as

$$\text{C(graphite)} + H_2O(g) \longrightarrow CO(g) + H_2(g) \qquad \Delta H^\circ = +131.3\ \text{kJ} \qquad \textbf{(7.24)}$$

$$CO(g) + H_2O(g) \longrightarrow CO_2(g) + H_2(g) \qquad \Delta H^\circ = -41.2\ \text{kJ} \qquad \textbf{(7.25)}$$

$$2\text{C(graphite)} + O_2(g) \longrightarrow 2\,CO(g) \qquad \Delta H^\circ = -221.0\ \text{kJ} \qquad \textbf{(7.26)}$$

$$\text{C(graphite)} + 2\,H_2(g) \longrightarrow CH_4(g) \qquad \Delta H^\circ = -74.8\ \text{kJ} \qquad \textbf{(7.27)}$$

The principal gasification reaction (7.24) is highly endothermic. The heat requirements for this reaction are met by the carefully controlled partial burning of coal (reaction 7.26).

A typical producer gas consists of about 23% CO, 18% H_2, 8% CO_2, and 1% CH_4 by volume. It also contains about 50% N_2 because air is used in its production. Because the N_2 and CO_2 are noncombustible, producer gas has only about 10% to 15% of the heat value of natural gas. Modern gasification processes include several features:

1. They use $O_2(g)$ instead of air, thereby eliminating $N_2(g)$ in the product.
2. They provide for the removal of noncombustible $CO_2(g)$ and sulfur impurities. For example,

$$\begin{aligned} CaO(s) + CO_2(g) &\longrightarrow CaCO_3(s) \\ 2\,H_2S(g) + SO_2(g) &\longrightarrow 3\,S(s) + 2\,H_2O(g) \end{aligned}$$

3. They include a step (called *methanation*) to convert CO and H_2, in the presence of a catalyst, to CH_4.

$$CO(g) + 3\,H_2(g) \xrightarrow{\text{catalyst}} CH_4(g) + H_2O(1)$$

The product is called *substitute natural gas* (SNG), a gaseous mixture with composition and heat value similar to that of natural gas.

Liquefaction of Coal The first step in obtaining liquid fuels from coal generally involves gasification of coal, as in reaction (7.24). This step is followed by catalytic reactions in which liquid hydrocarbons are formed.

$$n\,CO + (2n + 1)\,H_2 \longrightarrow C_nH_{2n+2} + n\,H_2O$$

In still another process, liquid methanol is formed.

$$CO(g) + 2\,H_2(g) \longrightarrow CH_3OH(l) \qquad \textbf{(7.28)}$$

In 1942, some 32 million gallons of aviation fuel were made from coal in Germany. In South Africa, the Sasol process for coal liquefaction has been a major source of gasoline and a variety of other petroleum products and chemicals for more than 50 years.

Methanol

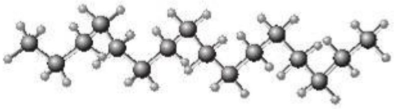
Methanol, CH_3OH, can be obtained from coal by reaction (7.28). It can also be produced by thermal decomposition (pyrolysis) of wood, manure, sewage, or municipal waste. The heat of combustion of methanol is only about one-half that of a typical gasoline on a mass basis, but methanol has a high octane number—106—compared with 100 for the gasoline hydrocarbon isooctane and about 92 for premium gasoline. Methanol has been tested and used as a fuel in internal combustion engines and is cleaner burning than gasoline. Methanol can also be used for space heating, electric power generation, fuel cells, and as a reactant to make a variety of other organic compounds.

Ethanol

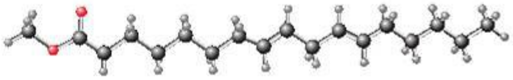
Ethanol, C_2H_5OH, is produced mostly from ethylene, C_2H_4, which in turn is derived from petroleum. Current interest centers on the production of ethanol by the fermentation of organic matter, a process known throughout recorded history. Ethanol production by fermentation is probably most advanced in Brazil, where sugarcane and cassava (manioc) are the plant matter (biomass) used. In the United States, corn-based ethanol is used chiefly as an additive to gasoline to improve its octane rating and reduce air pollution. Also, a 90% gasoline–10% ethanol mixture is used as an automotive fuel under the name *gasohol*.

Biofuels

Biofuels are renewable energy sources that are similar to fossil fuels. Biofuels are fuels derived from dead biological material, most commonly plants. Fossil fuels are derived from biological material that has been dead for a very long time. The use of biofuels is not new; several car inventors had envisioned their vehicles running on such fuels as peanut oil, hemp-derived fuel, and ethanol. Reacting vegetable oil with a base–alcohol mixture produces a compound commonly called a biodiesel. A typical petro–diesel compound is the hydrocarbon cetane $(C_{16}H_{34})$, and the typical biodiesel compound contains oxygen atoms, as illustrated in the figure below. The standard enthalpies of combustion of the petro–diesel and the biodiesel are very similar.



Cetane (liquid)
$\Delta H_f^\circ = -456.3\ \text{kJ mol}^{-1}$
$\Delta H_{\text{comb}}^\circ = -10699.1\ \text{kJ mol}^{-1}$



Linoleic acid methyl ester (liquid)
$\Delta H_f^\circ = -604.88\ \text{kJ mol}^{-1}$
$\Delta H_{\text{comb}}^\circ = -11690.1\ \text{kJ mol}^{-1}$

Although biofuels are appealing replacements for fossil fuels, their widespread adoption has several potential drawbacks. One major concern is the food-versus-fuel issue. Typical plants used for food (e.g., sugar cane) are sources of biofuels, which drives up the cost of food. A positive aspect of biofuels is that they are carbon neutral; that is, the $CO_2(g)$ produced by the burning of a biofuel is then used by plants for new growth, resulting in no net gain of carbon in the atmosphere. Biofuels and their use have many other advantages and disadvantages. Importantly, chemical knowledge of these compounds is needed to address these issues.

Hydrogen

Another fuel with great potential is hydrogen. Its most attractive features are that

- on a per gram basis, its heat of combustion is more than twice that of methane and about three times that of gasoline;
- the product of its combustion is H_2O, not CO and CO_2 as with gasoline.

Currently, the bulk of hydrogen used commercially is made from petroleum and natural gas, but for hydrogen to be a significant fuel of the future, efficient methods must be perfected for obtaining hydrogen from other sources, especially water. Alternative methods of producing hydrogen and the prospects of developing an economy based on hydrogen are discussed later in the text.

Alternative Energy Sources

Combustion reactions are only one means of extracting useful energy from materials. An alternative, for example, is to carry out reactions that yield the same products as combustion reactions in electrochemical cells called *fuel cells*. The energy is released as electricity rather than as heat (see Section 20-5). Solar energy can be used directly, without recourse to photosynthesis. Nuclear processes can be used in place of chemical reactions (Chapter 25). Other alternative sources in various stages of development and use include hydroelectric energy, geothermal energy, and tidal and wind power.

MasteringCHEMISTRY **www.masteringchemistry.com**

Have you ever considered where you get the energy to carry out your daily activities? The Focus On feature for Chapter 7 on the MasteringChemistry site, entitled Fats, Carbohydrates, and Energy Storage, provides some insight into the body's energy storage system.

Summary

7-1 Getting Started: Some Terminology—The subject of a thermochemical study is broken down into the **system** of interest and the portions of the universe with which the system may interact, the **surroundings**. An **open system** can exchange both energy and matter with its surroundings. A **closed system** can exchange only energy and not matter. An **isolated system** can exchange neither energy nor matter with its surroundings (Fig. 7-1). **Energy** is the capacity to do work, and **work** is performed when a force acts through a distance. Energy can be further characterized (Fig. 7-2) as **kinetic energy** (energy associated with matter in motion) or **potential energy** (energy resulting from the position or composition of matter). Kinetic energy associated with random molecular motion is sometimes called **thermal energy**.

7-2 Heat—**Heat** is energy transferred between a system and its surroundings as a result of a temperature difference between the two. In some cases, heat can be transferred at constant temperature, as in a change in state of matter in the system. A quantity of heat is the product of the heat capacity of the system and the temperature change (equation 7.5). In turn, **heat capacity** is the product of mass and **specific heat**, the amount of heat required to change the temperature of one gram of substance by one degree Celsius. Historically, the unit for measuring heat has been the **calorie** (**cal**), but the SI unit of heat is the joule, the same as for other forms of energy (equation 7.2). Energy transfers between a system and its surroundings must conform to the **law of conservation of energy**, meaning that all heat lost by a system is gained by its surroundings (equation 7.6).

7-3 Heats of Reaction and Calorimetry—In a chemical reaction, a change in the **chemical energy** associated with the reactants and products may appear as heat. The **heat of reaction** is the quantity of heat exchanged between a system and its surroundings when the reaction occurs at a constant temperature. In an **exothermic reaction**, heat is given off by the system; in an **endothermic reaction** the system absorbs heat. Heats of reaction are determined in a **calorimeter**, a device for measuring quantities of heat (equation 7.10). Exothermic combustion reactions are usually studied in a **bomb calorimeter** (Fig. 7-5). A common type of calorimeter used in the general chemistry laboratory is constructed from ordinary Styrofoam cups (Fig. 7-6).

7-4 Work—In some reactions an energy transfer between a system and its surroundings occurs as work. This is commonly the work involved in the expansion or compression of gases (Fig. 7-8) and is called **pressure–volume work** (equation 7.11).

7-5 The First Law of Thermodynamics—**Internal energy** (U) is the total energy (both kinetic and potential) in a system. The **first law of thermodynamics** relates changes in the internal energy of a system (ΔU) to the quantities of heat (q) and work (w) exchanged between the system and its surroundings. The relationship is $\Delta U = q + w$ (equation 7.12) and requires that a set of sign conventions be consistently followed. A **function of state** (**state function**) has a value that depends only on the exact condition or state in which a system is found and not on how that state was reached. Internal energy is a state function. A path-dependent function, such as heat or work, depends on how a change in a system is achieved. A change that is accomplished through an infinite number of infinitesimal steps is a **reversible process** (Fig. 7-12), whereas a change accomplished in one step or a series of finite steps is **irreversible**.

7-6 Heats of Reaction: ΔU and ΔH—In a chemical reaction with work limited to pressure–volume work and conducted at constant volume, the heat of reaction is equal to the change in internal energy (equation 7.13). For reactions at constant pressure a more useful function is **enthalpy** (H), defined as the internal energy (U) of a system plus the pressure–volume product (PV). The **enthalpy change** (ΔH) in a reaction proves to be the heat of reaction at constant pressure (equation 7.14). Most heats of reaction are reported as ΔH values. A substance under a pressure of 1 bar (10^5 Pa) and at the temperature of interest is said to be in its **standard state**. If the reactants and products of a reaction are in their standard states, the enthalpy change in a reaction is called the **standard enthalpy of reaction** and designated as $\Delta H°$. Enthalpy changes can be represented schematically through **enthalpy diagrams** (Fig. 7-15).

7-7 Indirect Determination of ΔH: Hess's Law—Often an unknown ΔH value can be established indirectly through **Hess's law**, which states that an overall enthalpy change is the sum of the enthalpy changes of the individual steps leading to the overall process (Fig. 7-17).

7-8 Standard Enthalpies of Formation—By arbitrarily assigning an enthalpy of zero to the reference forms of the elements in their standard states, the enthalpy change in the formation of a compound from its elements becomes a **standard enthalpy of formation** (ΔH_f°). Using tabulated standard enthalpies of formation (Table 7.2), it is possible to calculate standard enthalpies of reactions without having to perform additional experiments (equation 7.21).

7-9 Fuels as Sources of Energy—One of the chief applications of thermochemistry is in the study of the combustion of fuels as energy sources. Currently, the principal fuels are the fossil fuels, but potential alternative fuels are also mentioned in this chapter and discussed in more depth later in the text. One of the problems with the use of fossil fuels is the potential for **global warming**.

Integrative Example

When charcoal is burned in a limited supply of oxygen in the presence of H_2O, a mixture of CO, H_2, and other noncombustible gases (mostly CO_2) is obtained. Such a mixture is called *synthesis gas*. This gas can be used to synthesize organic compounds, or it can be burned as a fuel. A typical synthesis gas consists of 55.0% CO(g), 33.0% $H_2(g)$, and 12.0% noncombustible gases (mostly CO_2), *by volume*. To what temperature can 25.0 kg water at 25.0 °C be heated with the heat liberated by the combustion of 0.205 m^3 of this typical synthesis gas, measured at 25.0 °C and 102.6 kPa pressure?

Analyze

First, use the ideal gas equation to calculate the total number of moles of gas, and then use equation (6.17) to establish the number of moles of each combustible gas. Next, write an equation for the combustion of each gas. Use these equations and enthalpy of formation data to calculate the total amount of heat released by the combustion. Finally, use equation (7.5) to calculate the temperature increase when this quantity of heat is absorbed by the 25.0 kg of water. The final water temperature is then easily established.

Solve

Substitute the applicable data into the ideal gas equation using SI units, with $R = 8.3145\ \mathrm{m^3\ Pa\ mol^{-1}\ K^{-1}}$. Solve for n.

$$n = \frac{PV}{RT} = \frac{102.6\ \mathrm{kPa} \times 1000\ \mathrm{Pa/1\ kPa} \times 0.205\ \mathrm{m^3}}{8.3145\ \mathrm{m^3\ Pa\ mol^{-1}\ K^{-1}} \times 298.2\ \mathrm{K}}$$
$$= 8.48\ \text{mol gas}$$

Now, apportion the 8.48 moles among the three gases present, converting the volume percents to mole fractions and using equation (6.17).

$$n_{CO} = n_{tot} \times x_{CO} = 8.48\ \text{mol} \times 0.550 = 4.66\ \text{mol CO}$$
$$n_{H_2} = n_{tot} \times x_{H_2} = 8.48\ \text{mol} \times 0.330 = 2.80\ \text{mol}\ H_2$$

(remaining gas noncombustible)

Write an equation for the combustion of CO(g), list ΔH_f° data beneath the equation, and determine ΔH_{comb}° per mole of CO(g).

$$CO(g) + \frac{1}{2}O_2(g) \longrightarrow CO_2(g)$$

ΔH_f°: −110.5 kJ/mol −393.5 kJ/mol

$$\Delta H_{comb}^\circ = 1\ \text{mol}\ CO_2 \times (-393.5\ \text{kJ/mol}\ CO_2) - 1\ \text{mol CO} \times (-110.5\ \text{kJ/mol CO})$$
$$= -283.0\ \text{kJ}$$

Write another equation for the combustion of $H_2(g)$, again listing ΔH_f° data beneath the equation, and determining ΔH_{comb}° per mole of $H_2(g)$.

$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l)$$

ΔH_f°: 0 kJ/mol −285.8 kJ/mol

$$\Delta H_{comb}^\circ = 1\ \text{mol}\ H_2O \times (-285.8\ \text{kJ/mol}\ H_2O) = -285.8\ \text{kJ}$$

Determine the total heat released in the combustion of the amounts of CO and H_2 in the 0.205 m^3 of gas.

$$4.66\ \text{mol CO} \times (-283.0\ \text{kJ/mol CO}) + 2.80\ \text{mol}\ H_2 \times (-285.8\ \text{kJ/mol}\ H_2)$$
$$= -2.12 \times 10^3\ \text{kJ}$$

The quantity of heat absorbed by the 25.0 kg of water is

$$q_{water} = -q_{comb}$$
$$= -\left(-2.12 \times 10^3\ \text{kJ} \times \frac{1000\ \text{J}}{1\ \text{kJ}}\right) = 2.12 \times 10^6\ \text{J}$$

Rearrange equation (7.5) to solve for the temperature change in the 2.50×10^4 g (25.0 kg) of water.

$$\Delta T = \frac{q_{water}}{\text{mass water} \times \text{sp ht water}}$$

$$\Delta T = \frac{2.12 \times 10^6\ \text{J}}{\left(2.50 \times 10^4\ \text{g}\ H_2O \times \dfrac{4.18\ \text{J}}{\text{g}\ H_2O\,°C}\right)} = 20.3\ °C$$

From the initial temperature and the temperature change, determine the final temperature.

$$T_f = T_i + \Delta T = 25.0\ °C + 20.3\ °C = 45.3\ °C$$

Assess

The assumption that the gas sample obeys the ideal gas law is probably valid since the temperature of the gas (25.0 °C) is not particularly low and the gas pressure, about 1 atm, is not particularly high. However, the implicit assumption that all the heat of combustion could be transferred to the water was probably not valid. If the transfer were to occur in an ordinary gas-fired water heater, some of the heat would undoubtedly be lost through the exhaust vent. Thus, our calculation was of the highest temperature that could possibly be attained. Note that in using the ideal gas equation the simplest approach was to work with SI units because those were the units of the data that were given.

PRACTICE EXAMPLE A: The enthalpy of combustion for 1-hexadecene, $C_{16}H_{32}$, is $-10539.0\ \mathrm{kJ\,mol^{-1}}$, and that of hexadecane, $C_{16}H_{34}$, is $-10699.1\ \mathrm{kJ\,mol^{-1}}$. What is the enthalpy of hydrogenation of 1-hexadecene to hexadecane?

PRACTICE EXAMPLE B: A chemist mixes 56 grams of CaO, powdered lime, with 100 mL of water at 20 °C. After the completion of the reaction, $CaO(s) + H_2O(l) \rightarrow Ca(OH)_2(s)$, what are the contents of the reaction vessel? [*Hint:* Assume that the heat released by the reaction is absorbed by the water.]

MasteringCHEMISTRY

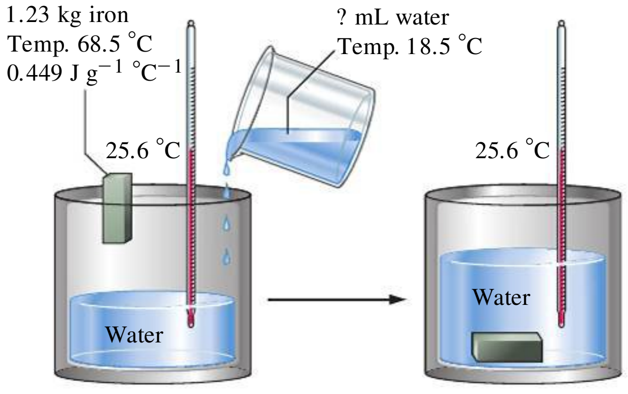
Exercises

Heat Capacity (Specific Heat)

1. Calculate the quantity of heat, in kilojoules, **(a)** required to raise the temperature of 9.25 L of water from 22.0 to 29.4 °C; **(b)** associated with a 33.5 °C decrease in temperature in a 5.85 kg aluminum bar (specific heat of aluminum $= 0.903\ \mathrm{J\,g^{-1}\,°C^{-1}}$).
2. Calculate the final temperature that results when **(a)** a 12.6 g sample of water at 22.9 °C absorbs 875 J of heat; **(b)** a 1.59 kg sample of platinum at 78.2 °C gives off 1.05 kcal of heat (sp ht of Pt $= 0.032\ \mathrm{cal\,g^{-1}\,°C^{-1}}$).
3. Refer to Example 7-2. The experiment is repeated with several different metals substituting for the lead. The masses of metal and water and the initial temperatures of the metal and water are the same as in Figure 7-3. The final temperatures are **(a)** Zn, 38.9 °C; **(b)** Pt, 28.8 °C; **(c)** Al, 52.7 °C. What is the specific heat of each metal, expressed in $\mathrm{J\,g^{-1}\,°C^{-1}}$?
4. A 75.0 g piece of Ag metal is heated to 80.0 °C and dropped into 50.0 g of water at 23.2 °C. The final temperature of the $Ag-H_2O$ mixture is 27.6 °C. What is the specific heat of silver?
5. A 465 g chunk of iron is removed from an oven and plunged into 375 g water in an insulated container. The temperature of the water increases from 26 to 87 °C. If the specific heat of iron is $0.449\ \mathrm{J\,g^{-1}\,°C^{-1}}$, what must have been the original temperature of the iron?
6. A piece of stainless steel (sp ht $= 0.50\ \mathrm{J\,g^{-1}\,°C^{-1}}$) is transferred from an oven at 183 °C into 125 mL of water at 23.2 °C. The water temperature rises to 51.5 °C. What is the mass of the steel? How precise is this method of mass determination? Explain.
7. A 1.00 kg sample of magnesium at 40.0 °C is added to 1.00 L of water maintained at 20.0 °C in an insulated container. What will be the final temperature of the $Mg-H_2O$ mixture (specific heat of Mg $= 1.024\ \mathrm{J\,g^{-1}\,°C^{-1}}$)?
8. Brass has a density of $8.40\ \mathrm{g/cm^3}$ and a specific heat of $0.385\ \mathrm{J\,g^{-1}\,°C^{-1}}$. A $15.2\ \mathrm{cm^3}$ piece of brass at an initial temperature of 163 °C is dropped into an insulated container with 150.0 g water initially at 22.4 °C. What will be the final temperature of the brass–water mixture?
9. A 74.8 g sample of copper at 143.2 °C is added to an insulated vessel containing 165 mL of glycerol, $C_3H_8O_3(l)$ ($d = 1.26\ \mathrm{g/mL}$), at 24.8 °C. The final temperature is 31.1°C. The specific heat of copper is $0.385\ \mathrm{J\,g^{-1}\,°C^{-1}}$. What is the heat capacity of glycerol in $\mathrm{J\,mol^{-1}\,°C^{-1}}$?
10. What volume of 18.5 °C water must be added, together with a 1.23 kg piece of iron at 68.5 °C, so that the temperature of the water in the insulated container shown in the figure remains constant at 25.6 °C?



11. In the form of heat, 6.052 J of energy is transferred to a 1.0 L sample of air ($d = 1.204\,\mathrm{mg/cm^3}$) at 20.0 °C. The final temperature of the air is 25.0 °C. What is the heat capacity of air in J/K?

12. What is the final temperature (in °C) of 1.24 g of water with an initial temperature of 20.0 °C after 6.052 J of heat is added to it?

Heats of Reaction

13. How much heat, in kilojoules, is associated with the production of 283 kg of slaked lime, $Ca(OH)_2$?

$$\mathrm{CaO(s) + H_2O(l) \longrightarrow Ca(OH)_2(s)} \qquad \Delta H° = -65.2\,\mathrm{kJ}$$

14. The standard enthalpy change in the combustion of the hydrocarbon octane is $\Delta H° = -5.48 \times 10^3$ kJ/mol $C_8H_{18}(l)$. How much heat, in kilojoules, is liberated *per gallon* of octane burned? (Density of octane = 0.703 g/mL; 1 gal = 3.785 L.)

15. How much heat, in kilojoules, is evolved in the complete combustion of **(a)** 1.325 g $C_4H_{10}(g)$ at 25 °C and 1 atm; **(b)** 28.4 L $C_4H_{10}(g)$ at STP; **(c)** 12.6 L $C_4H_{10}(g)$ at 23.6 °C and 738 mmHg? Assume that the enthalpy change for the reaction does not change significantly with temperature or pressure. The complete combustion of butane, $C_4H_{10}(g)$, is represented by the equation

$$\mathrm{C_4H_{10}(g) + \frac{13}{2}O_2(g) \longrightarrow 4\,CO_2(g) + 5\,H_2O(l)} \qquad \Delta H° = -2877\,\mathrm{kJ}$$

16. Upon complete combustion, the indicated substances evolve the given quantities of heat. Write a balanced equation for the combustion of 1.00 mol of each substance, including the enthalpy change, ΔH, for the reaction.

(a) 0.584 g of propane, $C_3H_8(g)$, yields 29.4 kJ

(b) 0.136 g of camphor, $C_{10}H_{16}O(s)$, yields 5.27 kJ

(c) 2.35 mL of acetone, $(CH_3)_2CO(l)$ ($d = 0.791$ g/mL), yields 58.3 kJ

17. The combustion of methane gas, the principal constituent of natural gas, is represented by the equation

$$\mathrm{CH_4(g) + 2\,O_2(g) \longrightarrow CO_2(g) + 2\,H_2O(l)} \qquad \Delta H° = -890.3\,\mathrm{kJ}$$

(a) What mass of methane, in kilograms, must be burned to liberate 2.80×10^7 kJ of heat?

(b) What quantity of heat, in kilojoules, is liberated in the complete combustion of 1.65×10^4 L of $CH_4(g)$, measured at 18.6 °C and 768 mmHg?

(c) If the quantity of heat calculated in part **(b)** could be transferred with 100% efficiency to water, what volume of water, in liters, could be heated from 8.8 to 60.0 °C as a result?

18. Refer to the Integrative Example. What volume of the synthesis gas, measured at STP and burned in an open flame (constant-pressure process), is required to heat 40.0 gal of water from 15.2 to 65.0 °C? (1 gal = 3.785 L.)

19. The combustion of hydrogen–oxygen mixtures is used to produce very high temperatures (approximately 2500 °C) needed for certain types of welding operations. Consider the reaction to be

$$\mathrm{H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(g)} \qquad \Delta H° = -241.8\,\mathrm{kJ}$$

What is the quantity of heat evolved, in kilojoules, when a 180 g mixture containing equal parts of H_2 and O_2 by mass is burned?

20. Thermite mixtures are used for certain types of welding, and the thermite reaction is highly exothermic.

$$\mathrm{Fe_2O_3(s) + 2\,Al(s) \longrightarrow Al_2O_3(s) + 2\,Fe(s)} \qquad \Delta H° = -852\,\mathrm{kJ}$$

1.00 mol of granular Fe_2O_3 and 2.00 mol of granular Al are mixed at room temperature (25 °C), and a reaction is initiated. The liberated heat is retained within the products, whose combined specific heat over a broad temperature range is about $0.8\,\mathrm{J\,g^{-1}\,°C^{-1}}$. (The melting point of iron is 1530 °C.) Show that the quantity of heat liberated is more than sufficient to raise the temperature of the products to the melting point of iron.

21. A 0.205 g pellet of potassium hydroxide, KOH, is added to 55.9 g water in a Styrofoam coffee cup. The water temperature rises from 23.5 to 24.4 °C. [Assume that the specific heat of dilute KOH(aq) is the same as that of water.]

(a) What is the approximate heat of solution of KOH, expressed as kilojoules per mole of KOH?

(b) How could the precision of this measurement be improved *without* modifying the apparatus?

22. The heat of solution of KI(s) in water is +20.3 kJ/mol KI. If a quantity of KI is added to sufficient water at 23.5 °C in a Styrofoam cup to produce 150.0 mL of 2.50 M KI, what will be the final temperature? (Assume a density of 1.30 g/mL and a specific heat of $2.7\,\mathrm{J\,g^{-1}\,°C^{-1}}$ for 2.50 M KI.)

23. You are planning a lecture demonstration to illustrate an endothermic process. You want to lower the temperature of 1400 mL water in an insulated container from 25 to 10 °C. Approximately what mass of $NH_4Cl(s)$ should you dissolve in the water to achieve this result? The heat of solution of NH_4Cl is +14.7 kJ/mol NH_4Cl.

24. Care must be taken in preparing solutions of solutes that liberate heat on dissolving. The heat of solution of NaOH is −44.5 kJ/mol NaOH. To what maximum temperature may a sample of water, originally at 21 °C, be raised in the preparation of 500 mL of 7.0 M NaOH? Assume the solution has a density of 1.08 g/mL and specific heat of $4.00\,\mathrm{J\,g^{-1}\,°C^{-1}}$.

25. Refer to Example 7-4. The product of the neutralization is 0.500 M NaCl. For this solution, assume a density of 1.02 g/mL and a specific heat of $4.02\,\mathrm{J\,g^{-1}\,°C^{-1}}$. Also, assume a heat capacity for the Styrofoam cup of 10 J/°C, and recalculate the heat of neutralization.

26. The heat of neutralization of HCl(aq) by NaOH(aq) is −55.84 kJ/mol H_2O produced. If 50.00 mL of 1.05 M NaOH is added to 25.00 mL of 1.86 M HCl, with both solutions originally at 24.72 °C, what will be the final solution temperature? (Assume that no heat is lost to the surrounding air and that the solution produced in the neutralization reaction has a density of 1.02 g/mL and a specific heat of $3.98\,\mathrm{J\,g^{-1}\,°C^{-1}}$.)

27. Acetylene (C_2H_2) torches are used in welding. How much heat (in kJ) evolves when 5.0 L of C_2H_2 ($d = 1.0967\ \text{kg/m}^3$) is mixed with a stoichiometric amount of oxygen gas? The combustion reaction is

$$C_2H_2(g) + \frac{5}{2}O_2(g) \longrightarrow 2\,CO_2(g) + H_2O(l) \qquad \Delta H^\circ = -1299.5\ \text{kJ}$$

28. Propane (C_3H_8) gas ($d = 1.83\ \text{kg/m}^3$) is used in most gas grills. What volume (in liters) of propane is needed to generate 273.8 kJ of heat?

$$C_3H_8(g) + 5\,O_2(g) \longrightarrow 3\,CO_2(g) + 4\,H_2O(l) \qquad \Delta H^\circ = -2219.9\ \text{kJ}$$

Enthalpy Changes and States of Matter

29. What mass of ice can be melted with the same quantity of heat as required to raise the temperature of 3.50 mol $H_2O(l)$ by 50.0 °C? [$\Delta H^\circ_{\text{fusion}} = 6.01$ kJ/mol $H_2O(s)$]

30. What will be the final temperature of the water in an insulated container as the result of passing 5.00 g of steam, $H_2O(g)$, at 100.0 °C into 100.0 g of water at 25.0 °C? ($\Delta H^\circ_{\text{vap}} = 40.6$ kJ/mol H_2O)

31. A 125 g stainless steel ball bearing (sp ht = $0.50\ \text{J g}^{-1}\,°\text{C}^{-1}$) at 525 °C is dropped into 75.0 mL of water at 28.5 °C in an open Styrofoam cup. As a result, the water is brought to a boil when the temperature reaches 100.0 °C. What mass of water vaporizes while the boiling continues? ($\Delta H^\circ_{\text{vap}} = 40.6$ kJ/mol H_2O)

32. If the ball bearing described in Exercise 31 is dropped onto a large block of ice at 0 °C, what mass of liquid water will form? ($\Delta H^\circ_{\text{fusion}} = 6.01$ kJ/mol $H_2O(s)$)

33. The enthalpy of sublimation (solid → gas) for dry ice (i.e., CO_2) is $\Delta H^\circ_{\text{sub}} = 571$ kJ/kg at −78.5 °C. If 125.0 J of heat is transferred to a block of dry ice that is −78.5°C, what volume of CO_2 gas ($d = 1.98$ g/L) will be generated?

34. The enthalpy of vaporization for $N_2(l)$ is 5.56 kJ/ mol. How much heat (in J) is required to produce 1.0 L of $N_2(g)$ at 77.36 K and 1.0 atm?

Calorimetry

35. A sample gives off 5228 cal when burned in a bomb calorimeter. The temperature of the calorimeter assembly increases by 4.39 °C. Calculate the heat capacity of the calorimeter, in kilojoules per degree Celsius.

36. The following substances undergo complete combustion in a bomb calorimeter. The calorimeter assembly has a heat capacity of 5.136 kJ/°C. In each case, what is the final temperature if the initial water temperature is 22.43 °C?
(a) 0.3268 g caffeine, $C_8H_{10}O_2N_4$ (heat of combustion = −1014.2 kcal/mol caffeine);
(b) 1.35 mL of methyl ethyl ketone, $C_4H_8O(l)$, $d = 0.805$ g/mL (heat of combustion = −2444 kJ/mol methyl ethyl ketone).

37. A bomb calorimetry experiment is performed with xylose, $C_5H_{10}O_5(s)$, as the combustible substance. The data obtained are

mass of xylose burned:	1.183 g
heat capacity of calorimeter:	4.728 kJ/°C
initial calorimeter temperature:	23.29 °C
final calorimeter temperature:	27.19 °C

(a) What is the heat of combustion of xylose, in kilojoules per mole? **(b)** Write the chemical equation for the complete combustion of xylose, and represent the value of ΔH in this equation. (Assume for this reaction that $\Delta U \approx \Delta H$.)

38. A coffee-cup calorimeter contains 100.0 mL of 0.300 M HCl at 20.3 °C. When 1.82 g Zn(s) is added, the temperature rises to 30.5 °C. What is the heat of reaction per mol Zn? Make the same assumptions as in Example 7-4, and also assume that there is no heat lost with the $H_2(g)$ that escapes.

$$Zn(s) + 2\,H^+(aq) \longrightarrow Zn^{2+}(aq) + H_2(g)$$

39. A 0.75 g sample of KCl is added to 35.0 g H_2O in a Styrofoam cup and stirred until it dissolves. The temperature of the solution drops from 24.8 to 23.6 °C. **(a)** Is the process endothermic or exothermic? **(b)** What is the heat of solution of KCl expressed in kilojoules per mole of KCl?

40. The heat of solution of potassium acetate in water is −15.3 kJ/mol $KC_2H_3O_2$. What will be the final temperature when 0.136 mol $KC_2H_3O_2$ is dissolved in 525 mL water that is initially at 25.1 °C?

41. A 1.620 g sample of naphthalene, $C_{10}H_8(s)$, is completely burned in a bomb calorimeter assembly and a temperature increase of 8.44 °C is noted. If the heat of combustion of naphthalene is −5156 kJ/mol $C_{10}H_8$, what is the heat capacity of the bomb calorimeter?

42. Salicylic acid, $C_7H_6O_3$, has been suggested as a calorimetric standard. Its heat of combustion is -3.023×10^3 kJ/mol $C_7H_6O_3$. From the following data determine the heat capacity of a bomb calorimeter assembly (that is, the bomb, water, stirrer, thermometer, wires, and so forth).

mass of salicylic acid burned:	1.201 g
initial calorimeter temperature:	23.68 °C
final calorimeter temperature:	29.82 °C

43. Refer to Example 7-3. Based on the heat of combustion of sucrose established in the example, what should be the temperature change (ΔT) produced by the combustion of 1.227 g $C_{12}H_{22}O_{11}$ in a bomb calorimeter assembly with a heat capacity of 3.87 kJ/°C?

44. A 1.397 g sample of thymol, $C_{10}H_{14}O(s)$ (a preservative and a mold and mildew preventative), is burned in a bomb calorimeter assembly. The temperature increase is 11.23 °C, and the heat capacity of the bomb calorimeter is 4.68 kJ/°C. What is the heat of combustion of thymol, expressed in kilojoules per mole of $C_{10}H_{14}O$?

45. A 5.0 g sample of NaCl is added to a Styrofoam cup of water, and the change in water temperature is 5.0 °C. The heat of solution of NaCl is 3.76 kJ/ mol. What is the mass (in g) of water in the Styrofoam cup?

46. We can determine the purity of solid materials by using calorimetry. A gold ring (for pure gold, specific heat $= 0.1291\ \mathrm{J\,g^{-1}\,K^{-1}}$) with mass of 10.5 g is heated to 78.3 °C and immersed in 50.0 g of 23.7 °C water in a constant-pressure calorimeter. The final temperature of the water is 31.0 °C. Is this a pure sample of gold?

Pressure–Volume Work

47. Calculate the quantity of work associated with a 3.5 L expansion of a gas (ΔV) against a pressure of 748 mmHg in the units **(a)** atm L; **(b)** joules (J); **(c)** calories (cal).

48. Calculate the quantity of work, in joules, associated with the compression of a gas from 5.62 L to 3.37 L by a constant pressure of 1.23 atm.

49. A 1.00 g sample of Ne(g) at 1 atm pressure and 27 °C is allowed to expand into an *evacuated* vessel of 2.50 L volume. Does the gas do work? Explain.

50. Compressed air in aerosol cans is used to free electronic equipment of dust. Does the air do any work as it escapes from the can?

51. In each of the following processes, is any work done when the reaction is carried out at constant pressure in a vessel open to the atmosphere? If so, is work done by the reacting system or on it? **(a)** Neutralization of $Ba(OH)_2(aq)$ by HCl(aq); **(b)** conversion of gaseous nitrogen dioxide to gaseous dinitrogen tetroxide; **(c)** decomposition of calcium carbonate to calcium oxide and carbon dioxide gas.

52. In each of the following processes, is any work done when the reaction is carried out at constant pressure in a vessel open to the atmosphere? If so, is work done by the reacting system or on it? **(a)** Reaction of nitrogen monoxide and oxygen gases to form gaseous nitrogen dioxide; **(b)** precipitation of magnesium hydroxide by the reaction of aqueous solutions of NaOH and $MgCl_2$; **(c)** reaction of copper(II) sulfate and water vapor to form copper(II) sulfate pentahydrate.

53. If 325 J of work is done by a system at a pressure of 1.0 atm and 298 K, what is the change in the volume of the system?

54. A movable piston in a cylinder holding 5.0 L $N_2(g)$ is used to lift a 1.23 kg object to a height of 4.5 meters. How much work (in J) was done by the gas?

First Law of Thermodynamics

55. What is the change in internal energy of a system if the system **(a)** absorbs 58 J of heat and does 58 J of work; **(b)** absorbs 125 J of heat and does 687 J of work; **(c)** evolves 280 cal of heat and has 1.25 kJ of work done on it?

56. What is the change in internal energy of a system if the *surroundings* **(a)** transfer 235 J of heat and 128 J of work to the system; **(b)** absorb 145 J of heat from the system while doing 98 J of work on the system; **(c)** exchange no heat, but receive 1.07 kJ of work from the system?

57. The internal energy of a fixed quantity of an ideal gas depends only on its temperature. A sample of an ideal gas is allowed to expand at a constant temperature (isothermal expansion). **(a)** Does the gas do work? **(b)** Does the gas exchange heat with its surroundings? **(c)** What happens to the temperature of the gas? **(d)** What is ΔU for the gas?

58. In an *adiabatic* process, a system is thermally insulated—there is no exchange of heat between system and surroundings. For the adiabatic expansion of an ideal gas **(a)** does the gas do work? **(b)** Does the internal energy of the gas increase, decrease, or remain constant? **(c)** What happens to the temperature of the gas? [*Hint*: Refer to Exercise 57.]

59. Do you think the following observation is in any way possible? An ideal gas is expanded isothermally and is observed to do twice as much work as the heat absorbed from its surroundings. Explain your answer. [*Hint:* Refer to Exercises 57 and 58.]

60. Do you think the following observation is any way possible? A gas absorbs heat from its surroundings while being compressed. Explain your answer. [*Hint:* Refer to Exercises 55 and 56.]

61. There are other forms of work besides P–V work. For example, electrical work is defined as the potential × change in charge, $w = \phi\, dq$. If a charge in a system is changed from 10 C to 5 C in a potential of 100 V and 45 J of heat is liberated, what is the change in the internal energy? (Note: 1 V = 1 J/C)

62. Another form of work is extension, defined as the tension × change in length, $w = f\,\Delta l$. A piece of DNA has an approximate tension of $f = 10$ pN. What is the change in the internal energy of the adiabatic stretching of DNA by 10 pm?

Relating ΔH and ΔU

63. Only one of the following expressions holds true for the heat of a chemical reaction, *regardless of how the reaction is carried out.* Which is the correct expression and why? **(a)** q_V; **(b)** q_P; **(c)** $\Delta U - w$; **(d)** ΔU; **(e)** ΔH.

64. Determine whether ΔH is equal to, greater than, or less than ΔU for the following reactions. Keep in mind that "greater than" means more positive or less negative, and "less than" means less positive or more negative. Assume that the only significant change in volume during a reaction at constant pressure is that associated with changes in the amounts of gases.

(a) The complete combustion of one mole of 1-butanol(l).

(b) The complete combustion of one mole of glucose, $C_6H_{12}O_6(s)$.

(c) The decomposition of solid ammonium nitrate to produce liquid water and gaseous dinitrogen monoxide.

65. The heat of combustion of 2-propanol at 298.15 K, determined in a bomb calorimeter, is $-33.41\ \text{kJ/g}$. For the combustion of one mole of 2-propanol, determine **(a)** ΔU, and **(b)** ΔH.

66. Write an equation to represent the combustion of thymol referred to in Exercise 44. Include in this equation the values for ΔU and ΔH.

Hess's Law

67. The standard enthalpy of formation of $NH_3(g)$ is $-46.11\ \text{kJ/mol}\ NH_3$. What is ΔH° for the following reaction?

$$\frac{2}{3}NH_3(g) \longrightarrow \frac{1}{3}N_2(g) + H_2(g) \qquad \Delta H^\circ =$$

68. Use Hess's law to determine ΔH° for the reaction $CO(g) + \frac{1}{2}O_2(g) \longrightarrow CO_2(g)$, given that

$$C(\text{graphite}) + \frac{1}{2}O_2(g) \longrightarrow CO(g) \qquad \Delta H^\circ = -110.54\ \text{kJ}$$

$$C(\text{graphite}) + O_2(g) \longrightarrow CO_2(g) \qquad \Delta H^\circ = -393.51\ \text{kJ}$$

69. Use Hess's law to determine ΔH° for the reaction $C_3H_4(g) + 2\,H_2(g) \longrightarrow C_3H_8(g)$, given that

$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l) \qquad \Delta H^\circ = -285.8\ \text{kJ}$$

$$C_3H_4(g) + 4\,O_2(g) \longrightarrow 3\,CO_2(g) + 2\,H_2O(l) \qquad \Delta H^\circ = -1937\ \text{kJ}$$

$$C_3H_8(g) + 5\,O_2(g) \longrightarrow 3\,CO_2(g) + 4\,H_2O(l) \qquad \Delta H^\circ = -2219.1\ \text{kJ}$$

70. Given the following information:

$$\frac{1}{2}N_2(g) + \frac{3}{2}H_2(g) \longrightarrow NH_3(g) \qquad \Delta H^\circ_1$$

$$NH_3(g) + \frac{5}{4}O_2(g) \longrightarrow NO(g) + \frac{3}{2}H_2O(l) \qquad \Delta H^\circ_2$$

$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l) \qquad \Delta H^\circ_3$$

Determine ΔH° for the following reaction, expressed in terms of ΔH°_1, ΔH°_2, and ΔH°_3.

$$N_2(g) + O_2(g) \longrightarrow 2\,NO(g) \qquad \Delta H^\circ = ?$$

71. For the reaction $C_2H_4(g) + Cl_2(g) \longrightarrow C_2H_4Cl_2(l)$, determine ΔH°, given that

$$4\,HCl(g) + O_2(g) \longrightarrow 2\,Cl_2(g) + 2\,H_2O(l) \qquad \Delta H^\circ = -202.4\ \text{kJ}$$

$$2\,HCl(g) + C_2H_4(g) + \frac{1}{2}O_2(g) \longrightarrow C_2H_4Cl_2(l) + H_2O(l) \qquad \Delta H^\circ = -318.7\ \text{kJ}$$

72. Determine ΔH° for this reaction from the data below.
$N_2H_4(l) + 2\,H_2O_2(l) \longrightarrow N_2(g) + 4\,H_2O(l)$

$$N_2H_4(l) + O_2(g) \longrightarrow N_2(g) + 2\,H_2O(l) \qquad \Delta H^\circ = -622.2\ \text{kJ}$$

$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l) \qquad \Delta H^\circ = -285.8\ \text{kJ}$$

$$H_2(g) + O_2(g) \longrightarrow H_2O_2(l) \qquad \Delta H^\circ = -187.8\ \text{kJ}$$

73. Substitute natural gas (SNG) is a gaseous mixture containing $CH_4(g)$ that can be used as a fuel. One reaction for the production of SNG is

$$4\,CO(g) + 8\,H_2(g) \longrightarrow 3\,CH_4(g) + CO_2(g) + 2\,H_2O(l) \qquad \Delta H^\circ = ?$$

Use appropriate data from the following list to determine ΔH° for this SNG reaction.

$$C(\text{graphite}) + \frac{1}{2}O_2(g) \longrightarrow CO(g) \qquad \Delta H^\circ = -110.5\ \text{kJ}$$

$$CO(g) + \frac{1}{2}O_2(g) \longrightarrow CO_2(g) \qquad \Delta H^\circ = -283.0\ \text{kJ}$$

$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l) \qquad \Delta H^\circ = -285.8\ \text{kJ}$$

$$C(\text{graphite}) + 2\,H_2(g) \longrightarrow CH_4(g) \qquad \Delta H^\circ = -74.81\ \text{kJ}$$

$$CH_4(g) + 2\,O_2(g) \longrightarrow CO_2(g) + 2\,H_2O(l) \qquad \Delta H^\circ = -890.3\ \text{kJ}$$

74. CCl_4, an important commercial solvent, is prepared by the reaction of $Cl_2(g)$ with a carbon compound. Determine ΔH° for the reaction

$$CS_2(l) + 3\,Cl_2(g) \longrightarrow CCl_4(l) + S_2Cl_2(l).$$

Use appropriate data from the following listing.

$$CS_2(l) + 3\,O_2(g) \longrightarrow CO_2(g) + 2\,SO_2(g) \qquad \Delta H^\circ = -1077\ \text{kJ}$$

$$2\,S(s) + Cl_2(g) \longrightarrow S_2Cl_2(l) \qquad \Delta H^\circ = -58.2\ \text{kJ}$$

$$C(s) + 2\,Cl_2(g) \longrightarrow CCl_4(l) \qquad \Delta H^\circ = -135.4\ \text{kJ}$$

$$S(s) + O_2(g) \longrightarrow SO_2(g) \qquad \Delta H^\circ = -296.8\ \text{kJ}$$

$$SO_2(g) + Cl_2(g) \longrightarrow SO_2Cl_2(l) \qquad \Delta H^\circ = +97.3\ \text{kJ}$$

$$C(s) + O_2(g) \longrightarrow CO_2(g) \qquad \Delta H^\circ = -393.5\ \text{kJ}$$

$$CCl_4(l) + O_2(g) \longrightarrow COCl_2(g) + Cl_2O(g) \qquad \Delta H^\circ = -5.2\ \text{kJ}$$

75. Use Hess's law and the following data

$$CH_4(g) + 2\,O_2(g) \longrightarrow CO_2(g) + 2\,H_2O(g) \qquad \Delta H^\circ = -802\ \text{kJ}$$

$$CH_4(g) + CO_2(g) \longrightarrow 2\,CO(g) + 2\,H_2(g) \qquad \Delta H^\circ = +247\ \text{kJ}$$

$$CH_4(g) + H_2O(g) \longrightarrow CO(g) + 3\,H_2(g) \qquad \Delta H^\circ = +206\ \text{kJ}$$

to determine ΔH° for the following reaction, an important source of hydrogen gas

$$CH_4(g) + \frac{1}{2}O_2(g) \longrightarrow CO(g) + 2\,H_2(g)$$

76. The standard heats of combustion ($\Delta H°$) per mole of 1,3-butadiene, $C_4H_6(g)$; butane, $C_4H_{10}(g)$; and $H_2(g)$ are −2540.2, −2877.6, and −285.8 kJ, respectively. Use these data to calculate the heat of hydrogenation of 1,3-butadiene to butane.

$$C_4H_6(g) + 2\,H_2(g) \longrightarrow C_4H_{10}(g) \qquad \Delta H° = ?$$

[*Hint:* Write equations for the combustion reactions. In each combustion, the products are $CO_2(g)$ and $H_2O(l)$.]

77. One glucose molecule, $C_6H_{12}O_6(s)$, is converted to two lactic acid molecules, $CH_3CH(OH)COOH(s)$ during glycolysis. Given the combustion reactions of glucose and lactic acid, determine the standard enthalpy for glycolysis.

$$C_6H_{12}O_6(s) + 6\,O_2(g) \longrightarrow 6\,CO_2(g) + 6\,H_2O(l) \qquad \Delta H° = -2808\text{ kJ}$$

$$CH_3CH(OH)COOH(s) + 3\,O_2(g) \longrightarrow 3\,CO_2(g) + 3\,H_2O(l) \qquad \Delta H° = -1344\text{ kJ}$$

78. The standard enthalpy of fermentation of glucose to ethanol is

$$C_6H_{12}O_6(s) \rightarrow 2\,CH_3CH_2OH(l) + 2\,CO_2(g) \qquad \Delta H° = -72\text{ kJ}$$

Use the standard enthalpy of combustion for glucose to calculate the enthalpy of combustion for ethanol.

Standard Enthalpies of Formation

79. Use standard enthalpies of formation from Table 7.2 and equation (7.21) to determine the standard enthalpy changes in the following reactions.
(a) $C_3H_8(g) + H_2(g) \longrightarrow C_2H_6(g) + CH_4(g)$;
(b) $2\,H_2S(g) + 3\,O_2(g) \longrightarrow 2\,SO_2(g) + 2\,H_2O(l)$.

80. Use standard enthalpies of formation from Tables 7.2 and 7.3 and equation (7.21) to determine the standard enthalpy change in the following reaction.

$$NH_4{}^+(aq) + OH^-(aq) \longrightarrow H_2O(l) + NH_3(g).$$

81. Use the information given here, data from Appendix D, and equation (7.21) to calculate the standard enthalpy of formation per mole of ZnS(s).

$$2\,ZnS(s) + 3\,O_2(g) \longrightarrow 2\,ZnO(s) + 2\,SO_2(g) \qquad \Delta H° = -878.2\text{ kJ}$$

82. Use the data in Figure 7-18 and information from Section 3-7 to establish possible relationships between the molecular structure of the hydrocarbons and their standard enthalpies of formation.

83. Use standard enthalpies of formation from Table 7.2 to determine the enthalpy change at 25 °C for the following reaction.

$$2\,Cl_2(g) + 2\,H_2O(l) \longrightarrow 4\,HCl(g) + O_2(g) \qquad \Delta H° = ?$$

84. Use data from Appendix D to calculate the standard enthalpy change for the following reaction at 25 °C.

$$Fe_2O_3(s) + 3\,CO(g) \longrightarrow 2\,Fe(s) + 3\,CO_2(g) \qquad \Delta H° = ?$$

85. Use data from Table 7.2 to determine the standard heat of combustion of $C_2H_5OH(l)$, if reactants and products are maintained at 25 °C and 1 bar.

86. Use data from Table 7.2, together with the fact that $\Delta H° = -3509$ kJ for the complete combustion of one mole of pentane, $C_5H_{12}(l)$, to calculate $\Delta H°$ for the synthesis of 1 mol $C_5H_{12}(l)$ from CO(g) and $H_2(g)$.

$$5\,CO(g) + 11\,H_2(g) \longrightarrow C_5H_{12}(l) + 5\,H_2O(l) \qquad \Delta H° = ?$$

87. Use data from Table 7.2 and $\Delta H°$ for the following reaction to determine the standard enthalpy of formation of $CCl_4(g)$ at 25 °C and 1 bar.

$$CH_4(g) + 4\,Cl_2(g) \longrightarrow CCl_4(g) + 4\,HCl(g) \qquad \Delta H° = -397.3\text{ kJ}$$

88. Use data from Table 7.2 and $\Delta H°$ for the following reaction to determine the standard enthalpy of formation of hexane, $C_6H_{14}(l)$, at 25 °C and 1 bar.

$$2\,C_6H_{14}(l) + 19\,O_2(g) \longrightarrow 12\,CO_2(g) + 14\,H_2O(l) \qquad \Delta H° = -8326\text{ kJ}$$

89. Use data from Table 7.3 and Appendix D to determine the standard enthalpy change in the following reaction.

$$Al^{3+}(aq) + 3\,OH^-(aq) \longrightarrow Al(OH)_3(s) \qquad \Delta H° = ?$$

90. Use data from Table 7.3 and Appendix D to determine the standard enthalpy change in the following reaction.

$$Mg(OH)_2(s) + 2\,NH_4{}^+(aq) \longrightarrow Mg^{2+}(aq) + 2\,H_2O(l) + 2\,NH_3(g) \qquad \Delta H° = ?$$

91. The decomposition of limestone, $CaCO_3(s)$, into quicklime, CaO(s), and $CO_2(g)$ is carried out in a gas-fired kiln. Use data from Appendix D to determine how much heat is required to decompose 1.35×10^3 kg $CaCO_3(s)$. (Assume that heats of reaction are the same as at 25 °C and 1 bar.)

92. Use data from Table 7.2 to calculate the volume of butane, $C_4H_{10}(g)$, measured at 24.6 °C and 756 mmHg, that must be burned to liberate 5.00×10^4 kJ of heat.

93. Ants release formic acid (HCOOH) when they bite. Use the data in Table 7.2 and the standard enthalpy of combustion for formic acid ($\Delta H° = -255$ kJ/mol) to calculate the standard enthalpy of formation for formic acid.

94. Calculate the enthalpy of combustion for lactic acid by using the data in Table 7.2 and the standard enthalpy of formation for lactic acid [$CH_3CH(OH)COOH(s)$]: $\Delta H_f° = -694.0$ kJ/mol.

Integrative and Advanced Exercises

95. A British thermal unit (Btu) is defined as the quantity of heat required to change the temperature of 1 lb of water by 1 °F. Assume the specific heat of water to be independent of temperature. How much heat is required to raise the temperature of the water in a 40 gal water heater from 48 to 145 °F in **(a)** Btu; **(b)** kcal; **(c)** kJ?

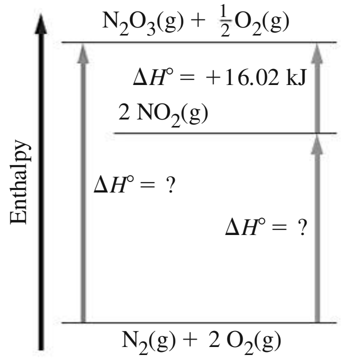
96. A 7.26 kg shot (as used in the sporting event, the shot put) is dropped from the top of a building 168 m high. What is the maximum temperature increase that could occur in the shot? Assume a specific heat of $0.47\ \text{J g}^{-1}\,°\text{C}^{-1}$ for the shot. Why would the actual measured temperature increase likely be less than the calculated value?

97. An alternative approach to bomb calorimetry is to establish the heat capacity of the calorimeter, *exclusive* of the water it contains. The heat absorbed by the water and by the rest of the calorimeter must be calculated separately and then added together. A bomb calorimeter assembly containing 983.5 g water is calibrated by the combustion of 1.354 g anthracene. The temperature of the calorimeter rises from 24.87 to 35.63 °C. When 1.053 g citric acid is burned in the same assembly, but with 968.6 g water, the temperature increases from 25.01 to 27.19 °C. The heat of combustion of anthracene, $C_{14}H_{10}(s)$, is -7067 kJ/mol $C_{14}H_{10}$. What is the heat of combustion of citric acid, $C_6H_8O_7$, expressed in kJ/mol?

98. The method of Exercise 97 is used in some bomb calorimetry experiments. A 1.148 g sample of benzoic acid is burned in excess $O_2(g)$ in a bomb immersed in 1181 g of water. The temperature of the water rises from 24.96 to 30.25 °C. The heat of combustion of benzoic acid is -26.42 kJ/g. In a second experiment, a 0.895 g powdered coal sample is burned in the same calorimeter assembly. The temperature of 1162 g of water rises from 24.98 to 29.81 °C. How many metric tons (1 metric ton $=$ 1000 kg) of this coal would have to be burned to release 2.15×10^9 kJ of heat?

99. A handbook lists two different values for the heat of combustion of hydrogen: 33.88 kcal/g H_2 if $H_2O(l)$ is formed, and 28.67 kcal/g H_2 if $H_2O(g)$ is formed. Explain why these two values are different, and indicate what property this difference represents. Devise a means of verifying your conclusions.

100. Determine the missing values of $\Delta H°$ in the diagram shown below.



101. A particular natural gas consists, in mole percents, of 83.0% CH_4, 11.2% C_2H_6, and 5.8% C_3H_8. A 385 L sample of this gas, measured at 22.6 °C and 739 mmHg, is burned at constant pressure in an excess of oxygen gas. How much heat, in kilojoules, is evolved in the combustion reaction?

102. An overall reaction for a coal gasification process is

$$2\,C(\text{graphite}) + 2\,H_2O(g) \longrightarrow CH_4(g) + CO_2(g)$$

Show that this overall equation can be established by an appropriate combination of equations from Section 7-9.

103. Which of the following gases has the greater fuel value on a per liter (STP) basis? That is, which has the greater heat of combustion? [*Hint:* The only combustible gases are CH_4, C_3H_8, CO, and H_2.]
(a) coal gas: 49.7% H_2, 29.9% CH_4, 8.2% N_2, 6.9% CO, 3.1% C_3H_8, 1.7% CO_2, and 0.5% O_2, by volume.
(b) sewage gas, 66.0% CH_4, 30.0% CO_2, and 4.0% N_2, by volume.

104. A calorimeter that measures an exothermic heat of reaction by the quantity of ice that can be melted is called an ice calorimeter. Now consider that 0.100 L of methane gas, $CH_4(g)$, at 25.0 °C and 744 mmHg is burned at constant pressure in air. The heat liberated is captured and used to melt 9.53 g ice at 0 °C (ΔH_{fusion} of ice $=$ 6.01 kJ/mol).
(a) Write an equation for the complete combustion of CH_4, and show that combustion is incomplete in this case.
(b) Assume that CO(g) is produced in the incomplete combustion of CH_4, and represent the combustion as best you can through a single equation with small whole numbers as coefficients. ($H_2O(l)$ is another product of the combustion.)

105. For the reaction

$$C_2H_4(g) + 3\,O_2(g) \longrightarrow 2\,CO_2(g) + 2\,H_2O(l) \qquad \Delta H° = -1410.9\ \text{kJ}$$

if the H_2O were obtained as a gas rather than a liquid, **(a)** would the heat of reaction be greater (more negative) or smaller (less negative) than that indicated in the equation? **(b)** Explain your answer. **(c)** Calculate the value of $\Delta H°$ in this case.

106. Some of the butane, $C_4H_{10}(g)$, in a 200.0 L cylinder at 26.0 °C is withdrawn and burned at a constant pressure in an excess of air. As a result, the pressure of the gas in the cylinder falls from 2.35 atm to 1.10 atm. The liberated heat is used to raise the temperature of 132.5 L of water in a heater from 26.0 to 62.2 °C. Assume that the combustion products are $CO_2(g)$ and $H_2O(l)$ exclusively, and determine the efficiency of the water heater. (That is, what percent of the heat of combustion was absorbed by the water?)

107. The metabolism of glucose, $C_6H_{12}O_6$, yields $CO_2(g)$ and $H_2O(l)$ as products. Heat released in the process is converted to useful work with about 70% efficiency. Calculate the mass of glucose metabolized by a 58.0 kg person in climbing a mountain with an elevation gain of 1450 m. Assume that the work performed in the climb is about four times that required to simply lift 58.0 kg by 1450 m. (ΔH_f° of $C_6H_{12}O_6(s)$ is -1273.3 kJ/mol.)

108. An alkane hydrocarbon has the formula C_nH_{2n+2}. The enthalpies of formation of the alkanes decrease (become more negative) as the number of C atoms increases. Starting with butane, $C_4H_{10}(g)$, for each additional CH_2 group in the formula, the enthalpy of formation, ΔH_f°, changes by about -21 kJ/mol. Use this fact and data from Table 7.2 to estimate the heat of combustion of heptane, $C_7H_{16}(l)$.

109. Upon complete combustion, a 1.00 L sample (at STP) of a natural gas gives off 43.6 kJ of heat. If the gas is a mixture of $CH_4(g)$ and $C_2H_6(g)$, what is its percent composition, *by volume*?

110. Under the entry H_2SO_4, a reference source lists many values for the standard enthalpy of formation. For example, for pure $H_2SO_4(l)$, $\Delta H_f^\circ = -814.0$ kJ/mol; for a solution with 1 mol H_2O per mole of H_2SO_4, -841.8; with 10 mol H_2O, -880.5; with 50 mol H_2O; -886.8; with 100 mol H_2O, -887.7; with 500 mol H_2O, -890.5; with 1000 mol H_2O, -892.3; with 10,000 mol H_2O, -900.8; and with 100,000 mol H_2O, -907.3.
(a) Explain why these values are not all the same.
(b) The value of $\Delta H_f^\circ[H_2SO_4(aq)]$ in an infinitely dilute solution is -909.3 kJ/mol. What data from this chapter can you cite to confirm this value? Explain.
(c) If 500.0 mL of 1.00 M $H_2SO_4(aq)$ is prepared from pure $H_2SO_4(l)$, what is the approximate change in temperature that should be observed? Assume that the $H_2SO_4(l)$ and $H_2O(l)$ are at the same temperature initially and that the specific heat of the $H_2SO_4(aq)$ is about $4.2\ \mathrm{J\,g^{-1}\,{}^\circ C^{-1}}$.

111. Refer to the discussion of the gasification of coal (page 278), and show that some of the heat required in the gasification reaction (equation 7.24) can be supplied by the *methanation* reaction. This fact contributes to the success of modern processes that produce *synthetic natural gas* (SNG).

112. A 1.103 g sample of a gaseous carbon–hydrogen–oxygen compound that occupies a volume of 582 mL at 765.5 Torr and 25.00 °C is burned in an excess of $O_2(g)$ in a bomb calorimeter. The products of the combustion are 2.108 g $CO_2(g)$, 1.294 g $H_2O(l)$, and enough heat to raise the temperature of the calorimeter assembly from 25.00 to 31.94 °C. The heat capacity of the calorimeter is 5.015 kJ/°C. Write an equation for the combustion reaction, and indicate ΔH° for this reaction at 25.00 °C.

113. Several factors are involved in determining the cooking times required for foods in a microwave oven. One of these factors is specific heat. Determine the approximate time required to warm 250 mL of chicken broth from 4 °C (a typical refrigerator temperature) to 50 °C in a 700 W microwave oven. Assume that the density of chicken broth is about 1 g/mL and that its specific heat is approximately $4.2\ \mathrm{J\,g^{-1}\,{}^\circ C^{-1}}$.

114. Suppose you have a setup similar to the one depicted in Figure 7-8 except that there are two different weights rather than two equal weights. One weight is a steel cylinder 10.00 cm in diameter and 25 cm long, the other weight produces a pressure of 745 Torr. The temperature of the gas in the cylinder in which the expansion takes place is 25.0 °C. The piston restraining the gas has a diameter of 12.00 cm, and the height of the piston above the base of the gas expansion cylinder is 8.10 cm. The density of the steel is $7.75\ \mathrm{g/cm^3}$. How much work is done when the steel cylinder is suddenly removed from the piston?

115. When one mole of sodium carbonate decahydrate (washing soda) is gently warmed, 155.3 kJ of heat is absorbed, water vapor is formed, and sodium carbonate heptahydrate remains. On more vigorous heating, the heptahydrate absorbs 320.1 kJ of heat and loses more water vapor to give the monohydrate. Continued heating gives the anhydrous salt (soda ash) while 57.3 kJ of heat is absorbed. Calculate ΔH for the conversion of one mole of washing soda into soda ash. Estimate ΔU for this process. Why is the value of ΔU only an estimate?

116. The oxidation of $NH_3(g)$ to $NO(g)$ in the Ostwald process must be very carefully controlled in terms of temperature, pressure, and contact time with the catalyst. This is because the oxidation of $NH_3(g)$ can yield any one of the products $N_2(g)$, $N_2O(g)$, $NO(g)$, and $NO_2(g)$, depending on conditions. Show that oxidation of $NH_3(g)$ to $N_2(g)$ is the most exothermic of the four possible reactions.

117. In the Are You Wondering 7-1 box, the temperature variation of enthalpy is discussed, and the equation $q_P = \text{heat capacity} \times \text{temperature change} = C_P \times \Delta T$ was introduced to show how enthalpy changes with temperature for a constant-pressure process. Strictly speaking, the heat capacity of a substance at constant pressure is the slope of the line representing the variation of enthalpy (H) with temperature, that is

$$C_P = \frac{dH}{dT} \qquad \text{(at constant pressure)}$$

where C_P is the heat capacity of the substance in question. Heat capacity is an extensive quantity and heat capacities are usually quoted as molar heat capacities $C_{P,\mathrm{m}}$, the heat capacity of one mole of substance; an intensive property. The heat capacity at constant pressure is used to estimate the change in enthalpy due to a change in temperature. For infinitesimal changes in temperature,

$$dH = C_P dT \qquad \text{(at constant pressure)}$$

To evaluate the change in enthalpy for a particular temperature change, from T_1 to T_2, we write

$$\int_{H(T_1)}^{H(T_2)} dH = H(T_2) - H(T_1) = \int_{T_1}^{T_2} C_P dT$$

If we assume that C_P is independent of temperature, then we recover equation (7.5)

$$\Delta H = C_P \times \Delta T$$

On the other hand, we often find that the heat capacity is a function of temperature; a convenient empirical expression is

$$C_{P,\mathrm{m}} = a + bT + \frac{c}{T^2}$$

What is the change in molar enthalpy of N_2 when it is heated from 25.0 °C to 100.0 °C? The molar heat capacity of nitrogen is given by

$$C_{P,\mathrm{m}} = 28.58 + 3.77 \times 10^{-3}\,T - \frac{0.5 \times 10^5}{T^2}\,\mathrm{J\,K^{-1}\,mol^{-1}}$$

118. How much heat is required to convert 10.0 g of ice at −5.0 °C to steam at 100.0 °C? The temperature-dependent constant-pressure specific heat of ice is $C_p(T)/(\mathrm{kJ\,kg^{-1}\,K^{-1}}) = 1.0187T - 1.49 \times 10^{-2}$. The temperature-dependent constant-pressure specific heat for water is $C_p(T)/(\mathrm{kJ\,kg^{-1}\,K^{-1}}) = -1.0 \times 10^{-7}T^3 + 1.0 \times 10^{-4}T^2 - 3.92 \times 10^{-2}T + 8.7854$.

119. The standard enthalpy of formation of gaseous H_2O at 298.15 K is $-241.82\,\mathrm{kJ\,mol^{-1}}$. Using the ideas contained in Figure 7-16, estimate its value at 100.0 °C given the following values of the molar heat capacities at constant pressure: $H_2O(g)$: $33.58\,\mathrm{J\,K^{-1}\,mol^{-1}}$; $H_2(g)$: $28.84\,\mathrm{J\,K^{-1}\,mol^{-1}}$; $O_2(g)$: $29.37\,\mathrm{J\,K^{-1}\,mol^{-1}}$. Assume the heat capacities are independent of temperature.

Feature Problems

120. James Joule published his definitive work related to the first law of thermodynamics in 1850. He stated that "the quantity of heat capable of increasing the temperature of one pound of water by 1 °F requires for its evolution the expenditure of a mechanical force represented by the fall of 772 lb through the space of one foot." Validate this statement by relating it to information given in this text.

121. Based on specific heat measurements, Pierre Dulong and Alexis Petit proposed in 1818 that the specific heat of an element is inversely related to its atomic weight (atomic mass). Thus, by measuring the specific heat of a new element, its atomic weight could be readily established.

(a) Use data from Table 7.1 and inside the front cover to plot a *straight-line* graph relating atomic mass and specific heat. Write the equation for this straight line.

(b) Use the measured specific heat of $0.23\,\mathrm{J\,g^{-1}\,°C^{-1}}$ and the equation derived in part **(a)** to obtain an approximate value of the atomic mass of cadmium, an element discovered in 1817.

(c) To raise the temperature of 75.0 g of a particular metal by 15 °C requires 450 J of heat. What might this metal be?

122. We can use the heat liberated by a neutralization reaction as a means of establishing the stoichiometry of the reaction. The data in the table are for the reaction of 1.00 M NaOH with 1.00 M citric acid, $C_6H_8O_7$, in a total solution volume of 60.0 mL.

mL 1.00 M NaOH Used	mL 1.00 M Citric Acid Used	ΔT, °C
20.0	40.0	4.7
30.0	30.0	6.3
40.0	20.0	8.2
50.0	10.0	6.7
55.0	5.0	2.7

(a) Plot ΔT versus mL 1.00 M NaOH, and identify the exact stoichiometric proportions of NaOH and citric acid at the equivalence point of the neutralization reaction.

(b) Why is the temperature change in the neutralization greatest when the reactants are in their exact stoichiometric proportions? That is, why not use an excess of one of the reactants to ensure that the neutralization has gone to completion to achieve the maximum temperature increase?

(c) Rewrite the formula of citric acid to reflect more precisely its acidic properties. Then write a balanced net ionic equation for the neutralization reaction.

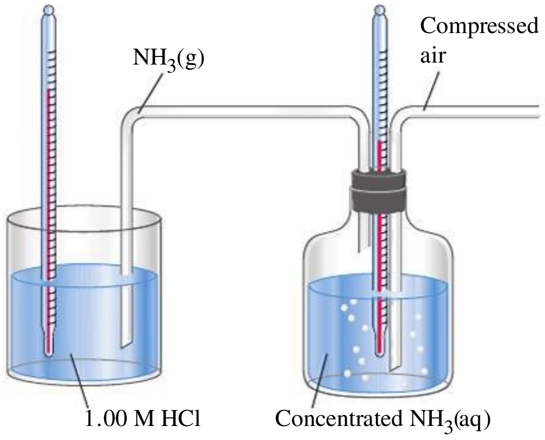
123. In a student experiment to confirm Hess's law, the reaction

$$NH_3(\text{concd aq}) + HCl(aq) \longrightarrow NH_4Cl(aq)$$

was carried out in two different ways. First, 8.00 mL of concentrated $NH_3(aq)$ was added to 100.0 mL of 1.00 M HCl in a calorimeter. [The $NH_3(aq)$ was slightly in excess.] The reactants were initially at 23.8 °C, and the final temperature after neutralization was 35.8 °C. In the second experiment, air was bubbled through 100.0 mL of concentrated $NH_3(aq)$, sweeping out $NH_3(g)$ (see sketch). The $NH_3(g)$ was neutralized in 100.0 mL of 1.00 M HCl. The temperature of the concentrated $NH_3(aq)$ fell from 19.3 to 13.2 °C. At the same time, the temperature of the 1.00 M HCl rose from 23.8 to 42.9 °C as it was neutralized by $NH_3(g)$. Assume that all solutions have densities of 1.00 g/mL and specific heats of $4.18\,\mathrm{J\,g^{-1}\,°C^{-1}}$.

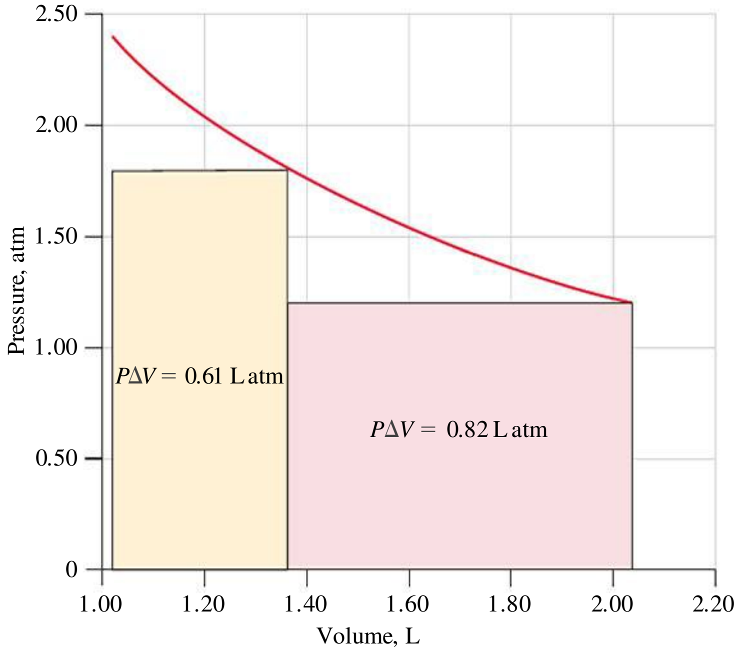
(a) Write the two equations and ΔH values for the processes occurring in the second experiment. Show that the sum of these two equations is the same as the equation for the reaction in the first experiment.

(b) Show that, within the limits of experimental error, ΔH for the overall reaction is the same in the two experiments, thereby confirming Hess's law.



124. When an ideal gas is heated, the change in internal energy is limited to increasing the average translational kinetic energy of the gas molecules. Thus, there is a simple relationship between ΔU of the gas and the change in temperature that occurs. Derive this relationship with the help of ideas about the kinetic-molecular theory of gases developed in Chapter 6. After doing so, obtain numerical values (in $\text{J mol}^{-1}\,\text{K}^{-1}$) for the following molar heat capacities.
(a) The heat capacity, C_V, for one mole of gas under constant-volume conditions
(b) The heat capacity, C_P, for one mole of gas under constant-pressure conditions

125. Refer to Example 7-5 dealing with the work done by 0.100 mol He at 298 K in expanding in a single step from 2.40 to 1.20 atm. Review also the two-step expansion $(2.40\text{ atm} \longrightarrow 1.80\text{ atm} \longrightarrow 1.20\text{ atm})$ described on page 257 (see Figure 7-11).
(a) Determine the total work that would be done if the He expanded in a series of steps, at 0.10 atm intervals, from 2.40 to 1.20 atm.
(b) Represent this total work on the graph below, in which the quantity of work done in the two-step expansion is represented by the sum of the colored rectangles.
(c) Show that the maximum amount of work would occur if the expansion occurred in an infinite number of steps. To do this, express each infinitesimal quantity of work as $dw = P\,dV$ and use the methods of integral calculus (integration) to sum these quantities. Assume ideal behavior for the gas.
(d) Imagine reversing the process, that is, compressing the He from 1.20 to 2.40 atm. What are the maximum and minimum amounts of work required to produce this compression? Explain.
(e) In the isothermal compression described in part (d), what is the change in internal energy assuming ideal gas behavior? What is the value of q?
(f) Using the formula for the work derived in part (c), obtain an expression for q/T. Is this new function a state function? Explain.



126. Look up the specific heat of several elements, and plot the products of the specific heats and atomic masses as a function of the atomic masses. Based on the plot, develop a hypothesis to explain the data. How could you test your hypothesis?

Self-Assessment Exercises

127. In your own words, define or explain the following terms or symbols: **(a)** ΔH; **(b)** $P\Delta V$; **(c)** ΔH_f°; **(d)** standard state; **(e)** fossil fuel.

128. Briefly describe each of the following ideas or methods: **(a)** law of conservation of energy; **(b)** bomb calorimetry; **(c)** function of state; **(d)** enthalpy diagram; **(e)** Hess's law.

129. Explain the important distinctions between each pair of terms: **(a)** system and surroundings; **(b)** heat and work; **(c)** specific heat and heat capacity; **(d)** endothermic and exothermic; **(e)** constant-volume process and constant-pressure process.

130. The temperature increase of 225 mL of water at 25 °C contained in a Styrofoam cup is noted when a 125 g sample of a metal at 75 °C is added. With reference to Table 7.1, the greatest temperature increase will be noted if the metal is **(a)** lead; **(b)** aluminum; **(c)** iron; **(d)** copper.

131. A plausible final temperature when 75.0 mL of water at 80.0 °C is added to 100.0 mL of water at 20 °C is **(a)** 28 °C; **(b)** 40 °C; **(c)** 46 °C; **(d)** 50 °C.

132. $\Delta U = 100$ J for a system that gives off 100 J of heat and **(a)** does no work; **(b)** does 200 J of work; **(c)** has 100 J of work done on it; **(d)** has 200 J of work done on it.

133. The heat of solution of NaOH(s) in water is −41.6 kJ/mol NaOH. When NaOH(s) is dissolved in water the solution temperature **(a)** increases; **(b)** decreases; **(c)** remains constant; **(d)** either increases or decreases, depending on how much NaOH is dissolved.

134. The standard molar enthalpy of formation of $CO_2(g)$ is equal to **(a)** 0; **(b)** the standard molar heat of combustion of graphite; **(c)** the sum of the standard molar enthalpies of formation of CO(g) and $O_2(g)$; **(d)** the standard molar heat of combustion of CO(g).

135. Which two of the following statements are false? **(a)** $q_V = q_P$ for the reaction $N_2(g) + O_2(g) \longrightarrow 2\,NO(g)$; **(b)** $\Delta H > 0$ for an endothermic reaction; **(c)** By convention, the most stable form of an element must always be chosen as the reference form and assigned the value $\Delta H_f^\circ = 0$; **(d)** ΔU and ΔH for a reaction can never have the same value; **(e)** $\Delta H < 0$ for the neutralization of a strong acid by a strong base.

136. A 1.22 kg piece of iron at 126.5 °C is dropped into 981 g water at 22.1 °C. The temperature rises to 34.4 °C. What will be the final temperature if this same piece of iron at 99.8 °C is dropped into 325 mL of glycerol, $HOCH_2CH(OH)CH_2OH(l)$ at 26.2 °C? For glycerol, $d = 1.26$ g/mL; $C_p = 219\ \text{J K}^{-1}\ \text{mol}^{-1}$.

137. Write the balanced chemical equations for reactions that have the following as their standard enthalpy changes.
(a) $\Delta H_f^\circ = +82.05$ kJ/mol $N_2O(g)$
(b) $\Delta H_f^\circ = -394.1$ kJ/mol $SO_2Cl_2(l)$
(c) $\Delta H_{comb}^\circ = -1527$ kJ/mol $CH_3CH_2COOH(l)$

138. The standard molar heats of combustion of C(graphite) and CO(g) are −393.5 and −283 kJ/mol, respectively. Use those data and that for the following reaction

$$CO(g) + Cl_2(g) \longrightarrow COCl_2(g) \qquad \Delta H^\circ = -108\ \text{kJ}$$

to calculate the standard molar enthalpy of formation of $COCl_2(g)$.

139. Can a chemical compound have a standard enthalpy of formation of zero? If so, how likely is this to occur? Explain.

140. Is it possible for a chemical reaction to have $\Delta U < 0$ and $\Delta H > 0$? Explain.

141. Use principles from this chapter to explain the observation that professional chefs prefer to cook with a gas stove rather than an electric stove.

142. Hot water and a piece of cold metal come into contact in an isolated container. When the final temperature of the metal and water are identical, is the total energy change in this process **(a)** zero; **(b)** negative; **(c)** positive; **(d)** not enough information.

143. A clay pot containing water at 25 °C is placed in the shade on a day in which the temperature is 30 °C. The outside of the clay pot is kept moist. Will the temperature of the water inside the clay pot **(a)** increase; **(b)** decrease; **(c)** remain the same?

144. Construct a concept map encompassing the ideas behind the first law of thermodynamics.

145. Construct a concept map to show the use of enthalpy for chemical reactions.

146. Construct a concept map to show the interrelationships between path-dependent and path-independent quantities in thermodynamics.

This image of two neurons (gray objects) is produced by an electron microscope that relies on the wave properties of electrons discussed in this chapter.

At the end of the nineteenth century, some observers of the scientific scene believed that it was nearly time to close the books on the field of physics. They thought that with the accumulated knowledge of the previous two or three centuries, the main work left to be done was to apply this body of physics—classical physics—to such fields as chemistry and biology.

Only a few fundamental problems remained, including an explanation of certain details of light emission and a phenomenon known as the photoelectric effect. But the solution to these problems, rather than marking an end in the study of physics, spelled the beginning of a new golden age of physics. These problems were solved through a bold new proposal—the quantum theory—a scientific breakthrough of epic proportions. In this chapter, we will see that to explain phenomena at the atomic and molecular level, classical physics is inadequate—only the quantum theory will do.

The aspect of quantum mechanics emphasized in this chapter is how electrons are described through features known as quantum numbers and electron orbitals. The model of atomic structure developed here will explain many of the topics discussed in the next several chapters: periodic trends in the physical and chemical properties of the elements, chemical bonding, and intermolecular forces.

8-1 Electromagnetic Radiation

Our understanding of the electronic structures of atoms will be gained by studying the interactions of electromagnetic radiation and matter. The chapter begins with background information about electromagnetic radiation, and then turns to connections between electromagnetic radiation and atomic structure. The best approach to learning material in this chapter is to concentrate on the basic ideas relating to atomic structure, many of which are illustrated through the in-text examples. At the same time, pursue further details of interest in some of the Are You Wondering features and portions of Sections 8-6, 8-8, and 8-10.

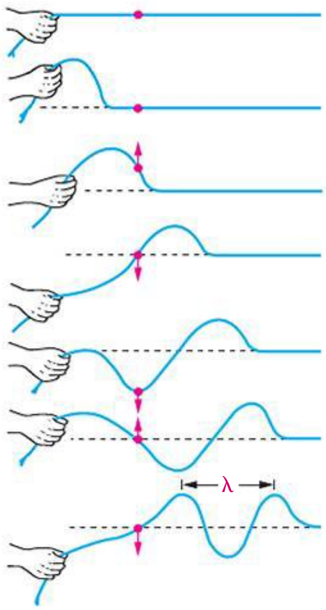
Electromagnetic radiation is a form of energy transmission in which electric and magnetic fields are propagated as waves through empty space (a vacuum) or through a medium, such as glass. A **wave** is a disturbance that transmits energy through space or a material medium. Anyone who has sat in a small boat on a large body of water has experienced wave motion. The wave moves across the surface of the water, and the disturbance alternately lifts the boat and allows it to drop. Although water waves may be more familiar, let us use a simpler example to illustrate some important ideas and terminology about waves—a traveling wave in a rope.

◀ Water waves, sound waves, and seismic waves (which produce earthquakes) are unlike electromagnetic radiation. They require a material medium for their transmission.

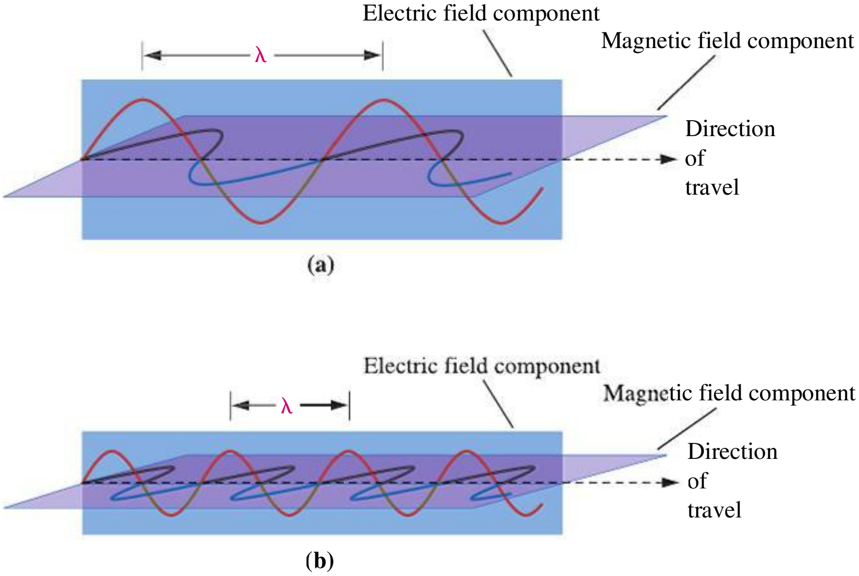
Imagine tying one end of a long rope to a post and holding the other end in your hand (Fig. 8-1). Imagine also that you have marked one small segment of the rope with red ink. As you move your hand up and down, you set up a wave motion in the rope. The wave travels along the rope toward the distant post, but the colored segment simply moves up and down. In relation to the center line (the broken line in Figure 8-1), the wave consists of *crests*, or high points, where the rope is at its greatest height above the center line, and *troughs*, or low points, where the rope is at its greatest depth below the center line. The maximum height of the wave above the center line or the maximum depth below is called the **amplitude**. The distance between the tops of two successive crests (or the bottoms of two troughs) is called the **wavelength**, designated by the Greek letter lambda, λ.

Wavelength is one important characteristic of a wave. Another feature, **frequency**, designated by the Greek letter nu, ν, is the number of crests or troughs that pass through a given point per unit of time. Frequency has the unit, time^{-1}, usually s^{-1} (per second), meaning the number of events or cycles per second. The product of the length of a wave (λ) and the frequency (ν) shows how far the wave front travels in a unit of time. This is the speed of the wave. Thus, if the wavelength in Figure 8-1 were 0.5 m and the frequency, $3\,s^{-1}$ (meaning three complete up-and-down hand motions per second), the speed of the wave would be $0.5\,m \times 3\,s^{-1} = 1.5\,m/s$.

We cannot actually see an electromagnetic wave as we do the traveling wave in a rope, but we can try to represent it as in Figure 8-2. As the figure shows, the magnetic field component lies in a plane perpendicular to the electric field component. An electric field is the region around an electrically charged particle. The presence of an electric field can be detected by measuring the force on an electrically charged object when it is brought into the field. A magnetic field is found in the region surrounding a magnet. According to a theory proposed by James Clerk Maxwell (1831–1879) in 1865, electromagnetic radiation—a propagation of electric and magnetic fields—is produced by an accelerating electrically charged particle (a charged particle whose velocity changes). Radio waves, for example, are a form of electromagnetic radiation produced by causing oscillations (fluctuations) of the electric current in a specially designed electrical circuit. With visible light, another



▲ FIGURE 8-1
The simplest wave motion—traveling wave in a rope
As a result of the up-and-down hand motion (top to bottom), waves pass along the long rope from left to right. This one-dimensional moving wave is called a traveling wave. The wavelength of the wave, λ—the distance between two successive crests—is identified.



▲ FIGURE 8-2
Electromagnetic waves
This sketch of two different electromagnetic waves shows the propagation of mutually perpendicular oscillating electric and magnetic fields. For a given wave, the wavelengths, frequencies, and amplitudes of the electric and magnetic field components are identical. If these views are of the same instant of time, we would say that **(a)** has the longer wavelength and lower frequency, and **(b)** has the shorter wavelength and higher frequency.

form of electromagnetic radiation, the accelerating charged particles are the electrons in atoms or molecules.

Frequency, Wavelength, and Speed of Electromagnetic Radiation

▶ Electromagnetic waves are *transverse* waves—the electric and magnetic fields are *perpendicular* to the perceived direction of motion. So, to a first approximation, are water waves. Sound waves, by contrast, are *longitudinal*. This effect is the result of small pulses of pressure that move in the *same* direction as the sound travels.

The SI unit for frequency, s^{-1}, is the **hertz** (**Hz**), and the basic SI wavelength unit is the meter (m). Because many types of electromagnetic radiation have very short wavelengths, however, smaller units, including those listed below, are also used. The angstrom, named for the Swedish physicist Anders Ångström (1814–1874), is not an SI unit.

1 centimeter (cm) $= 1 \times 10^{-2}$ m
1 millimeter (mm) $= 1 \times 10^{-3}$ m
1 micrometer (μm) $= 1 \times 10^{-6}$ m
1 nanometer (nm) $= 1 \times 10^{-9}$ m $= 1 \times 10^{-7}$ cm $= 10$ Å
1 angstrom (Å) $= 1 \times 10^{-10}$ m $= 1 \times 10^{-8}$ cm $= 100$ pm
1 picometer (pm) $= 1 \times 10^{-12}$ m $= 1 \times 10^{-10}$ cm $= 10^{-2}$ Å

▶ The speed of light is commonly rounded off to $3.00 \times 10^{8}\ \text{m s}^{-1}$.

A distinctive feature of electromagnetic radiation is its *constant* speed of $2.99792458 \times 10^{8}\ \text{m s}^{-1}$ in a vacuum, often referred to as the **speed of light**. The speed of light is represented by the symbol c, and the relationship between this speed and the frequency and wavelength of electromagnetic radiation is

$$c = \nu \times \lambda \tag{8.1}$$

Figure 8-3 indicates the wide range of possible wavelengths and frequencies for some common types of electromagnetic radiation and illustrates this important fact: The wavelength of electromagnetic radiation is shorter for high frequencies and longer for low frequencies. Example 8-1 illustrates the use of equation (8.1).

The electromagnetic spectrum
The visible region, which extends from violet at the shortest wavelength to red at the longest wavelength, is only a small portion of the entire spectrum. The approximate wavelength and frequency ranges of some other forms of electromagnetic radiation are also indicated.

EXAMPLE 8-1 Relating Frequency and Wavelength of Electromagnetic Radiation

Most of the light from a sodium vapor lamp has a wavelength of 589 nm. What is the frequency of this radiation?

Analyze

To use equation (8.1), we first convert the wavelength of the light from nanometers to meters, since the speed of light is in m s^{-1}. Then, we rearrange it to the form $\nu = c/\lambda$ and solve for ν.

Solve

Change the units of λ from nanometers to meters.

$$\lambda = 589\text{ nm} \times \frac{1 \times 10^{-9}\text{ m}}{1\text{ nm}} = 5.89 \times 10^{-7}\text{ m}$$
$$c = 2.998 \times 10^{8}\text{ m s}^{-1}$$
$$\nu = ?$$

Rearrange equation (8.1) to the form $\nu = c/\lambda$, and solve for ν.

$$\nu = \frac{c}{\lambda} = \frac{2.998 \times 10^{8}\text{ m s}^{-1}}{5.89 \times 10^{-7}\text{ m}} = 5.09 \times 10^{14}\text{ s}^{-1} = 5.09 \times 10^{14}\text{ Hz}$$

Assess

The essential element here is to recognize the need to change the units of λ. This change is often needed when converting wavelength to frequency and vice versa.

PRACTICE EXAMPLE A: The light from red LEDs (light-emitting diodes) is commonly seen in many electronic devices. A typical LED produces 690 nm light. What is the frequency of this light?

PRACTICE EXAMPLE B: An FM radio station broadcasts on a frequency of 91.5 megahertz (MHz). What is the wavelength of these radio waves in meters?

(b) CD reflection.

An Important Characteristic of Electromagnetic Waves

The properties of electromagnetic radiation that we will use most extensively are those just introduced—amplitude, wavelength, frequency, and speed. Another essential characteristic of electromagnetic radiation, which will underpin our discussion of atomic structure later in the chapter, is described next.

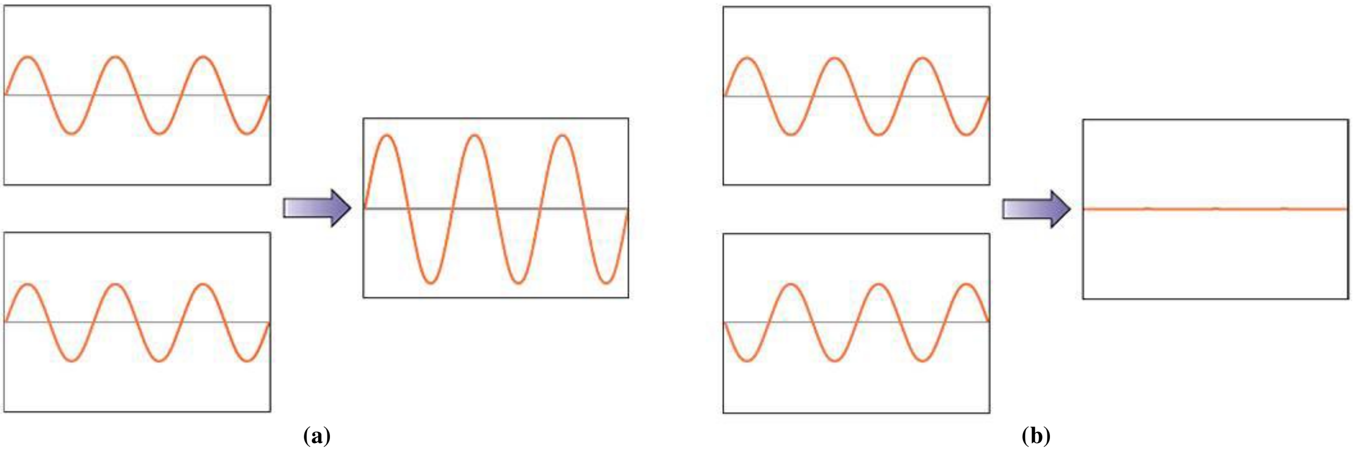
If two pebbles are dropped close together into a pond, ripples (waves) emerge from the points of impact of the two stones. The two sets of waves intersect, and there are places where the waves disappear and places where the waves persist, creating a crisscross pattern (Fig. 8-4a). Where the waves are "in step" upon meeting, their crests coincide, as do their troughs. The waves combine to produce the highest crests and deepest troughs in the water. The waves are said to be *in phase*, and the addition of the waves is called *constructive interference* (Fig. 8-5a). Where the waves meet in such a way that the peak of one wave occurs at the trough of another, the waves cancel and the water is flat (Fig. 8-5b). These out-of-step waves are said to be *out of phase*, and the cancellation of the waves is called *destructive interference*.

An everyday illustration of interference involving electromagnetic waves is seen in the rainbow of colors that shine from the surface of a compact disc (Fig. 8-4b). White light, such as sunlight, contains all the colors of the rainbow. The colors differ in wavelength (and frequency), and when these different wavelength components are reflected off the tightly spaced grooves of the CD,

▶ The *wave nature of light* is demonstrated by its ability to be dispersed by diffraction and refraction.

KEEP IN MIND

that destructive interference occurs when waves are out of phase by one-half wavelength. If waves are out of phase by more or less than this, but also not completely in phase, then only partial destructive interference occurs.



(a) (b)

▲ FIGURE 8-5
Interference in two overlapping light waves
(a) In constructive interference, the troughs and crests are in step (in phase), leading to addition of the two waves. **(b)** In destructive interference, the troughs and crests are out of step (out of phase), leading to cancellation of the two waves.

8-1 ARE YOU WONDERING...

What happens to the energy of an electromagnetic wave when interference takes place?

As noted in Figure 8-2, an electromagnetic wave is made up of oscillating electric (E) and magnetic (B) fields. The magnitudes of E and B continuously oscillate between positive and negative. These oscillating fields create an oscillating electromagnetic force. A charged particle will interact with the electromagnetic force and will oscillate back and forth with a constantly changing velocity. The changing velocity gives the particle a changing kinetic energy that is proportional to the square of the velocity (that is, $e_k = \frac{1}{2}mu^2$). Consequently the energy of a wave depends not on the values of E and B alone, but on the sum of their squares, that is, on $E^2 + B^2$. The energy is also related to the *intensity* (I) of a wave, a quantity which, in turn, is related to the *square* of the wave amplitude.

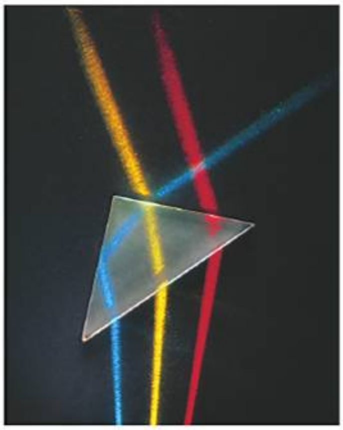
Suppose we let the amplitude of the waves $= 1$. Then for each wave, whether a pair of waves is in phase or out of phase, the energy is proportional to $1^2 + 1^2 = 2$. The average energy of the pair of waves is also proportional to two [that is, $(2 + 2)/2$]. In constructive interference, the amplitudes become two, so that the energy is proportional to four. In destructive interference, the amplitude is zero and the energy is zero. Note, however, that the *average* between the two situations is still two [that is, $(4 + 0)/2$] so that energy is conserved, as it must be.

they travel slightly different distances. This creates phase differences that depend on the angle at which we hold the CD to the light source. The light waves in the beam interfere with each other, and, for a given angle between the incoming and reflected light, all colors cancel except one. Light waves of that color interfere constructively and reinforce one another. Thus, as we change the angle of the CD to the light source, we see different colors. The dispersion of different wavelength components of a light beam through the interference produced by reflection from a grooved surface is called **diffraction**.

Diffraction is a phenomenon that can be explained only as a property of waves. Both the physical picture and mathematics of interference and diffraction are the same for water waves and electromagnetic waves.

The Visible Spectrum

The speed of light is lower in any medium than it is in a vacuum. Also, the speed is different in different media. As a consequence, light is refracted, or bent, when it passes from one medium to another (Fig. 8-6). Moreover, although electromagnetic waves all have the same speed in a vacuum, waves of different wavelengths have slightly different speeds in air and other media. Thus, when a beam of white light is passed through a transparent medium, the wavelength components are refracted differently. The light is dispersed into a band of colors, a *spectrum*. In Figure 8-7(a), a beam of white light (for example, sunlight) is dispersed by a glass prism into a continuous band of colors corresponding to all the wavelength components from red to violet. This is the visible spectrum shown in Figure 8-3 and also seen in a rainbow, where the medium that disperses the sunlight is droplets of water (Fig. 8-7b).

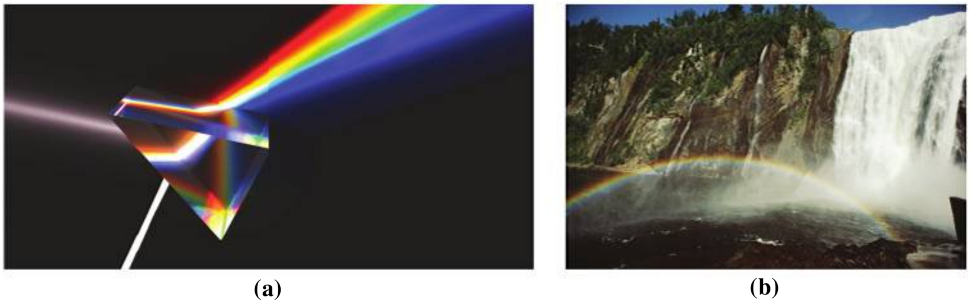


▲ FIGURE 8-6
Refraction of light
Light is refracted (bent) as it passes from air into the glass prism, and again as it emerges from the prism into air. This photograph shows that red light is refracted the least and blue light the most. The blue light strikes the prism at such an angle that the beam undergoes an internal reflection before it emerges from the prism.

8-1 CONCEPT ASSESSMENT

Red laser light is passed through a device called a frequency doubler. What is the approximate color of the light that exits the frequency doubler? How are the wavelengths of the original light and the frequency-doubled light related?

▶ The *importance of light* to chemistry is that light is a form of energy and that by studying light–matter interactions we can detect energy changes in atoms and molecules. Another means of monitoring the energy of a system is through observations of heat transfer. Light can be more closely controlled and thus gives us more detailed information than can be obtained with heat measurements.

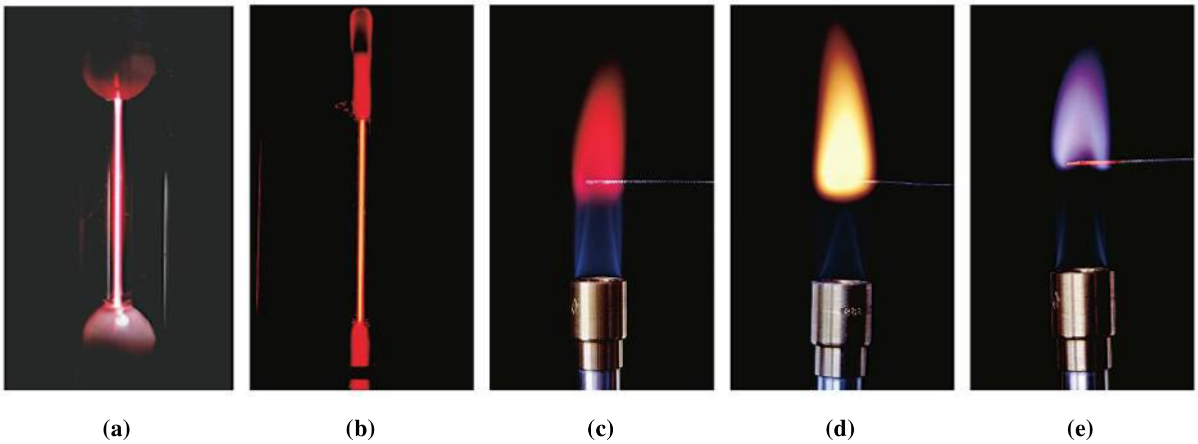


▲ FIGURE 8-7
The spectrum of "white" light
(a) Dispersion of light through a prism. Red light is refracted the least and violet light the most when "white" light is passed through a glass prism. The other colors of the visible spectrum are found between red and violet. **(b)** Rainbow near a waterfall. Here, water droplets are the dispersion medium.

8-2 Atomic Spectra

The visible spectrum in Figure 8-7 is said to be a *continuous spectrum* because the light being diffracted consists of many wavelength components. If the source of a spectrum produces light having only a relatively small number of wavelength components, then a *discontinuous spectrum* is observed. For example, if the light source is an electric discharge passing through a gas, only certain colors are seen in the spectrum (Fig. 8-8a and b). Or, if the light source is a gas flame into which an ionic compound has been introduced, the flame may acquire a distinctive color indicative of the metal ion present (Fig. 8-8c–e). In each of these cases, the emitted light produces a spectrum consisting of only a limited number of discrete wavelength components, observed as colored lines with dark spaces between them. These discontinuous spectra are called **atomic**, or **line**, **spectra**.

The production of the line spectrum of helium is illustrated in Figure 8-9. The light source is a lamp containing helium gas at a low pressure. When an electric discharge is passed through the lamp, helium atoms absorb energy, which they then emit as light. The light is passed through a narrow slit and then dispersed by a prism. The colored components of the light are detected and recorded on photographic film. Each wavelength component appears as



▲ FIGURE 8-8
Sources for light emission

◀ FIGURE 8-9
The atomic, or line, spectrum of helium
The apparatus pictured here, in which the spectral lines are photographed, is called a *spectrograph*. If the observations are made by visual sighting alone, the device is called a *spectroscope*. If the positions and brightness of the lines are measured and recorded by other than visual or photographic means, the term generally used is *spectrometer*.

an image of the slit—a thin line. In all, there are five lines in the spectrum of helium that can be seen with the unaided eye.

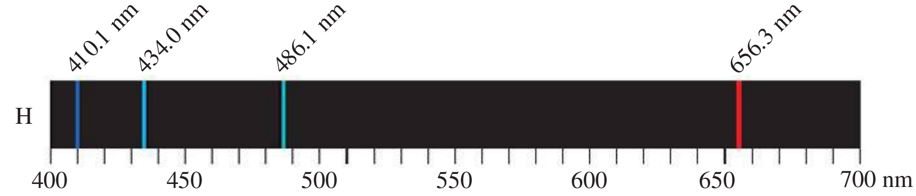
Each element has its own distinctive line spectrum—a kind of atomic fingerprint. Robert Bunsen (1811–1899) and Gustav Kirchhoff (1824–1887) developed the first spectroscope and used it to identify elements. In 1860, they discovered a new element and named it cesium (Latin, *caesius*, sky blue) because of the distinctive blue lines in its spectrum. They discovered rubidium in 1861 in a similar way (Latin, *rubidius*, deepest red). Still another element characterized by its unique spectrum is helium (Greek, *helios*, the sun). Its spectrum was observed during the solar eclipse of 1868, but helium was not isolated on Earth for another 27 years.

◀ Bunsen designed a special gas burner for his spectroscopic studies. This burner, the common laboratory Bunsen burner, produces very little background radiation to interfere with spectral observations.

Among the most extensively studied atomic spectra has been the hydrogen spectrum. Light from a hydrogen lamp appears to the eye as a reddish purple color (Fig. 8-8a). The principal wavelength component of this light is red light of wavelength 656.3 nm. Three other lines appear in the visible spectrum of atomic hydrogen, however: a greenish blue line at 486.1 nm, a violet line at 434.0 nm, and another violet line at 410.1 nm. The visible atomic spectrum of hydrogen is shown in Figure 8-10. In 1885, Johann Balmer, apparently through trial and error, deduced a formula for the wavelengths of these spectral lines. Balmer's equation, rearranged to a form based on frequency, is

$$\nu = 3.2881 \times 10^{15}\,\text{s}^{-1}\left(\frac{1}{2^2} - \frac{1}{n^2}\right) \qquad \textbf{(8.2)}$$

In this equation, ν is the frequency of the spectral line, and n must be an *integer* (whole number) *greater than two*. If $n = 3$ is substituted into the equation, the



▲ FIGURE 8-10
The Balmer series for hydrogen atoms—a line spectrum
The four lines shown are the only ones visible to the unaided eye. Additional, closely spaced lines lie in the ultraviolet (UV) region.

frequency of the red line is obtained. If $n = 4$ is used in equation 8.2, the frequency of the greenish blue line is obtained, and so on.

The fact that atomic spectra consist of only limited numbers of well-defined wavelength lines provides a great opportunity to learn about the structures of atoms. For example, it suggests that only a limited number of energy values are available to excited gaseous atoms. Classical (nineteenth-century) physics, however, was not able to provide an explanation of atomic spectra. The key to this puzzle lay in a great breakthrough of modern science—the quantum theory.

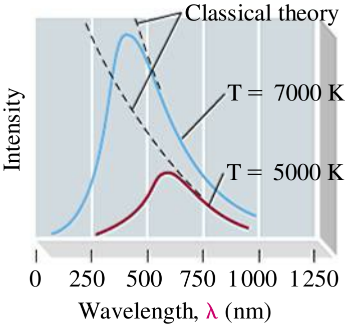
When comet Schumacher-Levy crashed into Jupiter's surface, scientists viewed the event with spectrographs. What did they hope to discover?

8-3 Quantum Theory



▲ FIGURE 8-11
Spectrum of radiation given off by a heated body
A red-hot object has a spectrum that peaks around 675 nm, whereas a white-hot object has a spectrum that has comparable intensities for all wavelengths in the visible region. The sun has a blackbody temperature of about 5750 K. Objects emit radiation at *all* temperatures, not just at high temperatures. For example, night-vision goggles makes infrared radiation emitted by objects visible in the dark.

We are aware that hot objects emit light of different colors, from the dull red of an electric-stove heating element to the bright white of a light bulb filament. Light emitted by a hot radiating object can be dispersed by a prism to produce a continuous color spectrum. As seen in Figure 8-11, the light intensity varies smoothly with wavelength, peaking at a wavelength fixed by the source temperature. As with atomic spectra, classical physics could not provide a complete explanation of light emission by heated solids, a process known as *blackbody radiation*. Classical theory predicts that the intensity of the radiation emitted would increase indefinitely, as indicated by the dashed lines in Figure 8-11. In 1900, to explain the fact that the intensity does not increase indefinitely, Max Planck (1858–1947) made a revolutionary proposal: *Energy, like matter, is discontinuous.* Here, then, is the essential difference between the classical physics of Planck's time and the new quantum theory that he proposed: Classical physics places no limitations on the amount of energy a system may possess, whereas quantum theory limits this energy to a discrete set of specific values. The *difference* between any two allowed energies of a system also has a specific value, called a **quantum** of energy. This means that when the energy increases from one allowed value to another, it increases by a tiny jump, or quantum. Here is a way of thinking about a quantum of energy: It bears a similar relationship to the total energy of a system as a single atom does to an entire sample of matter.

The model Planck used for the emission of electromagnetic radiation was that of a group of atoms on the surface of the heated object oscillating together with the same frequency. Planck's assumption was that the group of atoms, the oscillator, must have an energy corresponding to the equation

$$\epsilon = nh\nu$$

where ϵ is the energy, n is a positive integer, ν is the oscillator frequency, and h is a constant that had to be determined by experiment. By using his theory and experimental data for the distribution of frequencies with temperature, Planck established the following value for the constant h. We now call it **Planck's constant**, and it has the value

$$h = 6.62607 \times 10^{-34}\,\mathrm{J\,s}$$

▶ Planck's equation can be used to develop relationships among frequency, wavelength, and energy. By using this information, the relative energies of radiation on the electromagnetic spectrum can be compared.

Planck's postulate can be rephrased in this more general way: The energy of a quantum of electromagnetic radiation is proportional to the frequency of the radiation—the higher the frequency, the greater the energy. This is summarized by what we now call Planck's equation.

$$E = h\nu \tag{8.3}$$

8-2 ARE YOU WONDERING...

How Planck's ideas account for the fact that the intensity of blackbody radiation drops off at higher frequencies?

Planck was aware of the work of Ludwig Boltzmann, who, with James Maxwell, had derived an equation to account for the distribution of molecular speeds. Boltzmann had shown that the relative chance of finding a molecule with a particular speed was related to its energy by the following expression.

$$\text{relative chance} \propto e^{\left(-\frac{\text{kinetic energy}}{k_B T}\right)}$$

where k_B is the Boltzmann constant, and T is the Kelvin temperature. You will also notice that the curve of intensity versus wavelength in Figure 8-11 bears a strong resemblance to the distribution of molecular speeds in Figure 6-15. Planck assumed that the energies of the substance oscillating to emit blackbody radiation were distributed according to the Boltzmann distribution law. That is, the relative chance of an oscillator having the energy $nh\nu$ is proportional to $e^{-nh\nu/k_B T}$, where n is an integer, 1, 2, 3, and so on. So this expression shows that the chance of an oscillator having a high frequency is lower than for oscillators having lower frequencies because as n increases, $e^{-nh\nu/k_B T}$, decreases. The assumption that the energy of the oscillators in the light-emitting source cannot have continuous values leads to excellent agreement between theory and experiment.

▲ **Max Planck (1858–1947)**

At the time Planck made his quantum hypothesis, scientists had had no previous experience with macroscopic physical systems that required the existence of separate energy levels and that energy may only be emitted or absorbed in specific quanta. Their experience was that there were no theoretical limits on the energy of a system and that the transfer of energy was continuous. Thus it is not surprising that scientists, including Planck himself, were initially skeptical of the quantum hypothesis. It had been designed to explain radiation from heated bodies and certainly could not be accepted as a general principle until it had been tested on other applications.

Only after the quantum hypothesis was successfully applied to phenomena other than blackbody radiation did it acquire status as a great new scientific theory. The first of these successes came in 1905 with Albert Einstein's quantum explanation of the photoelectric effect.

The Photoelectric Effect

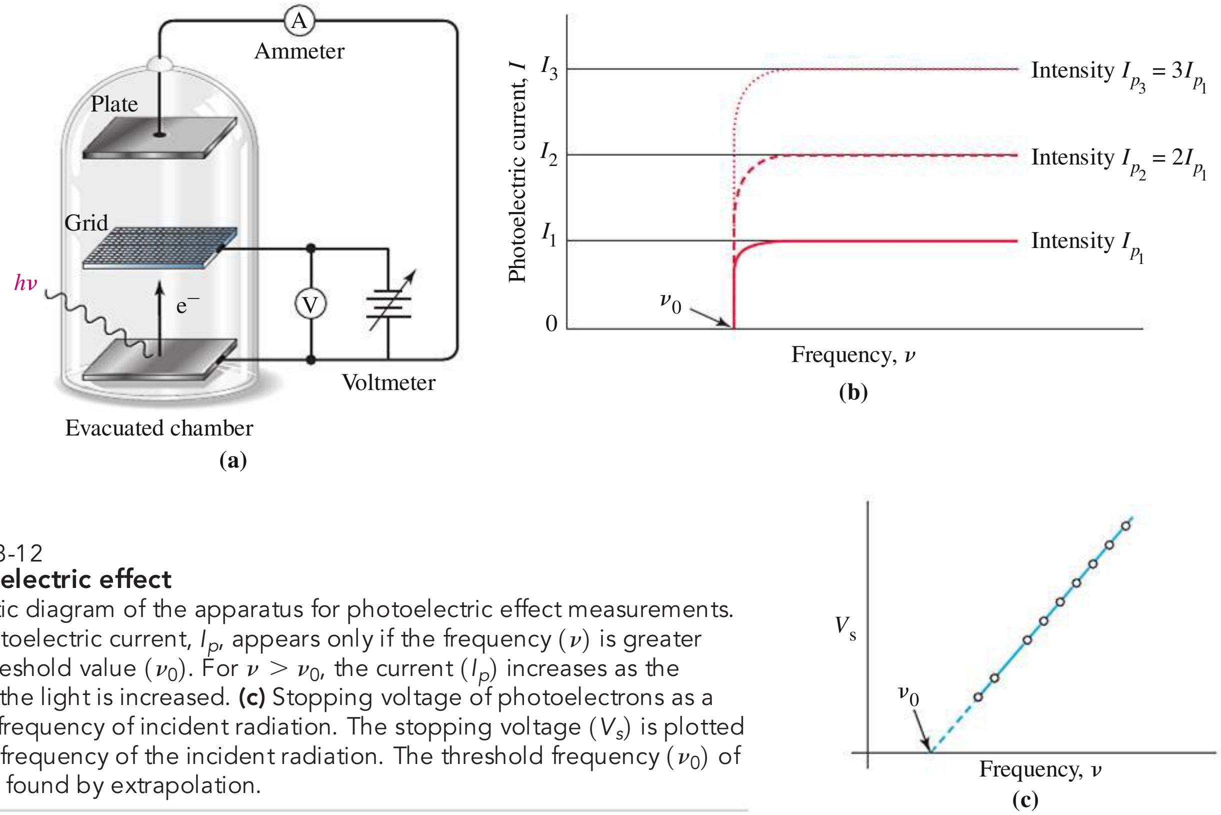
In 1888, Heinrich Hertz discovered that when light strikes the surface of certain metals, electrons are ejected. This phenomenon is called the **photoelectric effect** and its salient feature is that electron emission only occurs when the frequency of the incident light exceeds a particular threshold value (ν_0). When this condition is met,

- the number of electrons emitted depends on the intensity of the incident light, but
- the kinetic energies of the emitted electrons depend on the frequency of the light.

These observations, especially the dependency on frequency, could not be explained by classical wave theory. However, Albert Einstein showed that they are exactly what would be expected with a particle interpretation of radiation. In 1905, Einstein proposed that electromagnetic radiation has particle-like qualities and that "particles" of light, subsequently called **photons** by G. N. Lewis, have a characteristic energy given by Planck's equation, $E = h\nu$.

In the particle model, a photon of energy $h\nu$ strikes a bound electron, which absorbs the photon energy. If the photon energy, $h\nu$, is greater than the energy

◀ Light–matter interactions usually involve *one photon per atom or electron*. Thus, to escape from a photoelectric surface, an electron must do so with the energy from a single photon collision. The electron cannot accumulate the energy from several hits by photons.



▲ FIGURE 8-12
The photoelectric effect
(a) Schematic diagram of the apparatus for photoelectric effect measurements. **(b)** The photoelectric current, I_p, appears only if the frequency (ν) is greater than the threshold value (ν_0). For $\nu > \nu_0$, the current (I_p) increases as the intensity of the light is increased. **(c)** Stopping voltage of photoelectrons as a function of frequency of incident radiation. The stopping voltage (V_s) is plotted against the frequency of the incident radiation. The threshold frequency (ν_0) of the metal is found by extrapolation.

▶ With the advent of lasers we have observed the simultaneous absorption of two photons by one electron. Instances of two adjacent molecules cooperatively absorbing one photon are also known. Such occurrences are exceptions to the more normal one photon/one electron phenomena.

binding the electron to the surface (a quantity known as the *work function*), a photoelectron is liberated. Thus, the lowest frequency light producing the photoelectric effect is the threshold frequency, and any energy in excess of the work function appears as kinetic energy in the emitted photoelectrons.

In the discussion that follows, based on the experimental setup shown in Figure 8-12, we will see how the threshold frequency and work function are evaluated. Also, we will see that the photoelectric effect provides an independent evaluation of Planck's constant, *h*.

In Figure 8-12, light (designated $h\nu$) is allowed to shine on a piece of metal in an evacuated chamber. The electrons emitted by the metal (photoelectrons) travel to the upper plate and complete an electric circuit set up to measure the photoelectric current through an ammeter. Figure 8-12(b) illustrates the variation of the photoelectric current, I_p, detected by the ammeter as the frequency (ν) and intensity of the incident light is increased. We see that no matter how intense the light, no current flows if the frequency is below the threshold frequency, ν_0, and no photoelectric current is produced. In addition no matter how weak the light, there is a photoelectric current if $\nu > \nu_0$. The magnitude of the photoelectric current is, as shown in Figure 8-12(b), directly proportional to the intensity of the light, so that the number of photoelectrons increases with the intensity of the incident light. Therefore, we can associate light intensity with the number of photons arriving at a point per unit time.

A second circuit is set up to measure the velocity of the photoelectrons, and hence their kinetic energy. In this circuit, a potential difference (voltage) is maintained between the photoelectric metal and an open-grid electrode placed below the upper plate. For electric current to flow, electrons must pass through the openings in the grid and onto the upper plate. The negative potential on the grid acts to slow down the approaching electrons. As the potential difference between the grid and the emitting metal is increased, a point is reached at which the photoelectrons are stopped at the grid and the current ceases to flow through the ammeter. The potential difference at this point is called the *stopping voltage*, V_s. At the stopping voltage, the kinetic energy of the photoelectrons has been converted to potential energy, expressed through the following equation (in which m, u, and e are the mass, speed, and charge of an electron, respectively).

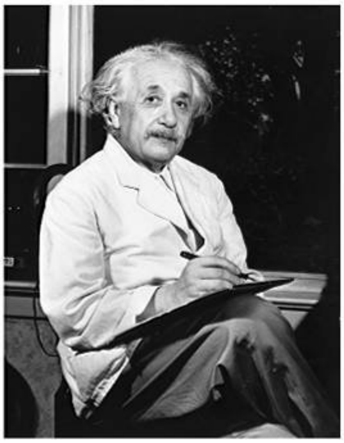
$$\frac{1}{2}mu^2 = eV_s$$

As a result of experiments of the type just described, we find that V_s is proportional to the frequency of the incident light but independent of the light intensity. Also, as shown in Figure 8-12, if the frequency, ν, is below the *threshold frequency*, ν_0, no photoelectric current is produced. At frequencies greater than ν_0, the empirical equation for the stopping voltage is

$$V_s = k(\nu - \nu_0)$$

The constant k is independent of the metal used, but ν_0 varies from one metal to another. Although there is no relation between V_s and the light intensity, the

◀ Albert Einstein received a Nobel Prize for his work on the photoelectric effect. He is better known for his development of the theory of relativity, and $E = mc^2$.



▲ **Albert Einstein (1879–1955)**

8-3 ARE YOU WONDERING...

How the energy of a photon is manifested?

We begin with an important relationship between the mass and velocity of a particle given by Einstein. Let the mass of a particle when the particle and the measuring device are at rest be denoted as m_0. If we remeasure the mass when the particle moves with a velocity u, we find that its mass increases according to the equation

$$m = \frac{m_0}{\sqrt{1 - u^2/c^2}}$$

where m is the particle mass, referred to as the *relativistic mass*, and c is the speed of light. For particles moving at speeds less than 90% of the speed of light, the relativistic mass (m) is essentially the same as the rest mass (m_0).

We have seen that the kinetic energy of a particle is given by

$$E_K = \frac{1}{2}mu^2$$

However, because photons travel at the speed of light they must have zero rest mass (otherwise their relativistic mass m would become infinite). So where is their energy?

Although photons have zero rest mass, they do possess momentum, which is defined as the relativistic mass times the velocity of the particle, because they are in motion. Einstein's theory of special relativity states that a particle's energy and momentum ($p = mu$, recall page 217) are related by the expression

$$E^2 = (pc)^2 + (m_0c^2)^2$$

where m_0 is the rest mass of the particle. For photons traveling at the speed of light c, the rest mass is zero. Hence

$$E = pc = h\nu$$

$$p = \frac{h\nu}{c} = \frac{h}{\lambda}$$

Photons possess momentum, and it is this momentum that is transferred to an electron in a collision. In all collisions between photons and electrons, momentum is conserved. Thus, we see that the wave and the photon models are intimately connected. The energy of a photon is related to the frequency of the wave by Planck's equation, and the momentum of the photon is related to the wavelength of the wave by the equation just derived! When a photon collides with an electron, it transfers momentum to the electron, which accelerates to a new velocity. The energy of the photon decreases, and, as a consequence, its wavelength increases. This phenomenon, called the Compton effect, was discovered in 1923 and confirmed the particulate nature of light.

photoelectric current, I_p, is proportional to the intensity of the light as illustrated in Figure 8-12b.

The work function is a quantity of work and, hence, of energy. One way to express this quantity is as the product of Planck's constant and the threshold frequency: $E = h\nu_0$. Another way is as the product of the charge on the electron, e, and the potential, V_0, that has to be overcome in the metal: $E = eV_0$. Thus, the threshold frequency for the photoelectric effect is given by the expression

$$\nu_0 = \frac{eV_0}{h}$$

Since the work function (eV_0) is a characteristic of the metal used in the experiment, then ν_0 is also a characteristic of the metal, as confirmed by experiment.

When a photon of energy $h\nu$ strikes an electron, the electron overcomes the work function eV_0 and is liberated with kinetic energy $\left(\frac{1}{2}\right)mu^2$. Thus, by the law of conservation of energy, we have

$$\frac{1}{2}mu^2 + eV_0 = h\nu$$

which gives

$$eV_s = \frac{1}{2}mu^2 = h\nu - eV_0$$

which is identical to the empirically determined equation for V_s with $k = h/e$ when $h\nu_0 = eV_0$. Careful experiments showed that the constant h had the same value as determined by Planck for blackbody radiation. The additional fact that the number of photoelectrons increases with the intensity of light indicates that we should associate light intensity with the number of photons arriving at a point per unit time.

8-3 CONCEPT ASSESSMENT

The wavelength of light needed to eject electrons from hydrogen atoms is 91.2 nm. When light of 80.0 nm is shone on a sample of hydrogen atoms, electrons are emitted from the hydrogen gas. If, in a different experiment, the wavelength of the light is changed to 70.0 nm, what is the effect compared to the use of 80.0 nm light? Are more electrons emitted? If not, what happens?

Photons of Light and Chemical Reactions

Chemical reactions that are induced by light are called *photochemical reactions*. Because they are essential to these reactions, we can think of photons as "reactants" and we can designate them in chemical equations by the symbol $h\nu$. The reactions by which ozone molecules, O_3, are produced from oxygen molecules, O_2, are represented below.

$$O_2 + h\nu \longrightarrow O + O$$
$$O_2 + O + M \longrightarrow O_3 + M^*$$

The radiation required in the first reaction is UV radiation with wavelength less than 242.4 nm. O atoms from the first reaction then combine with O_2 to form O_3. In the second reaction, a "third body," M, such as $N_2(g)$, is needed to carry away excess energy to prevent immediate dissociation of O_3 molecules.

▶ The reactions shown here describing the formation ozone from oxygen gas are the reactions that occur in the atmosphere to produce ozone.

Photochemical reactions involving ozone are the subject of Example 8-2. There we see that the product of Planck's constant h and frequency (ν) yields the energy of a single photon of electromagnetic radiation in the unit joule. Invariably, this energy is only a tiny fraction of a joule. Often it is useful to deal with the much larger energy of a mole of photons (6.02214×10^{23} photons).

EXAMPLE 8-2 Using Planck's Equation to Calculate the Energy of Photons of Light

For radiation of wavelength 242.4 nm, the longest wavelength that will bring about the photodissociation of O_2, what is the energy of **(a)** one photon, and **(b)** a mole of photons of this light?

Analyze

To use Planck's equation, we need the frequency of the radiation. We can get this from equation (8.1) after first expressing the wavelength in meters. Planck's equation is written for one photon of light. We emphasize this by including the unit in the value of h. Once we have the energy per photon, we can multiply it by the Avogadro constant to convert to a per-mole basis.

Solve

(a) First, calculate the frequency of the radiation.

$$\nu = \frac{c}{\lambda} = \frac{2.998 \times 10^{8}\ \text{m s}^{-1}}{242.4 \times 10^{-9}\ \text{m}} = 1.237 \times 10^{15}\ \text{s}^{-1}$$

Then, calculate the energy of a single photon.

$$E = h\nu = 6.626 \times 10^{-34} \times \frac{\text{J s}}{\text{photon}} \times 1.237 \times 10^{15}\ \text{s}^{-1}$$
$$= 8.196 \times 10^{-19}\ \text{J/photon}$$

(b) Calculate the energy of a mole of photons.

$$E = 8.196 \times 10^{-19}\ \text{J/photon} \times 6.022 \times 10^{23}\ \text{photons/mol}$$
$$= 4.936 \times 10^{5}\ \text{J/mol}$$

Assess

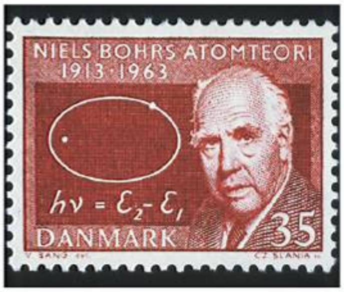
We can see from this example that when the energy of a single photon is expressed in SI units, the energy is rather small and perhaps difficult to interpret. However, the amount of energy carried by a *mole* of photons is something we can easily relate to. As shown above, light with a wavelength of 242.4 nm has an energy content of 493.6 kJ/mol, which is similar in magnitude to the internal energy and enthalpy changes of chemical reactions (see Chapter 7).

PRACTICE EXAMPLE A: The protective action of ozone in the atmosphere comes through ozone's absorption of UV radiation in the 230 to 290 nm wavelength range. What is the energy, in kilojoules per mole, associated with radiation in this wavelength range?

PRACTICE EXAMPLE B: Chlorophyll absorbs light at energies of 3.056×10^{-19} J/photon and 4.414×10^{-19} J/photon To what color and frequency do these absorptions correspond?

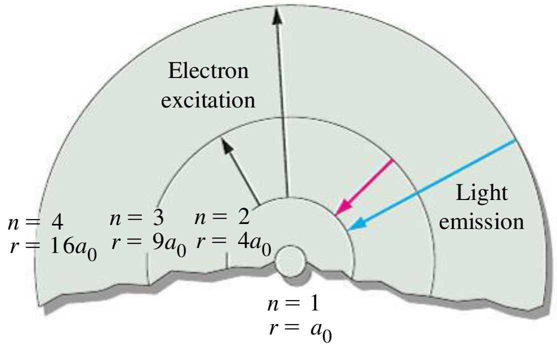
8-4 The Bohr Atom

The Rutherford model of a nuclear atom (Section 2-3) does not indicate how electrons are arranged outside the nucleus of an atom. According to classical physics, stationary, negatively charged electrons would be pulled into the positively charged nucleus. This suggests that the electrons in an atom must be in motion, like the planets orbiting the sun. However, again according to classical physics, orbiting electrons should be constantly accelerating and should radiate energy. By losing energy, the electrons would be drawn ever closer to the nucleus and soon spiral into it. In 1913, Niels Bohr (1885–1962) resolved this problem by using Planck's quantum hypothesis. In an interesting blend of classical and quantum theory, Bohr postulated that for a hydrogen atom:



▲ **Niels Bohr (1885–1962)** In addition to his work on the hydrogen atom, Bohr headed the Institute of Theoretical Physics in Copenhagen, which became a mecca for theoretical physicists in the 1920s and 1930s.

1. The electron moves in circular orbits about the nucleus with the motion described by classical physics.
2. The electron has only a fixed set of allowed orbits, called *stationary states*. The allowed orbits are those in which certain properties of the electron have unique values. Even though classical theory would predict otherwise, *as long as an electron remains in a given orbit, its energy is constant and no energy is emitted*. The particular property of the electron having only certain allowed values, leading to only a discrete set of allowed orbits, is called the *angular momentum*. Its possible



▶ FIGURE 8-13
Bohr model of the hydrogen atom
A portion of the hydrogen atom is pictured. The nucleus is at the center, and the electron is found in one of the discrete orbits, $n = 1, 2$, and so on. Excitation of the atom raises the electron to higher-numbered orbits, as shown with black arrows. Light is emitted when the electron falls to a lower-numbered orbit. Two transitions that produce lines in the Balmer series of the hydrogen spectrum are shown in the approximate colors of the spectral lines.

KEEP IN MIND

that momentum (p) is the product of the mass and the velocity of a particle. If the particle undergoes a circular motion, then the particle possesses angular momentum.

values are $nh/2\pi$, where n must be an integer. Thus the quantum numbers progress: $n = 1$ for the first orbit; $n = 2$ for the second orbit; and so on.

3. An electron can pass only from one allowed orbit to another. In such transitions, fixed discrete quantities of energy (quanta) are involved—either absorbed or emitted.

The atomic model of hydrogen based on these ideas is pictured in Figure 8-13. The allowed states for the electron are numbered, $n = 1, n = 2, n = 3$, and so on. These *integral* numbers, which arise from Bohr's assumption that only certain values are allowed for the angular momentum of the electron, are called **quantum numbers**.

The Bohr theory predicts the radii of the allowed orbits in a hydrogen atom.

$$r_n = n^2 a_0, \text{ where } n = 1, 2, 3, \ldots \quad \text{and} \quad a_0 = 53 \text{ pm } (0.53 \text{ Å}) \tag{8.4}$$

▶ According to the Bohr model, lower energy orbits are closer to the nucleus and electrons associated with low energy orbits must absorb more energy to be removed from the atom.

The theory also allows us to calculate the electron velocities in these orbits and, most important, the energy. When the electron is free of the nucleus, by convention, it is said to be at a *zero* of energy. When a free electron is attracted to the nucleus and confined to the orbit n, the electron energy becomes negative, with its value lowered to

▶ Think of a person on a stairway going up steps (excitation) or down steps (emission). The person must stop on a step—in-between levels are not available.

$$E_n = \frac{-R_H}{n^2} \tag{8.5}$$

R_H is a numerical constant with a value of 2.179×10^{-18} J.

With expression (8.5), we can calculate the energies of the allowed energy states, or *energy levels*, of the hydrogen atom. These levels can be represented schematically as in Figure 8-14. This representation is called an **energy-level diagram**. Example 8-3 shows how Bohr's model can be used to predict whether certain energy levels are possible (allowed) or impossible (not allowed).

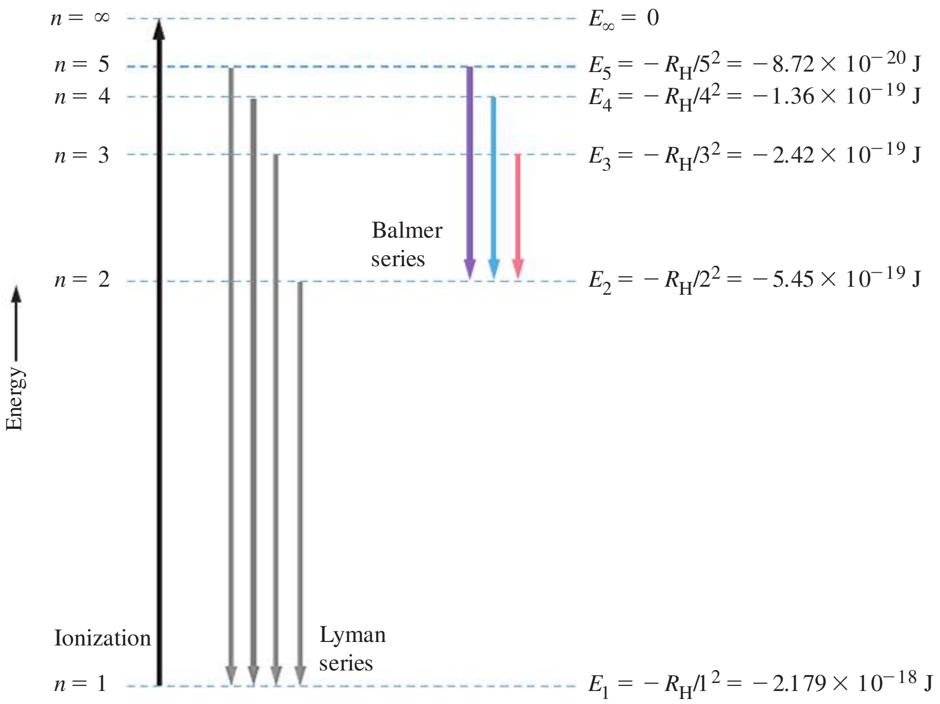
Normally, the electron in a hydrogen atom is found in the orbit closest to the nucleus $(n = 1)$. This is the lowest allowed energy, or the **ground state**. When the electron gains a quantum of energy, it moves to a higher level $(n = 2, 3$, and so on) and the atom is in an **excited state**. When the electron drops from a higher to a lower numbered orbit, a unique quantity of energy is emitted—the difference in energy between the two levels. Equation (8.5) can be used to derive an expression for the difference in energy between two levels, where n_f is the final level and n_i is the initial one.

▶ Notice the resemblance of this equation to the Balmer equation (8.2). In addition to developing a theory of atomic structure to account for Rutherford's atomic model, Bohr sought a theoretical explanation of the Balmer equation.

$$\Delta E = E_f - E_i = \frac{-R_H}{n_f^2} - \frac{-R_H}{n_i^2} = R_H\left(\frac{1}{n_i^2} - \frac{1}{n_f^2}\right) = 2.179 \times 10^{-18}\,\text{J}\left(\frac{1}{n_i^2} - \frac{1}{n_f^2}\right) \tag{8.6}$$

The energy of the photon, E_{photon}, either absorbed or emitted, is equal to the magnitude of this energy difference. Because $E_{\text{photon}} = h\nu$ and $E_{\text{photon}} = |\Delta E|$, we can write

$$|\Delta E| = E_{\text{photon}} = h\nu$$



n = ∞

E2 = −RH/2² = −5.45 × 10⁻¹⁹ J
E1 = −RH/1² = −2.179 × 10⁻¹⁸ J

◀ FIGURE 8-14
Energy-level diagram for the hydrogen atom
If the electron acquires 2.179×10^{-18} J of energy, it moves to the orbit $n = \infty$; ionization of the H atom occurs (black arrow). Energy emitted when the electron falls from higher-numbered orbits to the orbit $n = 1$ is in the form of ultraviolet light, which produces a spectral series called the Lyman series (gray lines). Electron transitions to the orbit $n = 2$ yield lines in the Balmer series (recall Figure 8-10); three of the lines are shown here (in color). Transitions to $n = 3$ yield spectral lines in the infrared.

EXAMPLE 8-3 Understanding the Meaning of Quantization of Energy

Is it likely that there is an energy level for the hydrogen atom, $E_n = -1.00 \times 10^{-20}$ J?

Analyze

Rearrange equation (8.5) for n^2 and solve for n. If the value of n is an integer, then the given energy corresponds to an energy level for the hydrogen atom.

Solve

Let us rearrange equation (8.5), solve for n^2, and then for n.

$$n^2 = \frac{-R_H}{E_n}$$

$$= \frac{-2.179 \times 10^{-18}\ \text{J}}{-1.00 \times 10^{-20}\ \text{J}} = 2.179 \times 10^2 = 217.9$$

$$n = \sqrt{217.9} = 14.76$$

Because the value of n is not an integer, this is not an allowed energy level for the hydrogen atom.

Assess

Equation (8.5) places a severe restriction on the energies allowed for a hydrogen atom.

PRACTICE EXAMPLE A: Is there an energy level for the hydrogen atom, $E_n = -2.69 \times 10^{-20}$ J?

PRACTICE EXAMPLE B: The energy of an electron in a hydrogen atom is -4.45×10^{-20} J. What level does it occupy?

where $|\Delta E|$ represents the *magnitude* of the energy difference between the energy levels involved in the electronic transition.

Example 8-4 uses equation (8.6) as a basis for calculating the lines in the hydrogen emission spectrum. Because the differences between energy levels are limited in number, so too are the energies of the emitted photons. Therefore, only certain wavelengths (or frequencies) are observed for the spectral lines.

EXAMPLE 8-4 Calculating the Wavelength of a Line in the Hydrogen Spectrum

Determine the wavelength of the line in the Balmer series of hydrogen corresponding to the transition from $n = 5$ to $n = 2$.

Analyze

This problem is an application of equation (8.6). After the energy difference is calculated, we can obtain the photon frequency by rearranging $|\Delta E| = E_{\text{photon}} = h\nu$. Equation (8.1) is then used to get the wavelength.

Solve

The specific data for equation (8.6) are $n_{\text{i}} = 5$ and $n_{\text{f}} = 2$.

$$\begin{aligned}\Delta E &= 2.179 \times 10^{-18}\,\text{J}\left(\frac{1}{5^2} - \frac{1}{2^2}\right)\\ &= 2.179 \times 10^{-18} \times (0.04000 - 0.25000)\\ &= -4.576 \times 10^{-19}\,\text{J}\end{aligned}$$

Rearranging $E_{\text{photon}} = \Delta E = h\nu$ gives the frequency

$$\nu = \frac{E_{\text{photon}}}{h} = \frac{4.576 \times 10^{-19}\,\text{J photon}^{-1}}{6.626 \times 10^{-34}\,\text{J s photon}^{-1}} = 6.906 \times 10^{14}\,\text{s}^{-1}$$

Rearranging $c = \lambda\nu$ for the wavelength gives the following result:

$$\lambda = \frac{c}{\nu} = \frac{2.998 \times 10^{8}\,\text{m s}^{-1}}{6.906 \times 10^{14}\,\text{s}^{-1}} = 4.341 \times 10^{-7}\,\text{m} = 434.1\,\text{nm}$$

Assess

Note the good agreement between this result and the data in Figure 8-10. The color of the spectral line is determined by the energy difference, ΔE, while the intensity is determined by the number of hydrogen atoms undergoing this transition. The greater the number of atoms undergoing the same transition, the greater the number of emitted photons, resulting in greater intensity.

PRACTICE EXAMPLE A: Determine the wavelength of light absorbed in an electron transition from $n = 2$ to $n = 4$ in a hydrogen atom.

PRACTICE EXAMPLE B: Refer to Figure 8-14 and determine which transition produces the longest wavelength line in the Lyman series of the hydrogen spectrum. What is the wavelength of this line in nanometers and in angstroms?

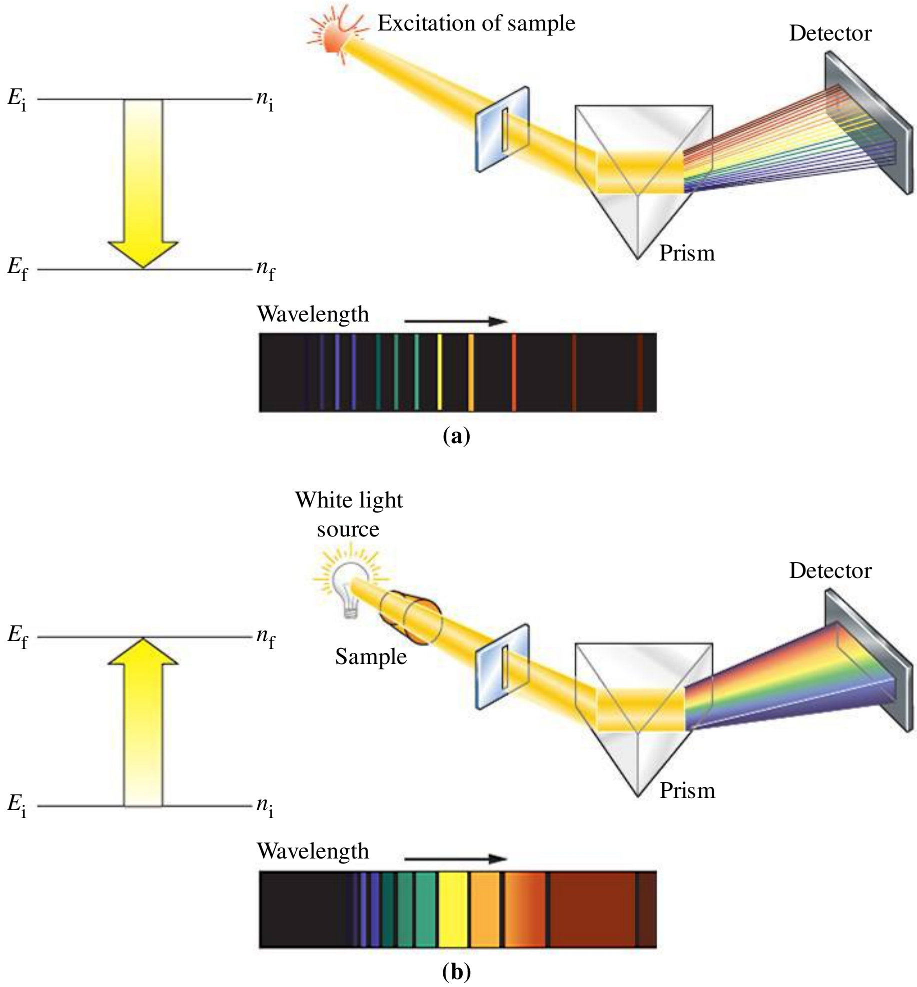
The Bohr Theory and Spectroscopy

As shown in Example 8-4, the Bohr theory provides a model for understanding the emission spectra of atoms. Emission spectra are obtained when the individual atoms in a collection of atoms (roughly 10^{20} of them) are excited to the various possible excited states of the atom. The atoms then relax to states of lower energy by emitting photons of frequency given by

$$\nu_{\text{photon}} = \frac{E_{\text{i}} - E_{\text{f}}}{h} \qquad (8.7)$$

Thus, the quantization of the energy states of atoms leads to line spectra.

Earlier in this chapter, we learned how the emission spectrum of a sample can be measured by dispersing emitted light through a prism and determining the wavelengths of the individual components of that light. We can conceive of an alternate technique in which we pass electromagnetic radiation, such as white light, through a sample of atoms in their ground states and then pass the emerging light through a prism. Now we observe which frequencies of light the atoms *absorb*. This form of spectroscopy is called *absorption spectroscopy*. The two types of spectroscopy—emission and absorption—are illustrated in Figure 8-15.



◀ FIGURE 8-15
Emission and absorption spectroscopy
(a) Emission spectroscopy. Bright lines are observed on a dark background of the photographic plate. **(b)** Absorption spectroscopy. Dark lines are observed on a bright background on the photographic plate.

For absorption of a photon to take place, the energy of the photon must exactly match the energy difference between the final and initial states, that is,

$$\nu = \frac{E_f - E_i}{h} \tag{8.8}$$

Note that the farther apart the energy levels, the shorter the wavelength of the photon needed to induce a transition.

You may have also noticed that in equation (8.7) the energy difference is expressed as $E_i - E_f$, whereas in equation (8.8) it is $E_f - E_i$. This is done to signify that energy is conserved during photon absorption and emission. That is, during emission $E_f = E_i - h\nu$, so that $\nu = (E_i - E_f)/h$. During photon absorption, $E_f = E_i + h\nu$, so that $\nu = (E_f - E_i)/h$.

Spectroscopic techniques have been used extensively in the study of molecular structures. Other forms of spectroscopy available to chemists are described elsewhere in the text.

Emission spectra are generally more complicated than absorption spectra. An excited sample will contain atoms in a variety of states, each being able to drop down to any of several lower states. An absorbing sample generally is cool and transitions are possible only from the ground state. The hydrogen Balmer lines are not seen, for example, in absorption from cold hydrogen atoms.

The Bohr Theory and the Ionization Energy of Hydrogen

The Bohr model of the atom helps to clarify the mechanism of formation of cations. In the special case where the energy of a photon interacting with a hydrogen atom is just enough to remove an electron from the ground state

$(n = 1)$, the electron is freed, the atom is ionized, and the energy of the free electron is zero.

$$h\nu_{\text{photon}} = E_{\text{i}} = -E_1$$

The quantity E_{i} is called the *ionization energy* of the hydrogen atom. If $n_{\text{i}} = 1$ and $n_{\text{f}} = \infty$ are substituted in the Bohr expression for an electron initially in the ground state of an H atom, then

$$h\nu_{\text{photon}} = E_{\text{i}} = -E_1 = \frac{R_{\text{H}}}{1^2} = R_{\text{H}}$$

The ideas just developed about the ionization of atoms are applied in Example 8-5, where they are coupled with another aspect of the Bohr model: The model also works for hydrogen-like species, such as the ions He^+ and Li^{2+}, which have only one electron. For these species, the nuclear charge (atomic number) appears in the energy-level expression. That is,

$$E_n = \frac{-Z^2 R_{\text{H}}}{n^2} \qquad \textbf{(8.9)}$$

Inadequacies of the Bohr Model

Despite the accomplishments of the Bohr model for the hydrogen atom and hydrogen-like ions, the Bohr theory has a number of weaknesses. From an experimental point of view, the theory cannot explain the emission spectra of atoms and ions with more than one electron, despite numerous attempts to do

EXAMPLE 8-5 Using the Bohr Model

Determine the kinetic energy of the electron ionized from a Li^{2+} ion in its ground state, using a photon of frequency $5.000 \times 10^{16}\ \text{s}^{-1}$.

Analyze

When a photon of a given energy ionizes a species, any excess energy is transferred as kinetic energy to the electron; that is, $E_{\text{photon}} = IE + KE_{\text{electron}}$. The energy of the electron in the Li^{2+} ion is calculated by using equation (8.9), and the energy of the photon is calculated by using Planck's relationship. The difference is the kinetic energy of the electron.

Solve

$$E_1 = \frac{-3^2 \times 2.179 \times 10^{-18}\ \text{J}}{1^2} = -1.961 \times 10^{-17}\ \text{J}$$

The energy of a photon of frequency $5.000 \times 10^{16}\ \text{s}^{-1}$ is

$$E = h\nu = 6.626 \times 10^{-34} \times \frac{\text{J s}}{\text{photon}} \times 5.000 \times 10^{16}\ \text{s}^{-1} = 3.313 \times 10^{-17}\ \text{J photon}^{-1}$$

The kinetic energy of the electron is given by $KE_{\text{electron}} = E_{\text{photon}} - IE$; that is,

$$\text{kinetic energy} = 3.313 \times 10^{-17}\ \text{J} - 1.961 \times 10^{-17}\ \text{J} = 1.352 \times 10^{-17}\ \text{J}$$

Assess

Notice the similarity between the energy conservation expression used in solving this problem ($E_{\text{photon}} = IE + KE_{\text{electron}}$) and the one used in explaining the photoelectric effect ($E_{\text{photon}} = eV_0 + KE_{\text{electron}}$).

PRACTICE EXAMPLE A: Determine the wavelength of light emitted in an electron transition from $n = 5$ to $n = 3$ in a Be^{3+} ion.

PRACTICE EXAMPLE B: The frequency of the $n = 3$ to $n = 2$ transition for an unknown hydrogen-like ion occurs at a frequency 16 times that of the hydrogen atom. What is the identity of the ion?

so. In addition, the theory cannot explain the effect of magnetic fields on emission spectra. From a fundamental standpoint, the Bohr theory is an uneasy mixture of classical and nonclassical physics. Bohr understood at the time that there is no fundamental basis for the postulate of quantized angular momentum forcing an electron into a circular orbit. He made the postulate only so that his theory would agree with experiment.

Modern quantum mechanics replaced the Bohr theory in 1926. The quantization of energy and angular momentum arose out of the postulates of this new quantum theory and required no extra assumptions. Moreover, the circular orbits of the Bohr theory do not occur in quantum mechanics. In summary, the Bohr theory gave the paradigm shift—the quantum leap—from classical physics to the new quantum physics, and we must not underestimate its importance as a scientific development.

8-4 CONCEPT ASSESSMENT

Which of the following electronic transitions in a hydrogen atom will lead to the emission of a photon with the shortest wavelength, $n = 1$ to $n = 4$, $n = 4$ to $n = 2$, $n = 3$ to $n = 2$?

8-5 Two Ideas Leading to a New Quantum Mechanics

In the previous section, we examined some successes of the Bohr theory and pointed out its inability to deal with multielectron atoms. A decade or so after Bohr's work on hydrogen, two landmark ideas stimulated a new approach to quantum mechanics. Those ideas are considered in this section and the new quantum mechanics—wave mechanics—in the next.

Wave–Particle Duality

To explain the photoelectric effect, Einstein suggested that light has particle-like properties, which are displayed through photons. Other phenomena, however, such as the dispersion of light into a spectrum by a prism, are best understood in terms of the wave theory of light. Light, then, appears to have a *dual* nature.

In 1924, Louis de Broglie, considering the nature of light and matter, offered a startling proposition: *Small particles of matter may at times display wave-like properties*. How did de Broglie come up with such a suggestion? He was aware of Einstein's famous equation

$$E = mc^2$$

where m is the relativistic mass of the photon and c is the speed of light. He combined this equation with the Planck relationship for the energy of a photon $E = h\nu$ as follows

$$h\nu = mc^2$$

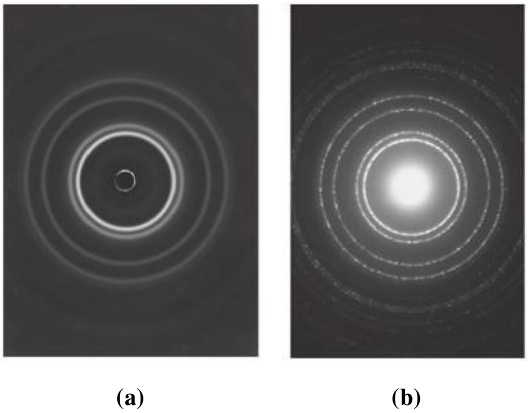
$$\frac{h\nu}{c} = mc = p$$

where p is the momentum of the photon. Using $\nu\lambda = c$, we have

$$p = \frac{h}{\lambda}$$

In order to use this equation for a material particle, such as an electron, de Broglie substituted for the momentum, p, its equivalent—the product of the

▲ **Louis de Broglie (1892–1987)**
De Broglie conceived of the wave–particle duality of small particles while working on his doctorate degree. He was awarded the Nobel Prize in physics 1929 for this work.



(a) (b)

▶ FIGURE 8-16
Wave properties of electrons demonstrated.

(b) Diffraction of electrons by metal foil, confirming the wave-like properties of electrons.

KEEP IN MIND

that in equation (8.10), wavelength is in meters, mass is in kilograms, and velocity is in meters per second. Planck's constant must also be expressed in units of mass, length, and time. This requires replacing the joule by the equivalent units kg $m^2 s^{-2}$.

mass of the particle, *m*, and its velocity, *u*. When this is done, we arrive at de Broglie's famous relationship.

$$\lambda = \frac{h}{p} = \frac{h}{mu} \tag{8.10}$$

De Broglie called the waves associated with material particles "matter waves." If matter waves exist for small particles, then beams of particles, such as electrons, should exhibit the characteristic properties of waves, namely diffraction (recall page 298). If the distance between the objects that the waves scatter from is about the same as the wavelength of the radiation, diffraction occurs and an interference pattern is observed. For example, X-rays are highly energetic photons with an associated wavelength of about 1 Å (100 pm). X-rays are scattered by the regular array of atoms in the metal aluminum, where the atoms are about 2 Å (200 pm) apart, producing the diffraction pattern shown in Figure 8-16.

In 1927, C. J. Davisson and L. H. Germer of the United States showed that a beam of slow electrons is diffracted by a crystal of nickel. In a similar experiment in that same year, G. P. Thomson of Scotland directed a beam of electrons at a thin metal foil. He obtained the same pattern for the diffraction of electrons by aluminum foil as with X-rays of the same wavelength (Fig. 8-16).

Thomson and Davisson shared the 1937 Nobel Prize in physics for their electron diffraction experiments. George P. Thomson was the son of J.J. Thomson, who had won the Nobel Prize in physics in 1906 for his discovery of the electron. It is interesting to note that Thomson the father showed that the electron is a particle, and Thomson the son showed that the electron is a wave. Father and son together demonstrated the **wave–particle duality** of electrons.

The wavelength calculated in Example 8-6, 24.2 pm, is about one-half the radius of the first Bohr orbit of a hydrogen atom. It is only when wavelengths are comparable to atomic or nuclear dimensions that wave–particle duality is important. The concept has little meaning when applied to large (macroscopic) objects, such as baseballs and automobiles, because their wavelengths are too small to measure. For these macroscopic objects, the laws of classical physics are quite adequate.

The Uncertainty Principle

The laws of classical physics permit us to make precise predictions. For example, we can calculate the exact point at which a rocket will land after it is fired. The more precisely we measure the variables that affect the rocket's trajectory (path), the more accurate our calculation (prediction) will be. In effect, there is no limit to the accuracy we can achieve. In classical physics, nothing is left to chance—physical behavior can be predicted with certainty.

EXAMPLE 8-6 Calculating the Wavelength Associated with a Beam of Particles

What is the wavelength associated with electrons traveling at one-tenth the speed of light?

Analyze

To calculate the wavelength, we use equation (8.10). To use it, we have to collect the electron mass, the electron velocity, and Planck's constant, and then adjust the units so that they are expressed in terms of kg, m, and s.

Solve

The electron mass, expressed in kilograms, is 9.109×10^{-31} kg (recall Table 2.1).
The electron velocity is $u = 0.100 \times c = 0.100 \times 3.00 \times 10^{8}\ \text{m s}^{-1} = 3.00 \times 10^{7}\ \text{m s}^{-1}$.
Planck's constant $h = 6.626 \times 10^{-34}\ \text{J s} = 6.626 \times 10^{-34}\ \text{kg m}^2\,\text{s}^{-2}\,\text{s} = 6.626 \times 10^{-34}\ \text{kg m}^2\,\text{s}^{-1}$.
Substituting these data into equation (8.10), we obtain

$$\lambda = \frac{6.626 \times 10^{-34}\ \text{kg m}^2\,\text{s}^{-1}}{(9.109 \times 10^{-31}\ \text{kg})(3.00 \times 10^{7}\ \text{m s}^{-1})}$$
$$= 2.42 \times 10^{-11}\ \text{m} = 24.2\ \text{pm}$$

Assess

By converting the unit J to kg $\text{m}^2\,\text{s}^{-2}$, we are able to obtain the wavelength in meters.

PRACTICE EXAMPLE A: Assuming Superman has a mass of 91 kg, what is the wavelength associated with him if he is traveling at one-fifth the speed of light?

PRACTICE EXAMPLE B: To what velocity (speed) must a beam of protons be accelerated to display a de Broglie wavelength of 10.0 pm? Obtain the proton mass from Table 2.1.

During the 1920s, Niels Bohr and Werner Heisenberg considered hypothetical experiments to establish just how precisely the behavior of subatomic particles can be determined. The two variables that must be measured are the position of the particle (x) and its momentum $(p = mu)$. The conclusion they reached is that there must *always* be uncertainties in measurement such that the product of the uncertainty in position, Δx, and the uncertainty in momentum, Δp, is

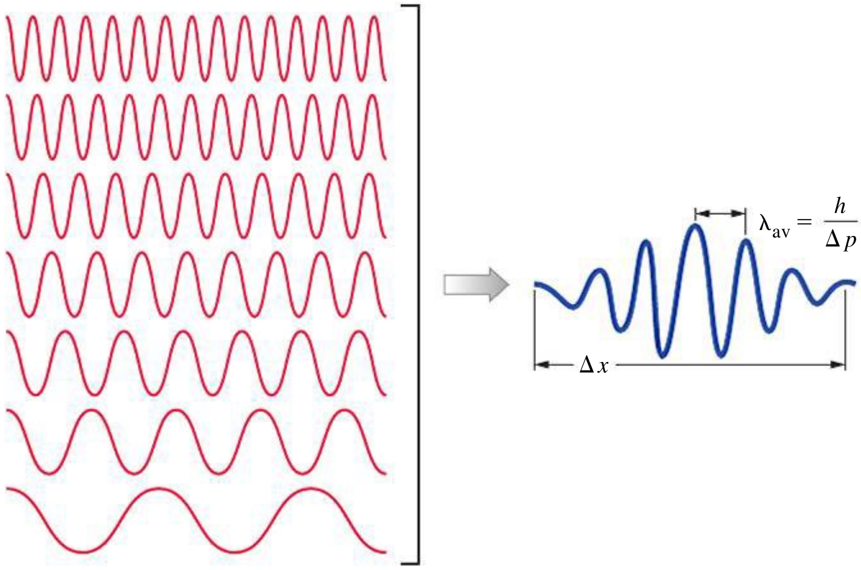
$$\Delta x \Delta p \geq \frac{h}{4\pi} \tag{8.11}$$

The significance of this expression, called the **Heisenberg uncertainty principle**, is that we cannot measure position and momentum with great precision simultaneously. An experiment designed to locate the position of a particle with great precision cannot also measure the momentum of the particle precisely, and vice versa. In simpler terms, if we know precisely where a particle is, we cannot also know precisely where it has come from or where it is going. If we know precisely how a particle is moving, we cannot also know precisely where it is. In the subatomic world, things must always be "fuzzy." Why should this be so?

The de Broglie relationship (equation 8.10) implies that for a wavelength λ, the momentum of the associated particle is precisely known. However, since the wave itself is spread out over all space, we do not know exactly where the particle is! To get around this inability to locate the particle, we can combine several waves of different wavelengths into a "wave packet" to produce an interference pattern that tends to localize the wave, as suggested in Figure 8-17. However, because each wavelength in the wave packet corresponds to a specific, but different, momentum, the momentum of the particle corresponding to the collection of waves has become uncertain. So as we combine more and more waves to localize the particle, the momentum becomes more and more uncertain. And, conversely, the more precisely we want to know the momentum of a particle the fewer and fewer wavelengths we should combine, meaning that the position

▲ **Werner Heisenberg (1901–1976)**
In addition to his enunciation of the uncertainty principle, for which he won the Nobel Prize in physics in 1932, Heisenberg also developed a mathematical description of the hydrogen atom that gave the same results as Schrödinger's equation (page 323). Heisenberg (left) is shown here dining with Niels Bohr.

▶ The uncertainty principle is not easy for most people to accept. Einstein spent a good deal of time from the middle 1920s until his death in 1955 attempting, unsuccessfully, to disprove it.



▲ FIGURE 8-17
The uncertainty principle interpreted graphically
A collection of waves with varying wavelengths (left) can combine into a "wave packet" (right). The superposition of the different wavelengths yields an average wavelength (λ_{av}) and causes the wave packet to be more localized (Δx) than the individual waves. The greater the number of wavelengths that combine, the more precisely an associated particle can be located, that is, the smaller Δx. However, because each of the wavelengths corresponds to a different value of momentum according to the de Broglie relationship, the greater is the uncertainty in the resultant momentum.

becomes more spread out. Thus as we proceed downward in size to atomic dimensions, it is no longer valid to consider a particle to be like a hard sphere. Instead, it becomes more and more wavelike, and it is no longer possible to determine with precision both its position and its momentum.

Once we understand that the consequence of wave–particle duality is the uncertainty principle, we realize that a fundamental error of the Bohr model was to constrain an electron to a one-dimensional orbit (1-D in the sense that the electron cannot move off a circular path of a fixed radius). We are now ready to turn our attention to a modern description of electrons in atoms.

The unit electron-volt (eV). One electron-volt is the energy acquired by an electron as it falls through an electric potential difference of 1 volt. ▼

EXAMPLE 8-7 Calculating the Uncertainty of the Position of an Electron

A 12 eV electron can be shown to have a speed of 2.05×10^6 m/s. Assuming that the precision (uncertainty) of this value is 1.5%, with what precision can we simultaneously measure the position of the electron?

Analyze

When given an uncertainty as a percentage, we have to convert it to a fraction by dividing by 100%. The uncertainty of the velocity is then obtained by multiplying this number by the actual velocity.

Solve

The uncertainty in the electron speed is

$$\Delta u = 0.015 \times 2.05 \times 10^6 \text{ m s}^{-1} = 3.1 \times 10^4 \text{ m s}^{-1}$$

The electron mass, 9.109×10^{-31} kg (recall Table 2.1), is known much more precisely than the electron speed, which means that

$$\begin{aligned}\Delta p = m\Delta u &= 9.109 \times 10^{-31} \text{ kg} \times 3.1 \times 10^4 \text{ m s}^{-1} \\ &= 2.8 \times 10^{-26} \text{ kg m s}^{-1}\end{aligned}$$

From equation (8.11), the uncertainty in the electron's position is

$$\Delta x = \frac{h}{4\pi\Delta p} = \frac{6.63 \times 10^{-34}\,\text{kg m}^2\,\text{s}^{-1}}{4 \times 3.14 \times 2.8 \times 10^{-26}\,\text{kg m s}^{-1}} = 1.9 \times 10^{-9}\,\text{m} = 1.9 \times 10^{3}\,\text{pm}$$

Assess

The uncertainty of the electron's position is about 10 atomic diameters. Given the uncertainty in its speed, there is no way to pin down the electron's position with any greater precision.

PRACTICE EXAMPLE A: Superman has a mass of 91 kg and is traveling at one-fifth the speed of light. If the speed at which Superman travels is known with a precision of 1.5%, what is the uncertainty in his position?

PRACTICE EXAMPLE B: What is the uncertainty in the speed of a beam of protons whose position is known with the uncertainty of 24 nm?

8-5 CONCEPT ASSESSMENT

An electron has a mass approximately 1/2000th of the mass of a proton. Assuming that a proton and an electron have similar wavelengths, how would their speeds compare?

8-6 Wave Mechanics

De Broglie's relationship suggests that electrons are matter waves and thus should display wavelike properties. A consequence of this wave–particle duality is the limited precision in determining an electron's position and momentum imposed by the Heisenberg uncertainty principle. How then are we to view electrons in atoms? To answer this question, we must begin by identifying two types of waves.

Standing Waves

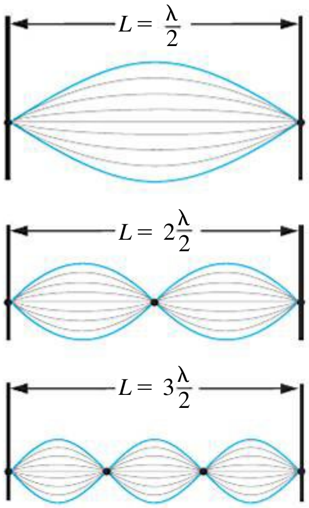
On an ocean, the wind produces waves on the surface whose crests and troughs travel great distances. These are called *traveling waves*. In the traveling wave shown in Figure 8-1, every portion of a very long rope goes through an identical up-and-down motion. The wave transmits energy along the entire length of the rope. An alternative form of a wave is seen in the vibrations in a plucked guitar string, suggested by Figure 8-18.

Segments of the string experience up-and-down displacements with time, and they oscillate or vibrate between the limits set by the blue curves. The important aspect of these waves is that the crests and troughs of the wave occur at fixed positions and the amplitude of the wave at the fixed ends is zero. Of special interest is the fact that the magnitudes of the oscillations differ from point to point along the wave, including certain points, called *nodes*, that undergo no displacement at all. A wave with these characteristics is called a **standing wave**.

We might say that the permitted wavelengths of standing waves are quantized. They are equal to twice the path length (L) divided by a whole number (n), that is,

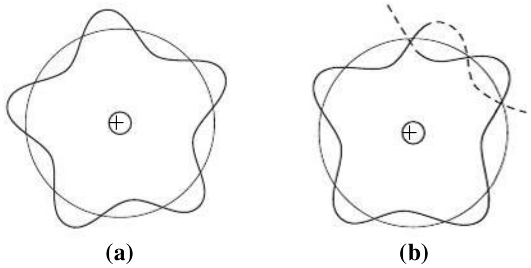
$$\lambda = \frac{2L}{n} \quad \text{where } n = 1, 2, 3, \ldots \text{and the total number of nodes} = n + 1 \qquad \textbf{(8.12)}$$

The plucked guitar string represents a one-dimensional standing wave, and so does an electron in a Bohr orbit. Bohr surmised that for an electron to be stable in a circular orbit, it has to be represented by a standing wave and that an integral number of wavelengths have to fit the circumference of the orbit (Fig. 8-19). Also, the fact that Bohr orbits are one dimensional (they are defined by a single



▲ FIGURE 8-18
Standing waves in a string
The string can be set into motion by plucking it. The blue boundaries outline the range of displacements at each point for each standing wave. The relationships between the wavelength, string length, and the number of nodes—points that are not displaced—are given by equation (8.12). The nodes are marked by bold dots.

▶ Beating a drum produces a two-dimensional standing wave, and ringing a spherical bell produces a three-dimensional standing wave.



▲ FIGURE 8-19
The electron as a matter wave
These patterns are two-dimensional cross-sections of a much more complicated three-dimensional wave. The wave pattern in **(a)**, a *standing wave*, is an acceptable representation. It has an integral number of wavelengths (five) about the nucleus; successive waves reinforce one another. The pattern in **(b)** is unacceptable. The number of wavelengths is nonintegral, and successive waves tend to cancel each other; that is, the crest in one part of the wave overlaps a trough in another part of the wave, and there is no resultant wave at all.

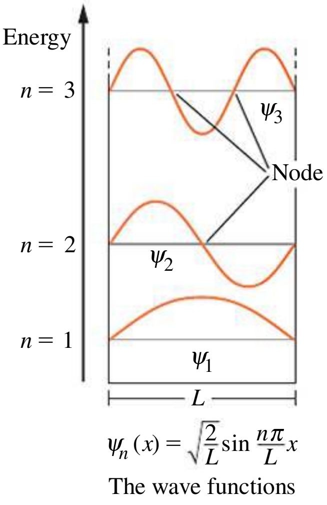
dimension, the radius) also points up a serious deficiency in the Bohr model: The matter waves of electrons in the hydrogen atom must be three dimensional.

KEEP IN MIND

that a circle is one dimensional in the sense that all points on the circumference are at the same distance from the center. Thus, only one value needs to be given to define a circle—its radius.

Particle in a Box: Standing Waves, Quantum Particles, and Wave Functions

In 1927, Erwin Schrödinger, an expert on the theory of vibrations and standing waves, suggested that an electron (or any other particle) exhibiting wavelike properties should be describable by a mathematical equation called a **wave function**. The wave function, denoted by the Greek letter psi, ψ, should correspond to a standing wave within the boundary of the system being described. The simplest system for which we can write a wave function is another one-dimensional system, that of a quantum particle confined to move in a one-dimensional box, a line. The wave function for this so-called "particle in a box" looks like those of a guitar string (Fig. 8-18), but now it represents the matter waves of a particle. Since the particle is constrained to be in the box, the waves also must be in the box, as illustrated in Figure 8-20.



▲ FIGURE 8-20
The standing waves of a particle in a one-dimensional box
The first three wave functions and their energies are shown in relation to the position of the particle within the box. The wave function changes sign at the nodes.

If the length of the box is L and the particle moves along the x direction, then the equation for the standing wave is

$$\psi_n(x) = \sqrt{\frac{2}{L}}\sin\left(\frac{n\pi x}{L}\right) \quad n = 1, 2, 3, \ldots \tag{8.13}$$

where the quantum number, n, labels the wave function.

This wave function is a sine function. To illustrate, consider the case where $n = 2$.

When

$x = 0,$	$\sin 2\pi x/L = \sin 0 = 0,$	and $\psi_n(x) = 0$
$x = L/4,$	$\sin 2\pi(L/4)/L = \sin \pi/2 = 1,$	and $\psi_n(x) = (2/L)^{1/2}$
$x = L/2,$	$\sin 2\pi(L/2)/L = \sin \pi = 0,$	and $\psi_n(x) = 0$
$x = 3L/4$	$\sin 2\pi(3L/4)/L = \sin 3\pi/2 = -1$	and $\psi_n(x) = -(2/L)^{1/2}$
$x = L$	$\sin 2\pi(L)/L = \sin 2\pi = 0,$	and $\psi_n(x) = 0$

At one end of the box ($x = 0$), both the sine function and the wave function are zero. At one-fourth the length of the box ($x = L/4$), the sine function and the wave function both reach their maximum values. At the midpoint of the box, both are again zero; the wave function has a node. At three-fourths the box length, both functions reach their minimum values (negative quantities), and at the farther end of the box, both functions are again zero.

8-4 ARE YOU WONDERING...

How did we arrive at Equation (8.13)?

The answer to how we arrived at equation (8.13) lies in the equation that gives the form of the wave function and the boundaries to which the quantum mechanical particle is confined. The particle-in-a-box model assumes that the electron is free in the box but is unable to get out of the box. This means that the wave function will be a standing wave inside the box. If you are familiar with differential calculus, you will recognize the equation below as a differential equation. Specifically, it describes a one-dimensional standing wave for the simple system of a particle in a box. The solution to this equation is the wave function for the system.

$$\frac{d^2\psi}{dx^2} = -\left(\frac{2\pi}{\lambda}\right)^2\psi$$

Notice the form of the wave equation: By differentiating the wave function twice, we obtain the wave function times a constant. Many functions satisfy this requirement. For example, two trigonometric functions that have this property are the sine and cosine functions. First, let us consider the function $\psi = A\cos(ax)$ and differentiate twice with respect to x:

$$\frac{d\psi}{dx} = -aA\sin(ax)$$
$$\frac{d^2\psi}{dx^2} = -a^2A\cos(ax) = -a^2\psi$$

where we can identify $a = (2\pi/\lambda)$ and A is an arbitrary factor to be determined. Second, for the sine function,

$$\frac{d\psi}{dx} = aA\cos(ax)$$
$$\frac{d^2\psi}{dx^2} = -a^2A\sin(ax) = -a^2\psi$$

Therefore, both functions are acceptable from this point of view. However, the function must form a standing wave in the box, with a value of zero at the edges of the box. When $x = 0$, $\cos 0 = 1$ and $\sin 0 = 0$, and so the sine function is the appropriate function. The determination of A is not quite as straightforward, and we need to know how to interpret the wave function to determine the value of A. In carrying out this procedure, we have used the boundary conditions of the system to help decide on the correct form of the wave function, which is a common procedure when solving quantum mechanical problems.

Finally, if we identify $a = (2\pi/\lambda)$ and use the standing wave requirement in equation (8.12), then

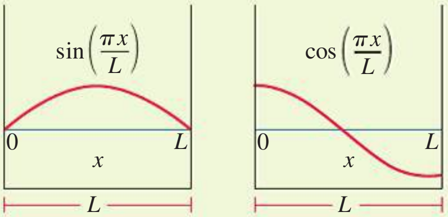
$$a = \frac{2\pi}{\lambda} = \frac{2\pi}{2L/n} = \frac{n\pi}{L}$$

and the function is

$$\psi_n = A\sin\left(\frac{n\pi x}{L}\right)$$

where n is identified as a quantum number, $n = 1, 2, 3, 4, \ldots$

(continued)



▲ Illustration of why a cosine function is an unacceptable solution for the particle in a box. The sine function correctly goes to zero at the edge of the box, but the cosine function does not.

What sense can we make of the wave function and the quantum number? First, consider the quantum number, n. What can we relate it to? The particle that we are considering is freely moving (not acted upon by any outside forces) with a kinetic energy given by the expression

$$E_k = \frac{1}{2}mu^2 = \frac{m^2u^2}{2m} = \frac{p^2}{2m} \tag{8.14}$$

Now, to associate this kinetic energy with a wave, we can use de Broglie's relationship $(\lambda = h/p)$ to get

$$E_k = \frac{p^2}{2m} = \frac{h^2}{2m\lambda^2}$$

The wavelengths of the matter wave have to fit the standing wave conditions described earlier for the standing waves of a guitar string (equation 8.12). Substituting the wavelength of the matter wave from equation (8.12) into the equation for the energy of the wave yields

$$E_k = \frac{h^2}{2m\lambda^2} = \frac{h^2}{2m(2L/n)^2} = \frac{n^2h^2}{8mL^2}$$

So we see that the standing wave condition naturally gives rise to quantization of the wave's energy, with the allowable values determined by the value of n. Note also that as we decrease the size of the box, the kinetic energy of the particle increases, and according to the uncertainty principle, our knowledge of the momentum must decrease. A final noteworthy point is that the energy of the particle *cannot be zero*. The lowest possible energy, corresponding to $n = 1$, is called the **zero-point energy**. Because the zero-point energy is not zero, the particle cannot be at rest. This observation is consistent with the uncertainty principle because the position and momentum both must be uncertain, and there is nothing uncertain about a particle at rest.

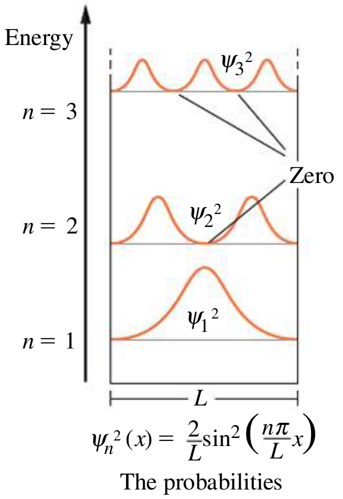
The particle-in-a-box model helps us see the origin of the quantization of energy, but how are we to interpret the wave function, ψ? What does it mean that the value of the wave function can be positive or negative? Actually, unlike the trajectory of a classical particle, the wave function of a particle has no physical significance. We need to take a different approach, one suggested by the German physicist Max Born in 1926. From the electron-as-particle standpoint, we have a special interest in the *probability* that the electron is at some particular point; from the electron-as-wave standpoint, our interest is in *electron charge density*. In a classical wave (such as visible light), the amplitude of the wave corresponds to ψ, and the intensity of the wave to ψ^2. The intensity relates to the photon density—the number of photons present in a region. For an electron wave, then, ψ^2 relates to electron charge density. Electron probability is proportional to electron charge density, and both these quantities are associated with ψ^2. Thus, in Born's interpretation of the wave function, the total probability of finding an electron in a small volume of space is the product of the square of the wave function, ψ^2, and the volume of interest. The factor ψ^2 is called the electron probability density.

Now let us return to a particle constrained to a one-dimensional path in a box and look at the probabilities for the wave functions. These are shown in Figure 8-21. First, notice that even where the wave function is negative, the probability density is positive, as it should be in all cases. Next, look at the probability density for the wave function corresponding to $n = 1$. The highest value of ψ^2 is at the center of the box; that is, the particle is most likely to be found there. The probability density for the state with $n = 2$ indicates that the particle is most likely to be found between the center of the box and the walls.

A final consideration of the particle-in-a-box model concerns its extension to a three-dimensional box. In this case, the particle can move in all three directions—x, y, and z—and the quantization of energy is described by the following expression.

$$E_{n_x n_y n_z} = \frac{h^2}{8m}\left[\frac{n_x^2}{L_x^2} + \frac{n_y^2}{L_y^2} + \frac{n_z^2}{L_z^2}\right]$$

where there is one quantum number for each dimension. Thus, a three-dimensional system needs three quantum numbers. With these particle-in-a-box ideas, we can now discuss solving the quantum mechanical problem of the hydrogen atom.



▲ FIGURE 8-21
The probabilities of a particle in a one-dimensional box
The squares of the first three wave functions and their energies are shown in relation to the position of the particle within the box. There is no chance of finding the particle at the points where $\psi^2 = 0$.

EXAMPLE 8-8 Using the Wave Functions of a Particle in a One-Dimensional Box

What is the fraction, as a percentage, of the total probability of finding, between points at 0 pm and 30 pm, an electron in the $n = 5$ level of a one-dimensional box 150 pm long?

Analyze

If an electron is in the $n = 5$ level, then we have a 100% chance of finding it in that level. The $n = 5$ wave function has 4 nodes 30 pm apart, and there are five maxima in ψ^2 at 15 pm, 45 pm, 75 pm, 105 pm, and 135 pm for a one-dimensional box 150 pm long.

Solve

The position at 30 pm corresponds to a node in the wave function, and there are four of these (not counting the nodes at each end of the box). The total area between 0 and 30 pm of ψ^2 represents 25% of the total probability, and so between 0 pm and 30 pm, we expect to find 25% of the probability.

Assess

We must remember that the particle we are considering exhibits wave–particle duality, making it inappropriate to ask a question about how it gets from one side of the node to the other (but that is an appropriate question for a *classical* particle). All we know is that in the $n = 5$ state, for example, the particle is in the box somewhere. When we make a measurement, we'll find the particle on one side of a node or the other. Between 0 and 30 pm, we have a 25% chance of finding the particle, and the maximum chance occurs at 15 pm.

PRACTICE EXAMPLE A: What is the fraction, as a percentage of the total probability of finding, between points at 50 pm and 75 pm, an electron in the $n = 6$ level of a one-dimensional box 150 pm long?

PRACTICE EXAMPLE B: A particle is confined to a one-dimensional box 300 pm long. For the state having $n = 3$, at what points (not counting the ends of the box) does the particle have zero probability of being found?

EXAMPLE 8-9 Calculating Transition Energy and Photon Wavelengths for the Particle in a Box

What is the energy difference between the ground state and the first excited state of an electron contained in a one-dimensional box 1.00×10^2 pm long? Calculate the wavelength of the photon that could excite the electron from the ground state to the first excited state.

Analyze

The energy of an electron (E_n) in level n is

$$E_n = \frac{n^2h^2}{8mL^2}$$

We can write expressions for E_n and E_{n+1}, subtract them, and then substitute the values for h, m, and L. The ground state corresponds to $n = 1$, and the first excited state corresponds to $n = 2$. Finally, we can calculate the wavelength of the photon from the Planck relationship and $c = \lambda\nu$.

Solve

The energies for the states $n = 1$ and $n = 2$ are

$$E_{\text{ground state}} = E_1 = \frac{h^2}{8mL^2}(1^2)$$

$$E_{\text{first excited state}} = E_2 = \frac{h^2}{8mL^2}(2^2)$$

The energy difference is

$$\Delta E = E_2 - E_1 = \frac{3h^2}{8mL^2}$$

The electron mass is 9.109×10^{-31} kg, Planck's constant $h = 6.626 \times 10^{-34}$ J s, and the length of the box is 1.00×10^{-10} m. (Recall: 1 pm $= 10^{-12}$ m.) Substituting these data into the equation, we obtain

$$\Delta E = \frac{3(6.626 \times 10^{-34}\,\text{J s})^2}{8(9.109 \times 10^{-31}\,\text{kg})(1.00 \times 10^{-10}\,\text{m})^2}$$
$$= 1.81 \times 10^{-17}\,\text{J}$$

By using Planck's constant and this value as the energy of a photon, we can calculate the frequency of the photon and then the wavelength. Combining these steps,

$$\lambda = \frac{hc}{E_{\text{photon}}} = \frac{hc}{\Delta E} = \frac{6.626 \times 10^{-34}\,\text{J s} \times 3.00 \times 10^{8}\,\text{m s}^{-1}}{1.81 \times 10^{-17}\,\text{J}} = 11.0 \times 10^{-9}\,\text{m} = 11.0\,\text{nm}$$

Assess

If we needed the energy of the photon in kJ mol^{-1}, we would have had to multiply 1.8×10^{-17} J by 10^{-3} k J/J and $N_A = 6.022 \times 10^{23}\,\text{mol}^{-1}$.

PRACTICE EXAMPLE A: Calculate the wavelength of the photon emitted when an electron in a box 5.0×10^1 pm long falls from the $n = 5$ level to the $n = 3$ level.

PRACTICE EXAMPLE B: A photon of wavelength 24.9 nm excites an electron in a one-dimensional box from the ground state to the first excited state. Estimate the length of the box.

8-6 CONCEPT ASSESSMENT

For a particle in a one-dimensional box, in which state (value of n) is the greatest probability of finding the particle at one-quarter the length of the box from either end?

Wave Functions of the Hydrogen Atom

In 1927, Schrödinger showed that the wave functions of a quantum mechanical system can be obtained by solving a wave equation that has since become known as the **Schrödinger equation**. We will not go into the details of its

8-5 ARE YOU WONDERING...

What is the Schrödinger equation for the hydrogen atom?

To obtain the Schrödinger equation, we start with the equation for a standing wave in one dimension:

$$\frac{d^2\psi}{dx^2} = -\left(\frac{2\pi}{\lambda}\right)^2 \psi$$

The next step is to substitute de Broglie's relationship for the wavelength of a matter wave.

$$\frac{d^2\psi}{dx^2} = -\left(\frac{2\pi}{h} p\right)^2 \psi$$

Finally, we use the relationship between momentum and kinetic energy, equation 8.14, to obtain

$$-\frac{h^2}{8\pi^2 m}\frac{d^2\psi}{dx^2} = E_k\psi$$

This is the Schrödinger equation of a free particle moving in one dimension. If the particle is subjected to a force, $V(x)$, then we have

$$-\frac{h^2}{8\pi^2 m}\frac{d^2\psi}{dx^2} + V(x)\psi = E_{\text{total}}\psi$$

Extending this treatment to three dimensions, we obtain the Schrödinger equation for the hydrogen atom or hydrogen-like ion, where we understand $V(r)$ to be $(-e)(Ze)/4\pi\epsilon_0 r)$, the potential energy associated with the interaction of the electron (charge $= -e$), and the nucleus of the one electron atom or ion (charge = Ze). (See Appendix B, page B-4.)

$$-\frac{h^2}{8\pi^2 m_e}\left(\frac{\partial^2\psi}{\partial x^2} + \frac{\partial^2\psi}{\partial y^2} + \frac{\partial^2\psi}{\partial z^2}\right) - \frac{Ze^2}{r}\psi = E\psi$$

This is the equation that Schrödinger obtained. In the equation above, $\partial^2\psi/\partial x^2$ means that we differentiate ψ twice with respect to x, treating the other variables (y and z) as constants. The notation $\partial^2\psi/\partial x^2$ is used instead of $d^2\psi/dx^2$ because ψ depends on more than one variable.

Following a suggestion by Eugene Wigner, Schrödinger used spherical polar coordinates to solve it rather than the Cartesian coordinates shown here. That is, he substituted the values of x, y, and z in terms of spherical polar coordinates given in the caption for Figure 8-22 and performed the necessary lengthy algebra to collect the variables r, θ, and ϕ. The equation he obtained is

$$-\frac{h^2}{8\pi^2 \mu r^2}\left[\frac{\partial}{\partial r}\left(r^2\frac{\partial\psi}{\partial r}\right) + \frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial\psi}{\partial\theta}\right) + \frac{1}{\sin^2\theta}\frac{\partial^2\psi}{\partial\phi^2}\right] - \frac{Ze^2}{r}\psi = E\psi$$

where the mass of the electron has been replaced by the more correct reduced mass of the atom, μ, given by

$$\frac{1}{\mu} = \frac{1}{m_e} + \frac{1}{m_{\text{nucleus}}}$$

This is the Schrödinger equation in spherical polar coordinates for a hydrogen-like ion of atomic number Z or the hydrogen atom if $Z = 1$. The solutions are shown in Table 8.1 on page 327.

solution but just describe and interpret the solution using ideas introduced in the previous discussion.

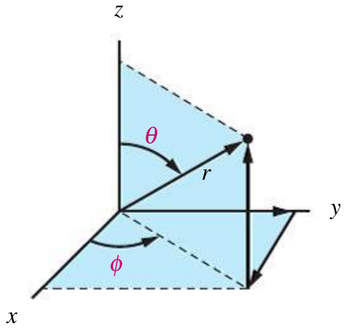
Solutions of the Schrödinger equation for the hydrogen atom give the wave functions for the electron in the hydrogen atom. These wave functions are called **orbitals** to distinguish them from the orbits of the Bohr theory. The mathematical form of these orbitals is more complex than for the particle in a box, but nonetheless they can be interpreted in a straightforward way.

Wave functions are most easily analyzed in terms of the three variables required to define a point with respect to the nucleus. In the usual Cartesian coordinate system, these three variables are the x, y, and z dimensions. In the spherical polar coordinate system, they are r, the distance of the point from the nucleus, and the angles θ (theta) and ϕ (phi), which describe the orientation of the distance line, r, with respect to the x, y, and z axes (Fig. 8-22). Either coordinate system could be used in solving the Schrödinger equation. However, whereas in the Cartesian coordinate system the orbitals would involve all three variables, x, y, and z, in the spherical polar system the orbitals can be expressed in terms of one function R that depends only on r, and a second function Y that depends on θ and ϕ. That is,

$$\psi(r, \theta, \phi) = R(r)Y(\theta, \phi)$$

The function $R(r)$ is called the **radial wave function**, and the function $Y(\theta, \phi)$ is called the **angular wave function**. Each orbital has three quantum numbers to define it since the hydrogen atom is a three-dimensional system. The particular set of quantum numbers confers a particular functional form to $R(r)$ and $Y(\theta, \phi)$.

Probability densities and the spatial distribution of these densities can be derived from these functional forms. We will first discuss quantum numbers and the orbitals they define, and then the distribution of probability densities associated with the orbitals.



Spherical polar coordinates

$x^2 + y^2 + z^2 = r^2$

$x = r \sin\theta \cos\phi$

$y = r \sin\theta \sin\phi$

$z = r \cos\theta$

▲ FIGURE 8-22
The relationship between spherical polar coordinates and Cartesian coordinates
The coordinates x, y, and z are expressed in terms of the distance r and the angles θ and ϕ.

8-7 Quantum Numbers and Electron Orbitals

In the preceding section we stated that by specifying three quantum numbers in a wave function ψ, we obtain an orbital. Here, we explore the combinations of quantum numbers that produce different orbitals. First, though, we need to learn more about the nature of these three quantum numbers.

Assigning Quantum Numbers

The following relationships involving the three quantum numbers arise from the solution of the Schrödinger wave equation for the hydrogen atom. In this solution the values of the quantum numbers are fixed *in the order listed.*

The first number to be fixed is the *principal quantum number*, n, which may have only a positive, nonzero integral value.

$$n = 1, 2, 3, 4, \ldots \qquad (8.15)$$

Second is the *orbital angular momentum quantum number*, ℓ, which may be zero or a positive integer, but not larger than $n - 1$ (where n is the principal quantum number).

$$\ell = 0, 1, 2, 3, \ldots, n - 1 \qquad (8.16)$$

Third is the *magnetic quantum number*, m_ℓ, which may be a negative or positive integer, including zero, and ranging from $-\ell$ to $+\ell$ (where ℓ is the orbital angular momentum quantum number).

$$m_\ell = -\ell, (-\ell + 1), \ldots, -2, -1, 0, 1, 2 \ldots, (\ell - 1), +\ell \qquad (8.17)$$

EXAMPLE 8-10 Applying Relationships Among Quantum Numbers

Can an orbital have the quantum numbers $n = 2, \ell = 2$, and $m_\ell = 2$?

Analyze

We must determine whether the given set of quantum numbers is allowed by the rules expressed in equations (8.15), (8.16), and (8.17).

Solve

No. The ℓ quantum number cannot be greater than $n - 1$. Thus, if $n = 2$, ℓ can be only 0 or 1. And if ℓ can be only 0 or 1, m_ℓ cannot be 2; m_ℓ must be 0 if $\ell = 0$ and may be $-1, 0$, or $+1$ if $\ell = 1$.

Assess

It is important that we remember the physical significance of the various quantum numbers, as well as the rules interrelating their values. Quantum number n determines the radial distribution and the average *distance* of the electron and, thus, is most important in determining the *energy* of an electron. Quantum number ℓ determines the angular distribution or *shape* of an orbital. As we will soon see, the relationships among the quantum numbers impart a logical organization of orbitals into shells and subshells.

PRACTICE EXAMPLE A: Can an orbital have the quantum numbers $n = 3, \ell = 0$, and $m_\ell = 0$?

PRACTICE EXAMPLE B: For an orbital with $n = 3$ and $m_\ell = 1$, what is (are) the possible value(s) of ℓ?

Principal Shells and Subshells

All orbitals with the same value of n are in the same **principal electronic shell** or **principal level**, and all orbitals with the same n and ℓ values are in the same **subshell**, or **sublevel**.

Principal electronic shells are numbered according to the value of n. The first principal shell consists of orbitals with $n = 1$; the second principal shell of orbitals with $n = 2$; and so on. The value of n relates to the energy and most probable distance of an electron from the nucleus. The higher the value of n, the greater the electron energy and the farther, on average, the electron is from the nucleus. The principal quantum number, therefore, has a physical significance, as do the other quantum numbers. The quantum number ℓ determines the angular distribution, or *shape*, of an orbital and m_ℓ determines the *orientation* of the orbital.

The number of subshells in a principal electronic shell is the same as the number of allowed values of the orbital angular momentum quantum number, ℓ. In the first principal shell, with $n = 1$, the only allowed value of ℓ is 0, and there is a single subshell. The second principal shell $(n = 2)$, with the allowed ℓ values of 0 and 1, consists of two subshells; the third principal shell $(n = 3)$ has three subshells ($\ell = 0, 1$, and 2); and so on. Or, to put the matter in another way, because there are n possible values of the ℓ quantum number, that is, $0, 1, 2, \ldots (n - 1)$, the number of subshells in a principal shell is equal to the principal quantum number. As a result, there is one subshell in the principal shell with $n = 1$, two subshells in the principal shell with $n = 2$, and so on. The name given to a subshell, regardless of the principal shell in which it is found, depends on the value of the ℓ quantum number. The first four subshells are

s subshell	*p subshell*	*d subshell*	*f subshell*
$\ell = 0$	$\ell = 1$	$\ell = 2$	$\ell = 3$

The number of orbitals in a subshell is the same as the number of allowed values of m_ℓ for the particular value of ℓ. Recall that the allowed values of m_ℓ are $0, \pm1, \pm2, \ldots \pm\ell$, and thus the total number of orbitals in a subshell is $2\ell + 1$. The names of the orbitals are the same as the names of the subshells in which they appear.

s orbitals	*p* orbitals	*d* orbitals	*f* orbitals
$\ell = 0$	$\ell = 1$	$\ell = 2$	$\ell = 3$
$m_\ell = 0$	$m_\ell = 0, \pm 1$	$m_\ell = 0, \pm 1, \pm 2$	$m_\ell = 0, \pm 1, \pm 2, \pm 3$
one *s* orbital in an *s* subshell	three *p* orbitals in a *p* subshell	five *d* orbitals in a *d* subshell	seven *f* orbitals in an *f* subshell

To designate the particular principal shell in which a given subshell or orbital is found, we use a combination of a number and a letter. For example, the symbol $2p$ is used to designate both the p subshell of the second principal shell and any of the three p orbitals in that subshell.

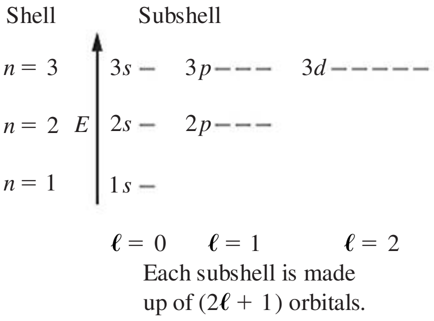
The energies of the orbitals for a hydrogen atom, in joules, are given by an equation with a familiar appearance.

$$E_n = -2.178 \times 10^{-18}\left(\frac{1}{n^2}\right)\text{ J}$$

▶ In Section 8-10 and in Chapter 24, we will see that orbital energies of multielectron atoms also depend on the quantum numbers ℓ and m_ℓ.

It is the same as equation (8.5), the formula derived by Bohr. Orbital energies for a hydrogen atom depend only on the principal quantum number n. This means that all the subshells within a principal electronic shell have the same energy, as do all the orbitals within a subshell. Orbitals at the same energy level are said to be **degenerate**. Figure 8-23 shows an energy-level diagram and the arrangement of shells and subshells for a hydrogen atom.

Some of the points discussed in the preceding paragraphs are illustrated in Example 8-11.



▶ FIGURE 8-23
Shells and subshells of a hydrogen atom
The hydrogen atom orbitals are organized into shells and subshells.

EXAMPLE 8-11 Relating Orbital Designations and Quantum Numbers

Write an orbital designation corresponding to the quantum numbers $n = 4, \ell = 2, m_\ell = 0$.

Analyze

To write orbital designations you need to recall the conventions associated with the quantum numbers n and ℓ. For the quantum number n we use only the number while for the quantum number ℓ we use the following letters $\ell = 0, s; \ell = 1, p; \ell = 2, d;$ and so on.

Solve

The magnetic quantum number, m_ℓ, is not reflected in the orbital designation. The type of orbital is determined by the ℓ quantum number. Because $\ell = 2$, the orbital is of the d type. Because $n = 4$, the orbital designation is $4d$.

Assess

This is another type of problem in which we need to have memorized the quantum number rules and their designations. This information will be important in the later chapters.

PRACTICE EXAMPLE A: Write an orbital designation corresponding to the quantum numbers $n = 3, \ell = 1$, and $m_\ell = 1$.

PRACTICE EXAMPLE B: Write all the combinations of quantum numbers that define hydrogen-atom orbitals with the same energy as the $3s$ orbital.

8-8 Interpreting and Representing the Orbitals of the Hydrogen Atom

Our major undertaking in this section will be to describe the three-dimensional probability density distributions obtained for the various orbitals in the hydrogen atom. Through the Born interpretation of wave functions (page 320), we will represent the probability densities of the orbitals of the hydrogen atom as surfaces that encompass most of the electron probability. We will see that the probability density for each type of orbital has its own distinctive shape, and like all waves, probability densities exhibit nodes and differing phase behavior. In studying this section, it is important for you to remember that, even though we will offer some additional quantitative information about orbitals, your primary concern should be to acquire a broad qualitative understanding. It is this qualitative understanding that you can apply in our later discussion of how orbitals enter into a description of chemical bonding.

Throughout this discussion, recall that orbitals are wave functions, mathematical solutions of the Schrödinger wave equation. The wave function itself has no physical significance. However, the square of the wave function, ψ^2, is a quantity that is related to probabilities. Probability density distributions based on ψ^2 are three-dimensional, and it is these three-dimensional regions that we mean when we refer to the shape of an orbital.

◀ In Chapter 11, we will discover important uses of the wave function, ψ, itself as a basis for discussing bonding between atoms.

The forms of the radial wave function $R(r)$ and the angular wave function $Y(\theta, \phi)$ for a one-electron, hydrogen-like atom are shown in Table 8.1. The first thing to note is that the angular part of the wave function for an *s* orbital,

TABLE 8.1 The Angular and Radial Wave Functions of a Hydrogen-Like Atom

Angular Part $Y(\theta, \phi)$	Radial Part $R_{n,\ell}(r)$
$Y(s) = \left(\frac{1}{4\pi}\right)^{1/2}$	$R(1s) = 2\left(\frac{Z}{a_0}\right)^{3/2} e^{-\sigma/2}$
	$R(2s) = \frac{1}{2\sqrt{2}}\left(\frac{Z}{a_0}\right)^{3/2}(2 - \sigma)e^{-\sigma/2}$
	$R(3s) = \frac{1}{9\sqrt{3}}\left(\frac{Z}{a_0}\right)^{3/2}(6 - 6\sigma + \sigma^2)e^{-\sigma/2}$
$Y(p_x) = \left(\frac{3}{4\pi}\right)^{1/2} \sin\theta\cos\phi$	$R(2p) = \frac{1}{2\sqrt{6}}\left(\frac{Z}{a_0}\right)^{3/2} \sigma e^{-\sigma/2}$
$Y(p_y) = \left(\frac{3}{4\pi}\right)^{1/2} \sin\theta\sin\phi$	$R(3p) = \frac{1}{9\sqrt{6}}\left(\frac{Z}{a_0}\right)^{3/2}(4 - \sigma)\sigma e^{-\sigma/2}$
$Y(p_z) = \left(\frac{3}{4\pi}\right)^{1/2} \cos\theta$	
$Y(d_{z^2}) = \left(\frac{5}{16\pi}\right)^{1/2}(3\cos^2\theta - 1)$	$R(3d) = \frac{1}{9\sqrt{30}}\left(\frac{Z}{a_0}\right)^{3/2} \sigma^2 e^{-\sigma/2}$
$Y(d_{x^2-y^2}) = \left(\frac{15}{16\pi}\right)^{1/2} \sin^2\theta\cos 2\phi$	
$Y(d_{xy}) = \left(\frac{15}{16\pi}\right)^{1/2} \sin^2\theta\sin 2\phi$	$\sigma = \frac{2Zr}{na_0}$
$Y(d_{xz}) = \left(\frac{15}{4\pi}\right)^{1/2} \sin\theta\cos\theta\cos\phi$	
$Y(d_{yz}) = \left(\frac{15}{4\pi}\right)^{1/2} \sin\theta\cos\theta\sin\phi$	

$\left(\frac{1}{4\pi}\right)^{1/2}$, is always the same, regardless of the principal quantum number. Next, note that the angular parts of the p and d orbitals are also independent of the quantum number n. Therefore all orbitals of a given type (s, p, d, f) have the same angular behavior. Also note that the equations in Table 8.1 are in a general form where the atomic number Z is included. This means that the equations apply to any one-electron atom, that is, to a hydrogen atom or a hydrogen-like ion. Finally, note that the term σ appearing throughout the table is equal to $2Zr/na_0$.

To obtain the wave function for a particular state, we simply multiply the radial part by the angular part. We will now illustrate this by looking at the three major types of orbitals.

s Orbitals

To obtain a complete wave function for the hydrogen 1s orbital, we use $Z = 1$ and $n = 1$, and combine the angular and radial wave functions where the red (radial) and blue (angular) colors indicate the origin of the two parts of the wave function.

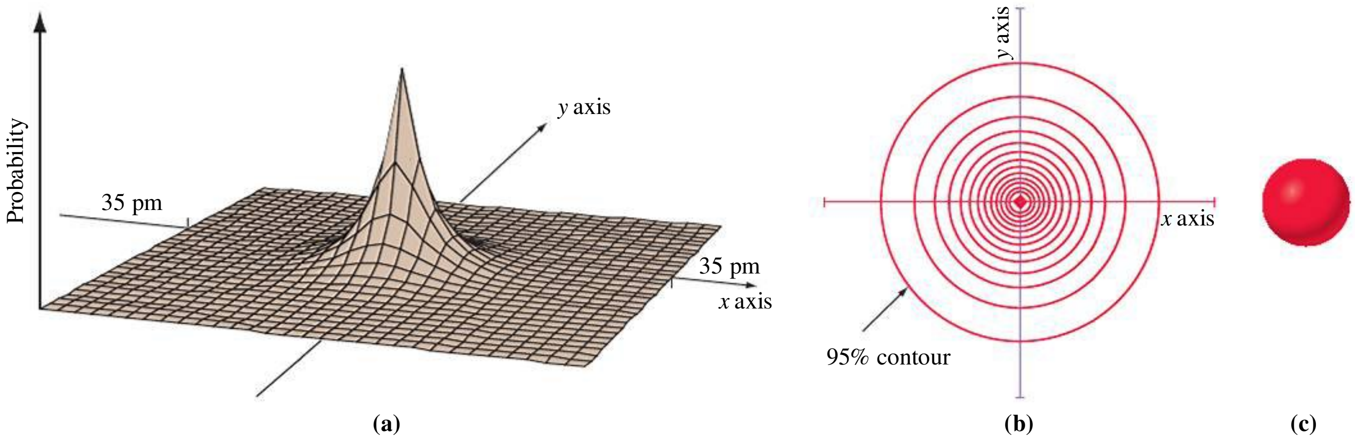
$$\psi(1s) = R(r) \times Y(\theta, \phi) = \frac{2e^{-r/a_0}}{a_0^{3/2}} \times \frac{1}{\sqrt{4\pi}} = \frac{e^{-r/a_0}}{\sqrt{(\pi a_0^3)}}$$

The term a_0 has the same significance as in the Bohr theory; it is the first Bohr radius—53 pm. By squaring $\psi(1s)$ we obtain an expression for the probability density of finding a 1s electron at a distance r from the nucleus in a hydrogen atom.

▶ $\psi^2(1s)$ is the probability density for a 1s electron at *one* point a distance r from the nucleus. Equally important is the probability density distribution, which gives the total probability for *all* points at a distance r from the nucleus. In Section 8-10 we will see that this distribution is given by $4\pi r^2\psi^2$.

$$\psi^2(1s) = \frac{1}{\pi}\left(\frac{1}{a_0}\right)^3 e^{-2r/a_0} \qquad \textbf{(8.18)}$$

How can we represent ψ^2 in expression (8.18)? One way is to pass a plane through the nucleus (for example, the xy plane) and plot a graph of electron probability densities (ψ^2) as perpendicular heights above the many points in the plane at which the electron might be found. The resultant graph, seen in Figure 8-24(a), looks like a symmetrical, cone-shaped "hill" (think of a volcano)



▲ FIGURE 8-24
Three representations of the electron probability density for the 1*s* orbital
(a) In this diagram the probability density is represented by the height above the *xy* plane (the *xy* plane is an arbitrary choice, any plane could have been chosen). **(b)** A contour map of the 1*s* orbital probability density in the *xy* plane, pointing out the 95% contour. **(c)** A reduced scale 3D representation of the 95% contour of a 1*s* orbital.

of electron probability densities with its peak directly above the nucleus. As in topographical maps of Earth's surface, we can project the three-dimensional surface onto a two-dimensional contour map. The contour map of the "hill" of electron probability densities is shown in Figure 8-24(b). The circular contour lines join points of equal electron probability density. The contours close to the nucleus join points of high probability of finding the electron, those farther away correspond to a lower probability. A simpler way to display the electron probability is to select just one large contour that together with all the contours within it, encompasses an area of high probability of finding the electron. The contour usually chosen is the one outlining an area in which the chance of finding the electron is 95%. The 95% contour just described is for a plane passing through the nucleus, but an electron in a 1*s* orbital moves in three-dimensional space. The complete 95% probability surface is a sphere, as seen in Figure 8-24(c).

Now let's look at the wave function of the 2*s* orbital.

$$\psi(2s) = R(r) \times Y(\theta,\phi) = \frac{1}{2\sqrt{2}}\,\frac{1}{a_0^{3/2}}\left(2 - \frac{r}{a_0}\right)e^{-r/2a_0} \times \frac{1}{\sqrt{4\pi}} = \frac{1}{4}\left(\frac{1}{2\pi a_0^3}\right)^{1/2}\left(2 - \frac{r}{a_0}\right)e^{-r/2a_0}$$

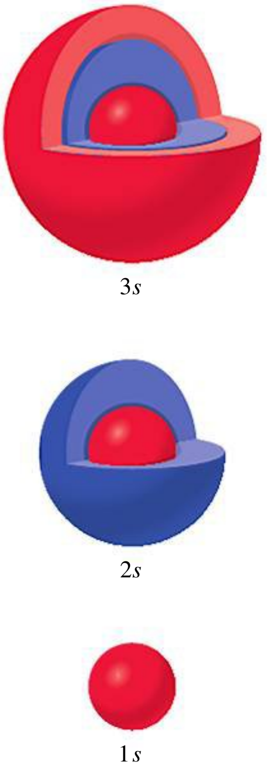
The electron probability density for the 2*s* orbital is given by

$$\psi^2(2s) = \frac{1}{8\pi}\left(\frac{1}{a_0}\right)^3\left(2 - \frac{r}{a_0}\right)^2 e^{-r/a_0} \qquad \textbf{(8.19)}$$

which, when compared to expression (8.18) for the 1*s* orbital, shows that the 2*s* electron tends to stay farther from the nucleus than the 1*s* electron, because the exponential has changed from $-2r/a_0$ for the 1*s* (equation 8.18) to $-r/a_0$ for the 2*s* orbital (equation 8.19). The exponential of the 2*s* orbital decays more slowly than that of the 1*s*.

The factor $\left(2 - \frac{r}{a_0}\right)$ in the 2*s* wave function controls the sign of the function. For small values of r, r/a_0 is smaller than two and the wave function is positive, but for large values of r, r/a_0 is larger than two and the wave function is negative. At $r = 2a_0$, the pre-exponential factor is zero and the wave function is said to have a *radial node*. The wave function changes phase (sign) at this radial node.

The fact that the electron probability density of the 2*s* orbital extends farther from the nucleus than that of the 1*s* orbital, together with the presence of the node, means that the 95% electron probability density sphere of a 2*s* orbital is bigger than that of a 1*s* orbital and contains a sphere of zero probability due to the radial node. These features are illustrated in Figure 8-25, which compares the 1*s*, 2*s*, and 3*s* orbitals. Note that the 3*s* orbital exhibits two radial nodes and is larger than both the 1*s* and 2*s* orbitals. The number of nodes increases as the energy is increased—a characteristic of high-energy standing waves. To highlight the change in phase of an orbital in progressing outward from the nucleus, we have adopted the modern usage of different colors to represent a change in phase. Thus in Figure 8-25 the 1*s* orbital is a single red color throughout, whereas the 2*s* orbital starts out red and then switches to blue; and finally, the 3*s* starts out red, changes to blue and then back to red, reflecting the presence of two radial nodes. We now turn our attention to the *p* orbitals.



▲ FIGURE 8-25
Three-dimensional representations of the 95% electron probability density for the 1*s*, 2*s*, and 3*s* orbitals
The first three s orbitals of the hydrogen atom. Note the increasing size of the 95% probability density contour in proceeding from 1*s* to 2*s* and on to 3*s*.

p Orbitals

The radial part of $\psi(2p)$ for a hydrogen atom is

$$R(2p) = \frac{1}{2\sqrt{6}}\left(\frac{1}{a_0}\right)^{3/2}\frac{r}{a_0}e^{-r/2a_0}$$

Thus, the $2p$ orbital has no radial nodes at finite values of r. In contrast to the s orbitals, which are nonzero at $r = 0$, the p orbitals vanish at $r = 0$. This difference will have an important consequence when we consider multielectron atoms.

In contrast to the angular function of the $2s$ orbital, the angular part of the $2p$ orbital is not a constant, but a function of θ and ϕ. This means that the electron probability density distribution of a p orbital is not spherically symmetric; that is, it does not have a spherical shape. We see this most easily in Table 8.1 in the functional form of the angular part of the $2p_z$ wave function; it is proportional to $\cos\theta$. Thus the $2p_z$ wave function has an angular maximum along the positive z axis, for there $\theta = 0$ and $\cos 0 = +1$. Along the negative z axis, the p_z wave function has its most negative value, for there $\theta = \pi$ and $\cos\pi = -1$. That the angular part has its maximum magnitude along the z axis is the reason for the designation p_z. Everywhere in the xy plane $\theta = \pi/2$ and $\cos\theta = 0$, so the xy plane is a node. Because this node arises in the angular function, it is called an *angular node*. A similar analysis of the p_x and p_y orbitals shows that they are similar to the p_z orbital, but with angular nodes in the yz and xz planes, respectively.

▶ The points at which a wave function changes sign are nodes. However, even though the $2p$ wave function becomes zero at $r = 0$ and $r = \infty$, these points are not true nodes because the function does not change sign at these points. These points are sometimes called *trivial nodes*.

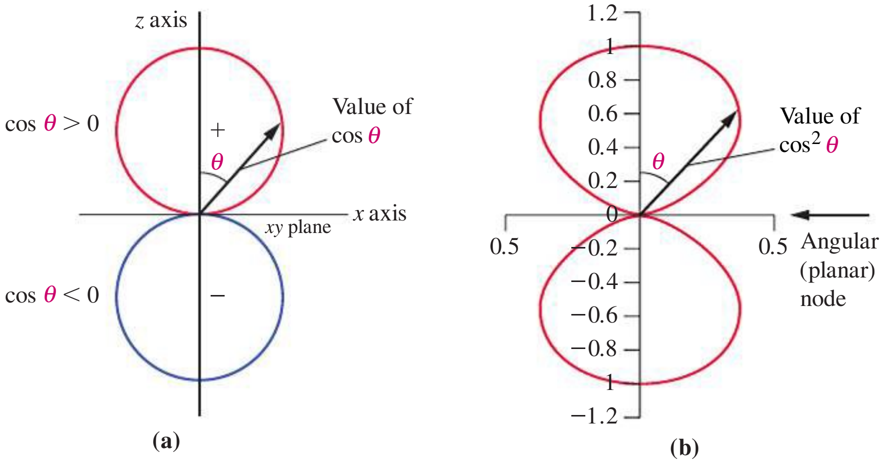
Figure 8-26 shows the two ways of representing the angular part of the p_z wave function. In Figure 8-26(a), the function $\cos\theta$ is plotted as a function of θ and results in two tangential circles. In Figure 8-26(b), the function $\cos^2\theta$, which is related to the angular electron probability density, is plotted as a function of θ, resulting in a double teardrop shape. Both these representations are used. What is important to note in part (a) of the figure is the phase of the plot of $\cos\theta$ and in (b), the lack of phase of $\cos^2\theta$, which is always positive. We shall see later in the text that the phase of the orbital is important in understanding chemical bonding.

The simultaneous display of both the radial and angular parts of $\psi^2(2p)$ is more difficult to achieve, but Figure 8-27 attempts to do this for the 95% probability surface of the p_z orbital. All three of the p orbitals are shown in Figure 8-28 and are seen to be directed along the three perpendicular axes of the Cartesian system. Again we have used different colors to represent the phase alternation in these orbitals. However, we must remember that these refer only to the phases of the original wave function, *not* to ψ^2.

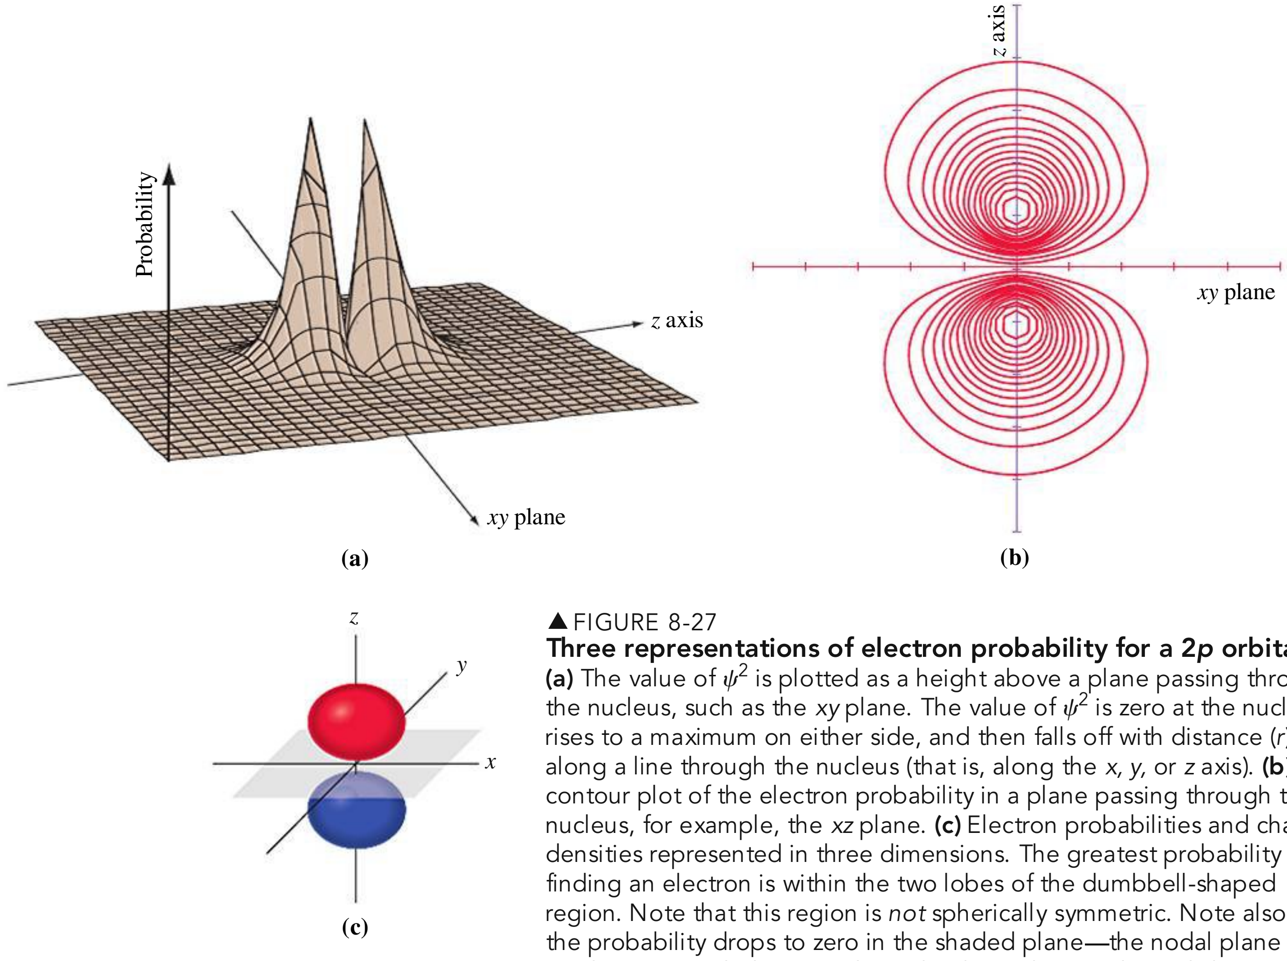
d Orbitals

The d orbitals occur for the first time when $n = 3$. The angular function in these cases possesses two angular (or planar) nodes. Let's illustrate this with the orbital that has an angular function proportional to

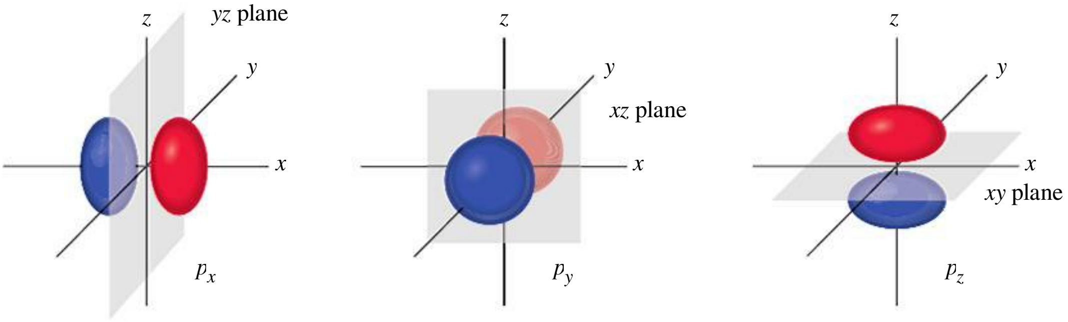
$$\sin^2\theta\cos 2\phi$$



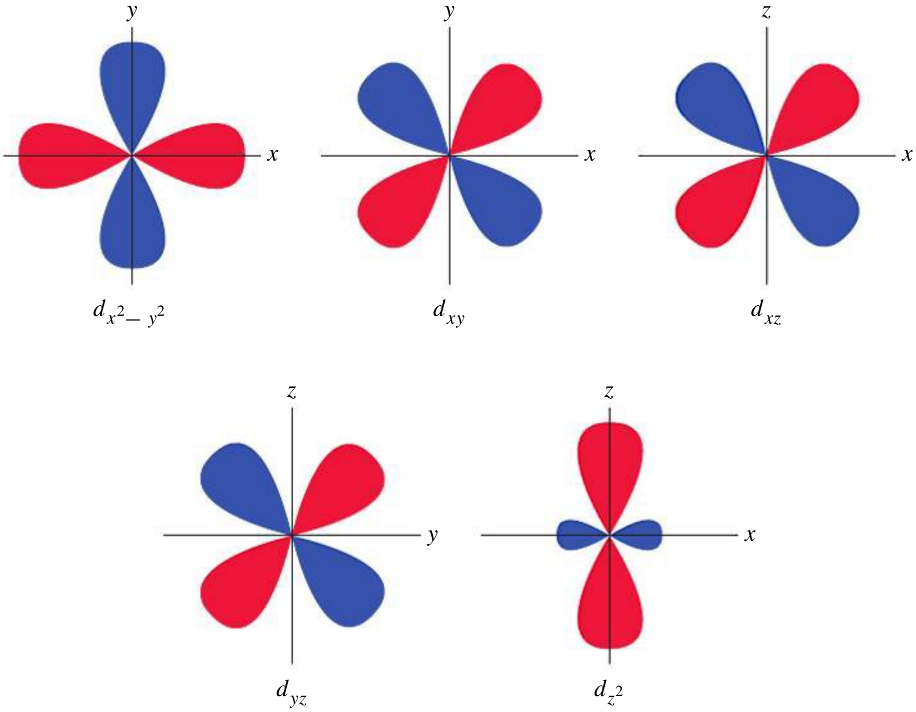
▶ FIGURE 8-26
Two representations of the *p* orbital angular function
(a) A plot of $\cos\theta$ in the zx plane, representing the angular part of the $2p_z$ wave function. Note the difference in the color of the function in the two lobes representing the phase of the angular wave function. **(b)** A plot of $\cos^2\theta$ in the zx plane, representing the square of the wave function and proportional to the angular probability density of finding the electron.



▲FIGURE 8-27
Three representations of electron probability for a 2*p* orbital
(a) The value of ψ^2 is plotted as a height above a plane passing through the nucleus, such as the *xy* plane. The value of ψ^2 is zero at the nucleus, rises to a maximum on either side, and then falls off with distance (*r*) along a line through the nucleus (that is, along the *x*, *y*, or *z* axis). **(b)** A contour plot of the electron probability in a plane passing through the nucleus, for example, the *xz* plane. **(c)** Electron probabilities and charge densities represented in three dimensions. The greatest probability of finding an electron is within the two lobes of the dumbbell-shaped region. Note that this region is *not* spherically symmetric. Note also that the probability drops to zero in the shaded plane—the nodal plane (the *xy* plane). As with the 2*s* and 3*s* orbitals, we have indicated changes of phase through different colors.



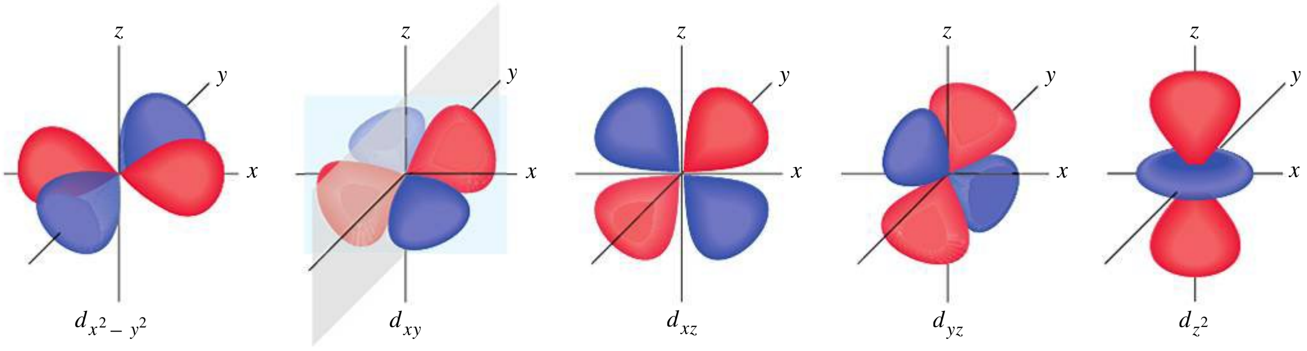
▲FIGURE 8-28
The three 2*p* orbitals
The *p* orbitals are usually represented as directed along the perpendicular *x*, *y*, and *z* axes, and the symbols p_x, p_y and p_z are often used. The p_z orbital has $m_\ell = 0$. The situation with p_x and p_y is more complex, however. Each of these orbitals has contributions from both $m_\ell = 1$ and $m_\ell = -1$. Our main concern is just to recognize that *p* orbitals occur in sets of three and can be represented in the orientation shown here. In higher-numbered shells, *p* orbitals have a somewhat different appearance, but we will use these general shapes for all *p* orbitals. The colors of the lobes signify the different phases of the original wave function.



▲ FIGURE 8-29
Cross sections of the five *d* orbitals
The two-dimensional cross sections of the angular functions of the five *d* orbitals in the planes indicated.

How should we visualize this function? We can proceed by setting $\theta = \pi/2$ and plotting the function $\cos 2\phi$. Study Figure 8-22 (page 324) and you will see that the angle $\theta = \pi/2$ corresponds to the *xy* plane, yielding the cross section in the upper left of Figure 8-29. The wave function exhibits positive and negative lobes, indicated by the red and blue lobes, respectively, along the *x* and *y* axes. This orbital, in common with all the other *d* orbitals, is a function of two of the three variables (x, y, and z). It is designated $d_{x^2-y^2}$. The other *d* orbitals, d_{xy}, d_{xz}, d_{yz}, and d_{z^2}, are also displayed in Figure 8-29. We observe that four of them have the same basic shape except for orientation with respect to the axes and that d_{z^2} has quite a different shape.

The 95% probability surfaces of the five *d* orbitals are shown in Figure 8-30. Two of the *d* orbitals ($d_{x^2-y^2}$ and d_{z^2}) are seen to be directed along the three



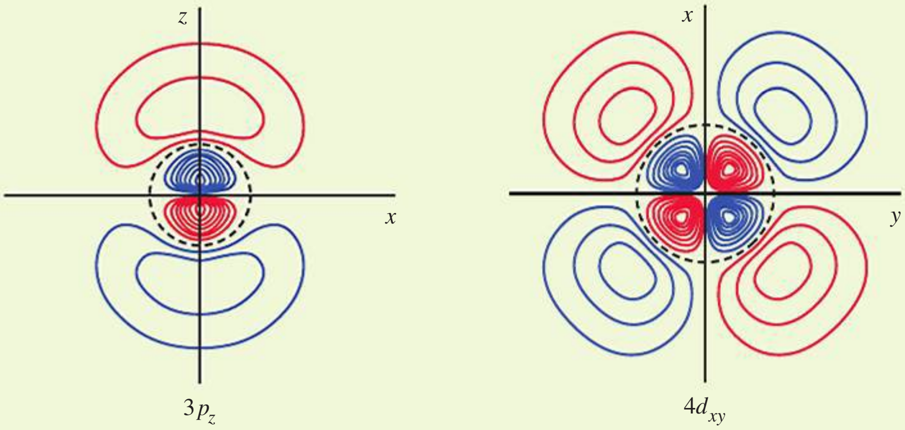
▲ FIGURE 8-30
Representations of the five *d* orbitals
The designations *xy*, *xz*, *yz*, and so on, are related to the values of the quantum number m_ℓ, but this is a detail that we will not pursue in the text. The number of nodal surfaces for an orbital is equal to the ℓ quantum number. For *d* orbitals, there are two such surfaces. The nodal planes for the d_{xy} orbital are shown here. (The nodal surfaces for the d_{z^2} orbital are actually cone-shaped.)

perpendicular axes of the Cartesian system, and the remaining three (d_{xy}, d_{xz}, d_{yz}) are seen to point between these Cartesian axes. Again, the relative phases of the lobes of the original wave function are indicated by the different colors. The *d* orbitals are important in understanding the chemistry of the transition elements, as we will see in Chapter 23.

8-6 ARE YOU WONDERING...

What does a $3p_z$ and a $4d_{xy}$ orbital look like?

When considering the shapes of the atomic orbitals with higher principal quantum number, we can draw on what we have discussed already and include the extra radial nodes that occur. For example, the $3p_z$ orbital has a total of two nodes (number of nodes $= n - 1$); one of these nodes is taken up with the angular node of the angular part of the $3p_z$ wave function, so that the radial part of the wave function will also have a node. Figure 8-31 shows a contour plot of the value of the $3p_z$ wave function in the *xz* plane in the manner of Figure 8-27(b). We notice that the $3p_z$ orbital has the same general shape as a $2p_z$ orbital due to the angular node, but the radial node has appeared as a circle (dashed in Figure 8-31). The appearance of the $3p_z$ orbital is that of a smaller *p* orbital inside a larger one. Similarly the $4d_{xy}$ orbital appears as a smaller d_{xy} inside a larger one. In Figure 8-31 the radial node is indicated by the dashed circle and the presence of the node is indicated by the alternation in color. This idea can be extended to enable us to sketch orbitals of increasing principal quantum number.



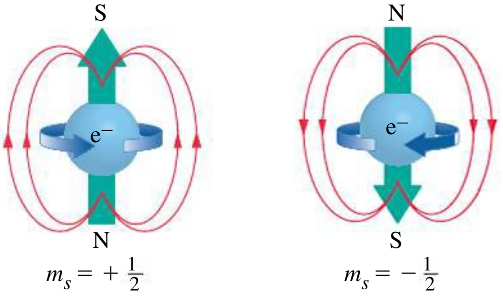
▲ FIGURE 8-31
Contour plots for $3p_z$ and the $4d_{xy}$ orbital
The relative phases in these orbitals are shown by the colors red and blue. The radial nodes are represented by the dashed circles.

8-7 CONCEPT ASSESSMENT

What type of orbital has three angular nodes and one radial node?

8-9 Electron Spin: A Fourth Quantum Number

Wave mechanics provides three quantum numbers with which we can develop a description of electron orbitals. However, in 1925, George Uhlenbeck and Samuel Goudsmit proposed that some unexplained features of

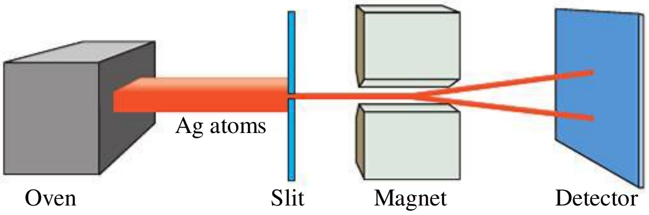


▲ FIGURE 8-32
Electron spin visualized
Two possibilities for electron spin are shown with their associated magnetic fields. Two electrons with opposing spins have opposing magnetic fields that cancel, leaving no net magnetic field for the pair.

the hydrogen spectrum could be understood by assuming that an electron acts as if it spins, much as Earth spins on its axis. As suggested by Figure 8-32, there are two possibilities for **electron spin**. Thus, these two possibilities require a fourth quantum number, the electron spin quantum number m_s. The electron spin quantum number may have a value of $+\frac{1}{2}$ (also denoted by the arrow ↑) or $-\frac{1}{2}$ (denoted by the arrow ↓); the value of m_s does not depend on any of the other three quantum numbers.

What is the evidence that the phenomenon of electron spin exists? An experiment by Otto Stern and Walter Gerlach in 1920, though designed for another purpose, seems to yield this proof (Fig. 8-33). Silver was vaporized in an oven, and a beam of silver atoms was passed through a nonuniform magnetic field, where the beam split in two. Here is a simplified explanation.

1. An electron, because of its spin, generates a magnetic field.
2. A pair of electrons with opposing spins has no net magnetic field.
3. In a silver atom, 23 electrons have a spin of one type and 24 of the opposite type. The direction of the net magnetic field produced depends only on the spin of the unpaired electron.
4. In a beam of a large number of silver atoms there is an equal chance that the unpaired electron will have a spin of $+\frac{1}{2}$ or $-\frac{1}{2}$. The magnetic field induced by the silver atoms interacts with the nonuniform field, and the beam of silver atoms splits into two beams.



▲ FIGURE 8-33
The Stern–Gerlach experiment
Ag atoms vaporized in the oven are collimated into a beam by the slit, and the beam is passed through a nonuniform magnetic field. The beam splits in two. The beam of atoms would not experience a force if the magnetic field were uniform. The field strength must be stronger in certain directions than in others.

Electronic Structure of the H Atom: Representing the Four Quantum Numbers

Now that we have described the four quantum numbers, we are in a position to bring them together into a description of the electronic structure of the hydrogen atom. The electron in a ground-state hydrogen atom is found at the lowest energy level. This corresponds to the principal quantum number $n = 1$, and because the first principal shell consists only of an *s* orbital, the orbital quantum number $\ell = 0$. The only possible value of the magnetic quantum number is $m_\ell = 0$. Either spin state is possible for the electron, and we do not know which it is unless we do an experiment like that of Uhlenbeck and Goudsmit's. Thus,

$$n = 1 \qquad \ell = 0 \qquad m_\ell = 0 \qquad m_s = +\frac{1}{2} \text{ or } -\frac{1}{2}$$

Chemists often say that the electron in the ground-state hydrogen atom is in the 1*s* orbital, or that it is a 1*s* electron, and they represent this by the notation

$$1s^1$$

where the superscript 1 indicates one electron in the 1*s* orbital. Either spin state is allowed, but we do not designate the spin state in this notation.

In the excited states of the hydrogen atom, the electron occupies orbitals with higher values of *n*. Thus, when excited to the level with $n = 2$, the electron can occupy either the 2*s* or one of the 2*p* orbitals; all have the same energy. Because the probability density extends farther from the nucleus in the 2*s* and 2*p* orbitals than in the 1*s* orbital, the excited-state atom is larger than is the ground-state atom. The excited states just described can be represented as

$$2s^1 \text{ or } 2p^1$$

In the remaining sections of the chapter this discussion will be extended to the electronic structures of atoms having more than one electron—*multielectron* atoms.

KEEP IN MIND

that orbitals are mathematical functions and not themselves physical regions in space. However, it is customary to refer to an electron that is described by a particular orbital as being "in the orbital."

EXAMPLE 8-12 Choosing an Appropriate Combination of the Four Quantum Numbers: *n*, *ℓ*, *m*

From the following sets of quantum numbers (n, ℓ, m_ℓ, m_s), identify the set that is correct, and state the orbital designation for those quantum numbers:

$$(2,1,0,0) \quad \left(2,0,1,\frac{1}{2}\right) \quad \left(2,2,0,\frac{1}{2}\right) \quad \left(2,-1,0,\frac{1}{2}\right) \quad \left(2,1,0,-\frac{1}{2}\right)$$

Analyze

We know that if $n = 2$, ℓ has two possible values: 0 or 1. The range of values for m_ℓ is given by equation (8.16), and $m_s = \pm\frac{1}{2}$. By using this information, we can judge which combination is correct.

Solve

(n, ℓ, m_ℓ, m_s)	**Comment**
$(2,1,0,0)$	The value of m_s is incorrect.
$\left(2,0,1,\frac{1}{2}\right)$	The value of m_ℓ is incorrect.
$\left(2,2,0,\frac{1}{2}\right)$	The value of ℓ is incorrect.
$\left(2,-1,0,\frac{1}{2}\right)$	The value of ℓ is incorrect.
$\left(2,1,0,-\frac{1}{2}\right)$	All the quantum numbers are correct.

(continued)

The correct combination of quantum numbers has $n = 2, \ell = 1, m_\ell = 0$, and $m_s = -\frac{1}{2}$, which corresponds to a $2p$ orbital.

Assess

The combination of quantum numbers identified above for an electron in a $2p$ orbital is one of six possible combinations. The other five combinations for an electron in a $2p$ orbital are $\left(2, 1, 0, \frac{1}{2}\right)$, $\left(2, 1, -1, -\frac{1}{2}\right)$, $\left(2, 1, -1, \frac{1}{2}\right)$, $\left(2, 1, 1, -\frac{1}{2}\right)$, and $\left(2, 1, 1, \frac{1}{2}\right)$.

PRACTICE EXAMPLE A: Determine which set of the following quantum numbers (n, ℓ, m_ℓ, m_s) is wrong and indicate why:

$$(3, 2, -2, 1) \quad \left(3, 1, -2, \frac{1}{2}\right) \quad \left(3, 0, 0, \frac{1}{2}\right) \quad \left(2, 3, 0, \frac{1}{2}\right) \quad \left(1, 0, 0, -\frac{1}{2}\right) \quad \left(2, -1, -1, \frac{1}{2}\right)$$

PRACTICE EXAMPLE B: Identify the error in each set of quantum numbers below:

$$(2, 1, 1, 0) \quad \left(1, 1, 0, \frac{1}{2}\right) \quad \left(3, -1, 1, -\frac{1}{2}\right) \quad \left(0, 0, 0, -\frac{1}{2}\right) \quad \left(2, 1, 2, \frac{1}{2}\right)$$

8-10 Multielectron Atoms

Schrödinger developed his wave equation for the hydrogen atom—an atom containing just one electron. For multielectron atoms, a new factor arises: mutual repulsion between electrons. The repulsion between the electrons means that the electrons in a multielectron atom tend to stay away from one another, and their motions become inextricably entangled. The approximate approach taken to solve this many-particle problem is to consider the electrons, one by one, in the environment established by the nucleus and the other electrons. When this is done, the electron orbitals obtained are of the same types as those obtained for the hydrogen atom; they are called *hydrogen-like* orbitals. Compared with the hydrogen atom, the angular parts of the orbitals of a multielectron atom are unchanged, but the radial parts are different.

We have seen that the solution of the Schrödinger equation for a hydrogen atom gives the energies of the orbitals and that all orbitals with the same principal quantum number n are degenerate—they have the same energy. In a hydrogen atom, the orbitals $2s$ and $2p$ are degenerate, as are $3s$, $3p$, and $3d$.

In multielectron atoms, the attractive force of the nucleus for a given electron increases as the nuclear charge increases. As a result, we find that orbital energies become lower (more negative) with increasing atomic number of the atom. Also, orbital energies in multielectron atoms depend on the type of orbital; the orbitals with different values of ℓ within a principal shell are not degenerate.

KEEP IN MIND

that orbital-wave functions extend farther out from the nucleus as n increases. Thus, an electron in a $3s$ or $3p$ orbital has a higher probability of being farther from the nucleus than does an electron in a $1s$ orbital.

Penetration and Shielding

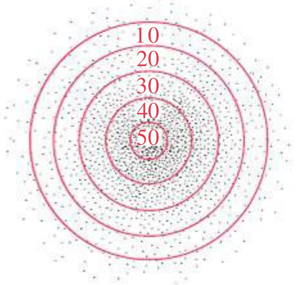
Think about the attractive force of the atomic nucleus for one particular electron some distance from the nucleus. Electrons in orbitals closer to the nucleus *screen* or *shield* the nucleus from electrons farther away. In effect, the screening electrons reduce the effectiveness of the nucleus in attracting the particular more-distant electron. They effectively reduce the nuclear charge.

The magnitude of the reduction of the nuclear charge depends on the types of orbitals the inner electrons are in and the type of orbital that the screened electron is in. We have seen that electrons in s orbitals have a high probability density at the nucleus, whereas p and d orbitals have zero probability densities at the nucleus. Thus, electrons in *s* orbitals are more effective at screening the nucleus from outer electrons than are electrons in *p* or *d* orbitals. This ability of electrons in *s* orbitals that allows them to get close to the nucleus is called *penetration*. An electron in an orbital with good penetration is better at screening than one with low penetration.

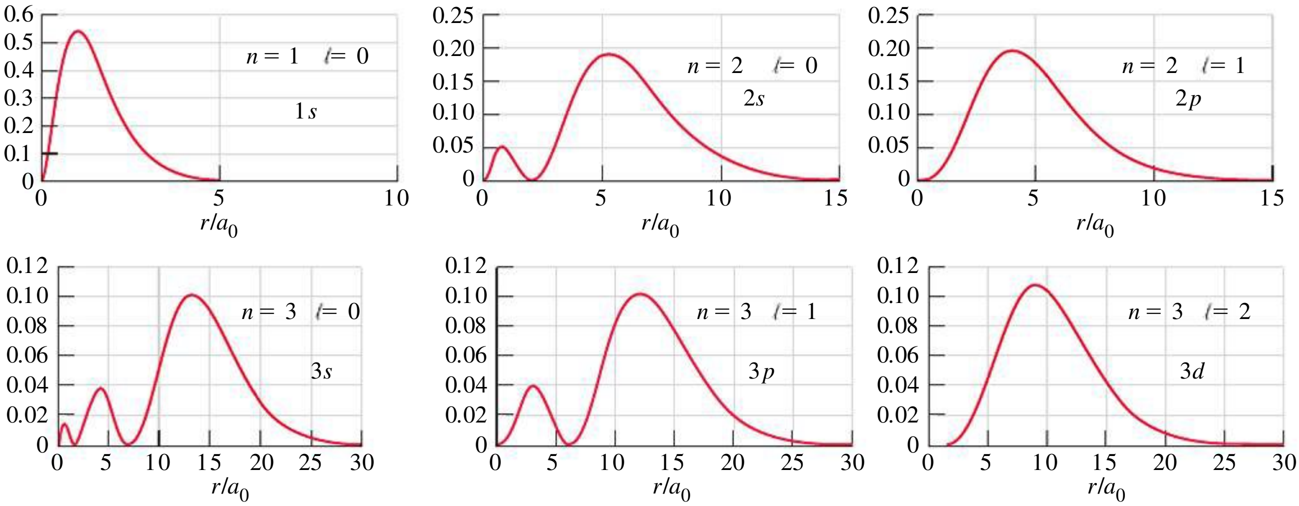
We must consider a different kind of probability distribution to describe the penetration to the nucleus by orbital electrons. Rather than considering the probability at a point, which we did to ascribe three-dimensional shapes to orbitals, we need to consider the probability of finding the electron anywhere in a spherical shell of radius r and an infinitesimal thickness. This type of probability is called a *radial probability distribution* and is found by multiplying the radial probability density, $R^2(r)$, by the factor $4\pi r^2$, the area of a sphere of radius r. Figure 8-34 offers a dartboard analogy that might help clarify the distinction between probability at a point and probability in a region of space.

The quantity $4\pi r^2 \times R^2(r)$ provides a different insight into the behavior of the electron. The radial probability distributions for some hydrogenic (hydrogen-like) orbitals are plotted in Figure 8-35. The radial probability density, $R^2(r)$, for a 1*s* orbital predicts that the maximum probability for a 1*s* electron is *at* the nucleus. However, because the volume of this region is vanishingly small $(r = 0)$, the radial probability distribution $[4\pi r^2 \times R^2(r)]$ is zero at the nucleus. The electron in a hydrogen atom is most likely to be found 53 pm from the nucleus; this is where the radial probability distribution reaches a maximum. This is the same radius as the first Bohr orbit. The boundary surface within which there is a 95% probability of finding an electron (see Figure 8-25, p. 329) is a much larger sphere, one with a radius of about 141 pm.

In comparing the radial probability curves for the 1*s*, 2*s*, and 3*s* orbitals, we find that a 1*s* electron has a greater probability of being close to the nucleus than a 2*s* electron does, which in turn has a greater probability than does a 3*s* electron. In comparing 2*s* and 2*p* orbitals, a 2*s* electron has a greater chance of being close to the nucleus than a 2*p* electron does. The 2*s* electron exhibits



▲ FIGURE 8-34
Dartboard analogy to a 1*s* orbital
Imagine that a single dart (electron) is thrown at a dartboard 1500 times. The board contains 95% of all the holes; it is analogous to the 1*s* orbital. Where is a thrown dart most likely to hit? The number of holes per unit area is greatest in the "50" region—that is, the 50 region has the greatest probability density. The most likely score is "30," however, because the most probable area hit is in the 30 ring and not the 50 ring, which is smaller than the 30 ring. The 30 *ring* on the dartboard is analogous to a spherical *shell* of 53 pm radius within the larger sphere representing the 1*s* orbital.



▲ FIGURE 8-35
Radial probability distributions
Graphs of the value of $4\pi r^2 R^2(r)$ as a function of r for the orbitals in the first three principal shells. Note that the smaller the orbital angular momentum quantum number, the more closely an electron approaches the nucleus. Thus, *s* orbital electrons penetrate more, and are less shielded from the nucleus, than electrons in other orbitals with the same value of *n*.

greater penetration than the 2*p* electron. Electrons having a high degree of penetration effectively "block the view" of an electron in an outer orbital "looking" for the nucleus.

The nuclear charge that an electron would experience if there were no intervening electrons is Z, the atomic number. The nuclear charge that an electron actually experiences is reduced by intervening electrons to a value of $\mathbf{Z_{eff}}$, called the **effective nuclear charge**. The less of the nuclear charge that an outer electron "sees" (that is, the smaller the value of Z_{eff}), the smaller is the attraction of the electron to the nucleus, and hence the *higher* is the energy of the orbital in which the electron is found.

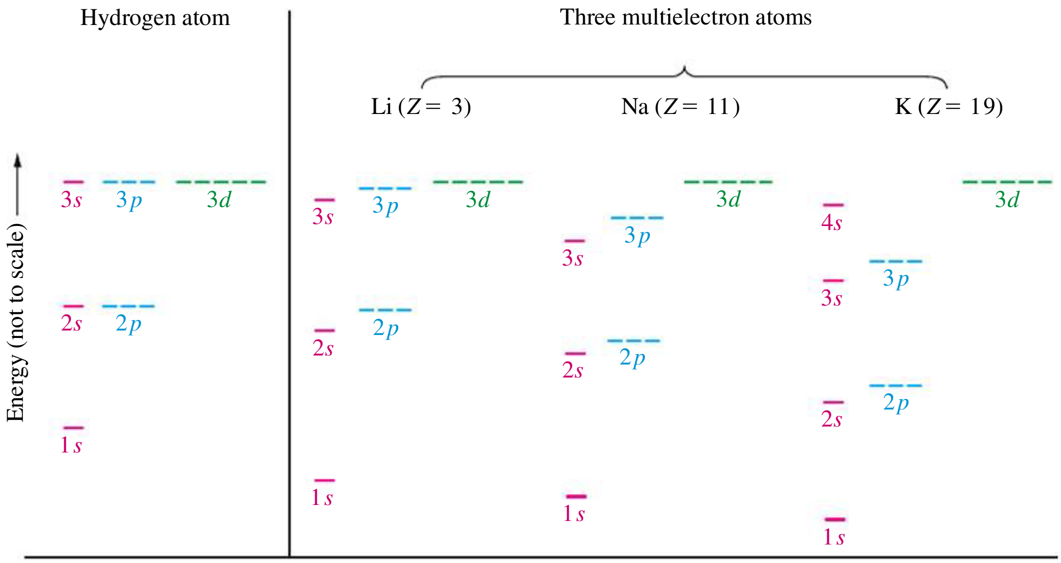
KEEP IN MIND

that, similar to the situation in equation (8.9), the energy of an orbital (E_n) is given by the proportionality

$$E_n \propto -\frac{Z_{eff}^2}{n^2}.$$

To summarize, compared with a *p* electron in the same principal shell, an *s* electron is more penetrating and not as well screened. The *s* electron experiences a higher Z_{eff}, is held more tightly, and is at a lower energy than a *p* electron. Similarly, the *p* electron is at a lower energy than a *d* electron in the same principal shell. Thus, the energy level of a principal shell is split into separate levels for its subshells. There is no further splitting of energies within a subshell, however, because all the orbitals in the subshell have the same radial characteristics and thereby experience the same effective nuclear charge, Z_{eff}. As a result, all three *p* orbitals of a principal shell have the same energy; all five *d* orbitals have the same energy; and so on.

In a few instances, the combined effect of the decreased spacing between successive energy levels at higher quantum numbers (because of the energy dependence on $1/n^2$) and the splitting of subshell energy levels (because of shielding and penetration) causes some energy levels to overlap. For example, because of the extra penetration of a 4*s* electron over that of a 3*d* electron, the 4*s* energy level is below the 3*d* level despite its higher principal quantum number *n* (Fig. 8-36). We will see some of the consequences of this energy-level splitting in the next two sections, where we consider the relationship between the electronic structures of atoms and their positions in the periodic table.



▲ FIGURE 8-36
Orbital energy-level diagram for the first three electronic shells
Energy levels are shown for a hydrogen atom (left) and three typical multielectron atoms (right). Each multielectron atom has its own energy-level diagram. Note that for the hydrogen atom, orbital energies within a principal shell—for example, 3*s*, 3*p*, 3*d*—are alike (degenerate), but in a multielectron atom they become rather widely separated. Another feature of the diagram is the steady decrease in all orbital energies with increasing atomic number. Finally, note that the 4*s* orbital is at a lower energy than 3*d*.

8-11 Electron Configurations

The **electron configuration** of an atom is a designation of how electrons are distributed among various orbitals in principal shells and subshells. In later chapters, we will find that many of the physical and chemical properties of elements can be correlated with electron configurations. In this section, we will see how the results of wave mechanics, expressed as a set of rules, can help us to write probable electron configurations for the elements.

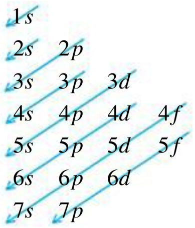
Rules for Assigning Electrons to Orbitals

1. **Electrons occupy orbitals in a way that minimizes the energy of the atom.** Figure 8-36 suggests the order in which electrons occupy the subshells in the principal electronic shells; first the 1*s*, then 2*s*, 2*p*, and so on. The exact order of filling of orbitals has been established by experiment, principally through spectroscopy and magnetic studies, and it is this order based on experiment that we must follow in assigning electron configurations to the elements. With only a few exceptions, the order in which orbitals fill is

$$1s, 2s, 2p, 3s, 3p, 4s, 3d, 4p, 5s, 4d, 5p, 6s, 4f, 5d, 6p, 7s, 5f, 6d, 7p \qquad \textbf{(8.20)}$$

Some students find the diagram pictured in Figure 8-37 a useful way to remember this order, but the best method of establishing the order of filling of orbitals is based on the periodic table, as we will see in Section 8-12.

◀ This order of filling corresponds roughly to the order of increasing orbital energy, but the overriding principle governing the order of filling of orbitals is that the energy of the atom as a whole be kept at a minimum.



▲ FIGURE 8-37
The order of filling of electronic subshells
Beginning with the top line, follow the arrows, and the order obtained is the same as in expression (8.20).

2. **No two electrons in an atom can have all four quantum numbers alike—the Pauli exclusion principle**. In 1926, Wolfgang Pauli explained complex features of emission spectra associated with atoms in magnetic fields by proposing that no two electrons in an atom can have all four quantum numbers alike. The first three quantum numbers, n, ℓ, and m_ℓ, determine a specific orbital. Two electrons may have these three quantum numbers alike; but if they do, they must have different values of m_s, the spin quantum number. Another way to state this result is that *only two electrons may occupy the same orbital, and these electrons must have opposing spins.*

   Because of this limit of two electrons per orbital, the capacity of a subshell for electrons can be obtained by doubling the number of orbitals in the subshell. Thus, the *s* subshell consists of *one* orbital with a capacity of *two* electrons; the *p* subshell consists of *three* orbitals with a total capacity of *six* electrons; and so on.

3. **When orbitals of identical energy (degenerate orbitals) are available, electrons initially occupy these orbitals singly**. In line with this rule, known as **Hund's rule**, an atom tends to have as many unpaired electrons as possible. This behavior can be rationalized by saying that electrons, because they all carry the same electric charge, try to get as far apart as possible. They do this by seeking out empty orbitals of similar energy in preference to pairing up with an electron in a half-filled orbital.

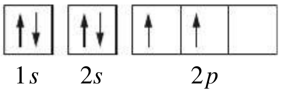
Representing Electron Configurations

Before we assign electron configurations to atoms of the different elements, we need to introduce methods of representing these configurations. The electron configuration of a carbon atom is shown in three different ways:

spdf notation (condensed): C $1s^22s^22p^2$

spdf notation (expanded): C $1s^22s^22p_x^12p_y^1$

orbital diagram: C



In each of these methods we assign six electrons because the atomic number of carbon is 6. Two of these electrons are in the 1*s* subshell, two in the 2*s*, and

▶ When listed in tables, as in Appendix D, electron configurations are usually written in the condensed *spdf* notation.

two in the 2*p*. The condensed ***spdf* notation** denotes only the total number of electrons in each subshell; it does not show how electrons are distributed among orbitals of equal energy. In the expanded ***spdf* notation,** Hund's rule is reflected in the assignment of electrons to the 2*p* subshell—two 2*p* orbitals are singly occupied and one remains empty. The **orbital diagram** breaks down each subshell into individual orbitals (drawn as boxes). This notation is similar to an energy-level diagram except that the direction of increasing energy is from left to right instead of vertically.

Electrons in orbitals are shown as arrows. An arrow pointing up corresponds to one type of spin $(+\frac{1}{2})$, and an arrow pointing down to the other $(-\frac{1}{2})$. Electrons in the same orbital with opposing (opposite) spins are said to be *paired* (↑↓). The electrons in the 1*s* and 2*s* orbitals of the carbon atom are paired. Electrons in different, singly occupied orbitals of the same subshell have the same, or *parallel*, spins (arrows pointing in the same direction). This is conveyed in the orbital diagram for carbon, where we write [↑][↑][ ] rather than [↑][↓][ ] for the 2*p* subshell. Both experiment and theory confirm that an electron configuration in which electrons in singly occupied orbitals have parallel spins is a better representation of the lowest energy state of an atom than any other electron configuration that we can write. The configuration represented by the orbital diagram [↑][↓][ ] is, in fact, an excited state of carbon; any orbital diagram with unpaired spins that are not parallel constitutes an excited state.

The most stable or the most energetically favorable configurations for isolated atoms, those discussed here, are called *ground-state electron configurations*. Later in the text we will briefly mention some electron configurations that are not the most stable. Atoms with such configurations are said to be in an *excited state*.

The Aufbau Process

To write electron configurations we will use the **aufbau process**. *Aufbau* is a German word that means "building up," and what we do is assign electron configurations to the elements in order of increasing atomic number. To proceed from one atom to the next, we add a proton and some neutrons to the nucleus and then describe the orbital into which the added electron goes.

$Z = 1$, H. The lowest energy state for the electron is the 1*s* orbital. The electron configuration is $1s^1$.

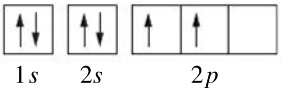
$Z = 2$, He. A second electron goes into the 1*s* orbital, and the two electrons have opposing spins, $1s^2$.

$Z = 3$, Li. The third electron cannot be accommodated in the 1*s* orbital (Pauli exclusion principle). It goes into the lowest energy orbital available, 2*s*. The electron configuration is $1s^22s^1$.

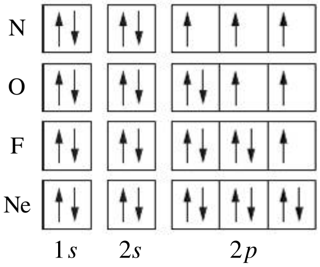
$Z = 4$, Be. The configuration is $1s^22s^2$.

$Z = 5$, B. Now the 2*p* subshell begins to fill: $1s^22s^22p^1$.

$Z = 6$, C. A second electron also goes into the 2*p* subshell, but into one of the remaining empty *p* orbitals (Hund's rule) with a spin parallel to the first 2*p* electron. (See figure to the left.)



$Z = 7$–10, N through Ne In this series of four elements, the filling of the subshell is completed. The number of unpaired electrons reaches a maximum (three) with nitrogen and then decreases to zero with neon.



$Z = 11$–18, Na through Ar. The filling of orbitals for this series of eight elements closely parallels the eight elements from Li through Ne, except that electrons go into $3s$ and $3p$ subshells. Each element has the $1s$, $2s$, and $2p$ subshells filled. Because the configuration $1s^2 2s^2 2p^6$ is that of neon, we will call this the neon core, represent it as [Ne], and concentrate on the electrons beyond the core. Electrons that are added to the electronic shell of highest principal quantum number (the outermost, or *valence shell*) are called **valence electrons**. The electron configuration of Na is written below in a form called a *noble-gas-core-abbreviated electron configuration*, consisting of [Ne] as the noble gas core and $3s^1$ as the configuration of the valence electron. For the other third-period elements, only the valence-shell electron configurations are shown.

Na	Mg	Al	Si	P	S	Cl	Ar
$[\mathrm{Ne}]3s^1$	$3s^2$	$3s^2 3p^1$	$3s^2 3p^2$	$3s^2 3p^3$	$3s^2 3p^4$	$3s^2 3p^5$	$3s^2 3p^6$

$Z = 19$ and 20, K and Ca. After argon, instead of $3d$, the next subshell to fill is $4s$. Using the symbol [Ar] to represent the noble gas core, $1s^2 2s^2 2p^6 3s^2 3p^6$, we get the electron configurations shown below for K and Ca.

$$\mathrm{K}: [\mathrm{Ar}]4s^1 \quad \text{and} \quad \mathrm{Ca}: [\mathrm{Ar}]4s^2$$

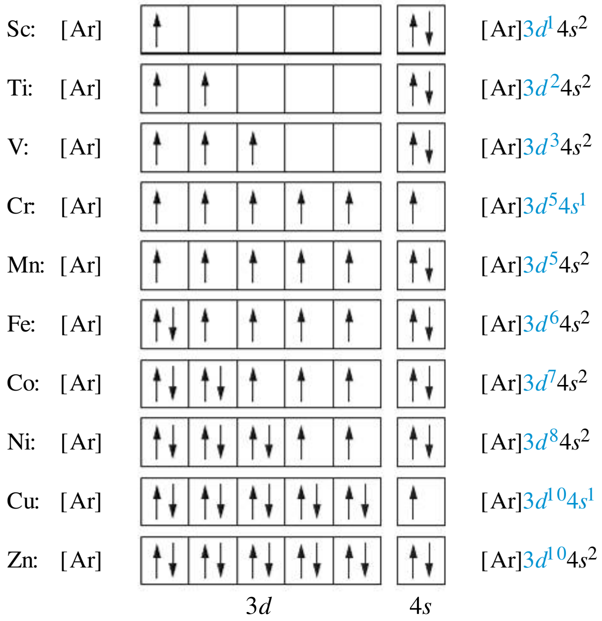
$Z = 21$–30, Sc through Zn. In this next series of elements, electrons fill the *d* orbitals of the third shell. The *d* subshell has a total capacity of ten electrons—ten elements are involved. There are two possible ways to write the electron configuration of scandium.

$$\text{(a) Sc}: [\mathrm{Ar}]3d^1 4s^2 \quad \text{or} \quad \text{(b) Sc}: [\mathrm{Ar}]4s^2 3d^1$$

Both methods are commonly used. Method (a) groups together all the subshells of a principal shell and places subshells of the highest principal quantum level last. Method (b) lists orbitals in the apparent order in which they fill. In this text, we will use method (a).

◀ Although method (b) conforms better to the order in which orbitals fill, method (a) better represents the order in which electrons are lost on ionization, as we will see in the next chapter.

The electron configurations of this series of ten elements are listed below in both the orbital diagram and the *spdf* notation.



Sc: [Ar] $[\mathrm{Ar}]3d^1 4s^2$
Ti: [Ar] $[\mathrm{Ar}]3d^2 4s^2$
V: [Ar] $[\mathrm{Ar}]3d^3 4s^2$
Cr: [Ar] $[\mathrm{Ar}]3d^5 4s^1$
Mn: [Ar] $[\mathrm{Ar}]3d^5 4s^2$
Fe: [Ar] $[\mathrm{Ar}]3d^6 4s^2$
Co: [Ar] $[\mathrm{Ar}]3d^7 4s^2$
Ni: [Ar] $[\mathrm{Ar}]3d^8 4s^2$
Cu: [Ar] $[\mathrm{Ar}]3d^{10} 4s^1$
Zn: [Ar] $[\mathrm{Ar}]3d^{10} 4s^2$
3d
4s

The *d* orbitals fill in a fairly regular fashion in this series, but there are two exceptions: chromium (Cr) and copper (Cu). These exceptions are usually explained in terms of a special stability for configurations in which a $3d$ subshell is half-filled with electrons, as with Cr $(3d^5)$, or completely filled, as with Cu $(3d^{10})$.

$Z = 31-36$, Ga through Kr. In this series of six elements, the $4p$ subshell is filled, ending with krypton.

$$\text{Kr: [Ar]}3d^{10}4s^24p^6$$

$Z = 37-54$, Rb to Xe. In this series of 18 elements, the subshells fill in the order $5s$, $4d$, and $5p$, ending with the configuration of xenon.

$$\text{Xe: [Kr]}4d^{10}5s^25p^6$$

$Z = 55-86$, Cs to Rn. In this series of 32 elements, with a few exceptions, the subshells fill in the order $6s$, $4f$, $5d$, $6p$. The configuration of radon is

$$\text{Rn: [Xe]}4f^{14}5d^{10}6s^26p^6$$

$Z = 87-?$, Fr to ? Francium starts a series of elements in which the subshells that fill are $7s$, $5f$, $6d$, and presumably $7p$, although atoms in which filling of the $7p$ subshell is expected have only recently been discovered and are not yet characterized.

Appendix D gives a complete listing of probable electron configurations.

8-7 ARE YOU WONDERING...

Why chromium and copper have "anomalous" electron configurations?

First we need to recognize that the balance between electron–electron repulsions, electron–nuclear attractions, and other electron–electron interactions, due to the fact that electron motions in a multielectron atom are correlated, determines the most stable electron configuration. Next, recall Hund's rule that the subshell electron configuration with the greatest number of unpaired electrons is the most stable. On page 340, this led us to the conclusion that the ground-state electron configuration of carbon is $1s^22s^22p^2$, with two unpaired electrons in the $2p$ subshell. Calculations on simple atoms and ions have shown that, although there is a larger electron–electron repulsion in the state with the unpaired electrons, this repulsion is more than offset by a larger electron–nucleus attraction because the electrons are closer to the nucleus in the configuration with unpaired electrons. Thus, configurations with unpaired electrons are favored.

In determining the ground-state electron configuration of Cr, we have to choose between $[\text{Ar}]3d^44s^2$ and $[\text{Ar}]3d^54s^1$, because the energies of the $3d$ and $4s$ orbitals are very similar. In this case, we can use Hund's rule to decide that the most stable electron configuration is that with the most unpaired electrons, that is, $[\text{Ar}]3d^54s^1$.

For Cu we have to choose between $[\text{Ar}]3d^94s^2$ and $[\text{Ar}]3d^{10}4s^1$, and there is no difference between the number of unpaired electrons—Hund's rule is no help here. So where does the extra stability for the configuration $[\text{Ar}]3d^{10}4s^1$ come from? A filled (or half-filled) subshell has a spherically symmetrical charge density that leads to a more stable electron configuration; and the greater the number of electrons in that subshell, the greater the stabilization. The $[\text{Ar}]3d^{10}4s^1$ electron configuration is more stable than $[\text{Ar}]3d^94s^2$ because of its filled $3d$ subshell. Thus nearly all the anomalous configurations contain either filled or half-filled subshells.

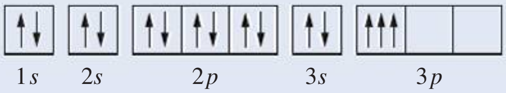
EXAMPLE 8-13 Recognizing Correct and Incorrect Ground State and Excited State Atomic Orbital Diagrams

Which of the following orbital diagrams is incorrect? Explain. Which of the correct diagrams corresponds to an excited state and which to the ground state of the neutral atom?

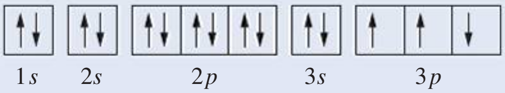
Analyze

When faced with a set of orbital diagrams, the best strategy is to investigate each one and apply Hund's rule and the Pauli exclusion principle, the former to decide on ground or excited states, and the latter for the correctness of the diagram.

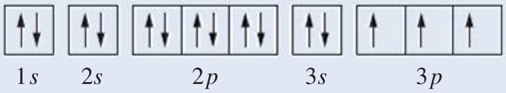
(a)



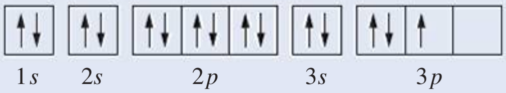
(b)



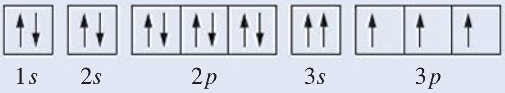
(c)



(d)



(e)



Solve

(a) By scanning diagram (a), we see that all the orbitals 1*s*, 2*s*, 2*p*, and 3*s* are filled with two electrons of opposite spin, conforming to the Pauli exclusion principle. However, the 3*p* orbital contains three electrons, which violates this principle.

(b) In diagram (b), the orbitals 1*s*, 2*s*, 2*p*, and 3*s* are filled with two electrons of opposite spin, which is correct. The 3*p* level contains three electrons in separate orbitals, conforming to Hund's rule, but two of them have opposite spin to the other; consequently, this is an excited state of the element.

(c) When we compare diagram (c) with diagram (b), we see that all the three electrons in the 3*p* subshell have the same spin, and so this is the ground state.

(d) When we compare diagram (d) with diagram (b), we see that of the three electrons in the 3*p* subshell, two are paired and one is not. Again, this is an excited state.

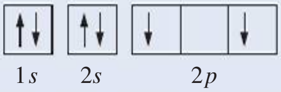
(e) By scanning diagram (e), we see that all the orbitals 1*s*, 2*s*, and 2*p* are filled with two electrons of opposite spin. However, the 3*p* orbital contains two electrons with the same spin, which violates the Pauli principle. This diagram is incorrect.

Assess

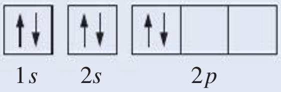
Orbital diagrams are a useful way to display electronic configurations, but we must take care to obey Hund's rule and the Pauli exclusion principle.

PRACTICE EXAMPLE A: Which two of the following orbital diagrams are equivalent?

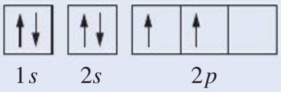
(a)



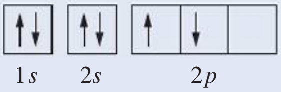
(b)



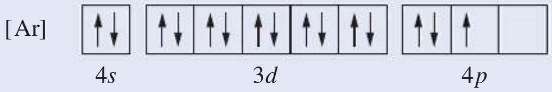
(c)



(d)



PRACTICE EXAMPLE B: Does the following orbital diagram for a neutral species correspond to the ground state or an excited state?



8-12 Electron Configurations and the Periodic Table

We have just described the aufbau process of making probable assignments of electrons to the orbitals in atoms. Although electron configurations may seem rather abstract, they actually lead us to a better understanding of the periodic table. Around 1920, Niels Bohr began to promote the connection between the periodic table and quantum theory. The chief link, he pointed out, is in electron configurations. *Elements in the same group of the table have similar electron configurations.*

To construct Table 8.2, we have taken three groups of elements from the periodic table and written their electron configurations. The similarity in electron configuration within each group is readily apparent. If the shell of the highest principal quantum number—the outermost, or valence, shell—is labeled n, then

- The group 1 atoms (alkali metals) have *one* outer-shell (valence) electron in an *s* orbital, that is, ns^1.
- The group 17 atoms (halogens) have *seven* outer-shell (valence) electrons, in the configuration ns^2np^5.
- The group 18 atoms (noble gases)—with the exception of helium, which has only two electrons—have outermost shells with *eight* electrons, in the configuration ns^2np^6.

▶ Hydrogen is found in group 1 because of its electron configuration, $1s^1$. However, it is not an alkali metal.

Although it is not correct in all details, Figure 8-38 relates the aufbau process to the periodic table by dividing the table into the following four blocks of elements according to the subshells being filled:

- ***s* block.** The *s* orbital of highest principal quantum number (n) fills. The *s* block consists of groups 1 and 2 (plus He in group 18).
- ***p* block.** The *p* orbitals of highest quantum number (n) fill. The *p* block consists of groups 13, 14, 15, 16, 17, and 18 (except He).
- ***d* block.** The *d* orbitals of the electronic shell $n - 1$ (the next to outermost) fill. The *d* block includes groups 3, 4, 5, 6, 7, 8, 9, 10, 11, and 12.
- ***f* block.** The *f* orbitals of the electronic shell $n - 2$ fill. The *f* block elements are the lanthanides and the actinides.

TABLE 8.2 Electron Configurations of Some Groups of Elements

Group	Element	Configuration
1	H	$1s^1$

▲ FIGURE 8-38

Electron configurations and the periodic table

To use this figure as a guide to the aufbau process, locate the position of an element in the table. Subshells listed ahead of this position are filled. For example, germanium ($Z = 32$) is located in group 14 of the blue $4p$ row. The filled subshells are $1s^2$, $2s^2$, $2p^6$, $3s^2$, $3p^6$, $4s^2$, and $3d^{10}$. At ($Z = 32$), a second electron has entered the $4p$ subshell. The electron configuration of Ge is $[\mathrm{Ar}]3d^{10}4s^24p^2$. Exceptions to the orderly filling of subshells suggested here are found among a few of the d-block and some of the f-block elements.

Another point to notice from Table 8.2 is that the electron configuration consists of a noble-gas core corresponding to the noble gas from the previous period plus the additional electrons required to satisfy the atomic number. Recognizing this and dividing the periodic table into blocks can simplify the task of assigning electron configurations. For example, strontium is in group 2, the second s-block group, so that its valence-shell configuration is $5s^2$ since it is in the fifth period. The remaining electrons are in the krypton core configuration (the noble gas in the previous period); thus the electron configuration of Sr is

$$\mathrm{Sr}: [\mathrm{Kr}]5s^2$$

For the p-block elements in groups 13 to 18, the number of valence electrons is from 1 to 6. For example, aluminum is in period 3 and group 13, its valence-shell electron configuration is $3s^23p^1$. We use $n = 3$ since Al is in the third period and we have to accommodate three electrons after the neon core, which contains 10 electrons. Thus the electron configuration of Al is

$$\mathrm{Al}: [\mathrm{Ne}]3s^23p^1$$

Gallium is also in group 13, but in period 4. Its valence-shell electron configuration is $4s^2 4p^1$. To write the electron configuration of Ga, we can start with the electron configuration of the noble gas that closes the third period, argon, and we add to it the subshells that fill in the fourth period: $4s$, $3d$, and $4p$. The $3d$ subshell must fill with 10 electrons before the $4p$ subshell begins to fill. Consequently, the electron configuration of gallium must be

$$\text{Ga: [Ar]}3d^{10}4s^2 4p^1$$

Thallium is in group 13 and period 6. Its valence-shell electron configuration is $6s^2 6p^1$. Again, we indicate the electron configuration of the noble gas that closes the fifth period as a core, and add the subshells that fill in the sixth period: $6s$, $4f$, $5d$, and $6p$.

$$\text{Tl: [Xe]}4f^{14}5d^{10}6s^2 6p^1$$

The elements in group 13 have the common valence configuration ns^2np^1, again illustrating the repeating pattern of valence electron configurations down a group, which is the basis of the similar chemical properties of the elements within a group of the periodic table.

The transition elements correspond to the *d* block, and their electron configurations are established in a similar manner. To write the electron configuration of a transition element, start with the electron configuration of the noble gas that closes the prior period and add the subshells that fill in the period of the transition element being considered. The *s* subshell fills immediately after the preceding noble gas; most transition metal atoms have two electrons in the *s* subshell of the valence shell, but some have only one. Thus, vanadium $(Z = 23)$, which has two valence electrons in the $4s$ subshell and core electrons in the configuration of the noble gas argon, must have *three* $3d$ electrons $(2 + 18 + 3 = 23)$.

$$\text{V: [Ar]}3d^3 4s^2$$

▶ The electron configurations for the *lower d- and fblock* elements contain many exceptions that need not be memorized. Few people know all of them. Anyone needing any of these configurations can look them up when needed in tables, such as in Appendix D.

Chromium $(Z = 24)$, as we have seen before, has only one valence electron in the $4s$ subshell and core electrons in the argon configuration. Consequently it must have *five* $3d$ electrons $(1 + 18 + 5 = 24)$.

$$\text{Cr: [Ar]}3d^5 4s^1$$

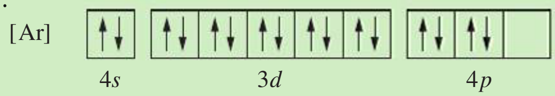
Copper $(Z = 29)$ also has only one valence electron in the $4s$ subshell in addition to its argon core, so the copper atom must have *ten* $3d$ electrons $(1 + 18 + 10 = 29)$.

$$\text{Cu: [Ar]}3d^{10}4s^1$$

Chromium and copper are two exceptions to the straightforward filling of atomic subshells in the first *d*-block row. An examination of the electron configurations of the heavier elements (Appendix D) will reveal that there are other special cases that are not easily explained—for example, gadolinium has the configuration $[\text{Xe}]4f^7 6d^1 6s^2$. Examples 8-14 through 8-16 provide several more illustrations of the assignment of electron configurations using the ideas presented here.

8-8 CONCEPT ASSESSMENT

The following orbital diagram represents an excited state of an atom. Identify the atom and give the orbital diagram corresponding to its ground state orbital diagram.



EXAMPLE 8-14 Using *spdf* Notation for an Electron Configuration

(a) Identify the element having the electron configuration

$$1s^22s^22p^63s^23p^5$$

(b) Write the electron configuration of arsenic.

Analyze

The total number of electrons in a neutral atomic species is equal to the atomic number of the element. All electrons must be accounted for in an electron configuration.

Solve

(a) Add the superscript numerals $(2 + 2 + 6 + 2 + 5)$ to obtain the atomic number 17. The element with this atomic number is chlorine.

(b) Arsenic $(Z = 33)$ is in period 4 and group 15. Its valence-shell electron configuration is $4s^24p^3$. The noble gas that closes the third period is Ar $(Z = 18)$, and the subshells that fill in the fourth period are $4s$, $3d$, and $4p$, in that order. Note that we account for 33 electrons in the configuration

$$\text{As: [Ar]}3d^{10}4s^24p^3$$

Assess

As long as we count the number of electrons accurately and know the order of the orbitals, we should be able to interpret or write the correct electronic configuration.

PRACTICE EXAMPLE A: Identify the element having the electron configuration $1s^22s^22p^63s^23p^63d^24s^2$.

PRACTICE EXAMPLE B: Use *spdf* notation to show the electron configuration of iodine. How many electrons does the I atom have in its $3d$ subshell? How many unpaired electrons are there in an I atom?

EXAMPLE 8-15 Representing Electron Configurations

Write **(a)** the electron configuration of mercury, and **(b)** an orbital diagram for the electron configuration of tin.

Analyze

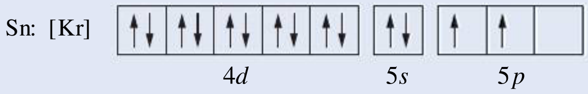
To write the electronic configuration, we locate the element on the periodic table and then ascertain which subshells are filled. We must be careful, with high-atomic-number elements, to take into account the lanthanide and actinide elements.

Solve

(a) Mercury, in period 6 and group 12, is the transition element at the end of the third transition series, in which the $5d$ subshell fills $(5d^{10})$. The noble gas that closes period 5 is xenon, and the lanthanide series intervenes between xenon and mercury, in which the $4f$ subshell fills $(4f^{14})$. When we put all these facts together, we conclude that the electron configuration of mercury is

$$[\text{Xe}]4f^{14}5d^{10}6s^2$$

(b) Tin is in period 5 and group 14. Its valence-shell electron configuration is $5s^25p^2$. The noble gas that closes the fourth period is Kr $(Z = 36)$, and the subshells that fill in the fifth period are $5s$, $4d$, and $5p$. Note that all subshells are filled in the orbital diagram except for $5p$. Two of the $5p$ orbitals are occupied by single electrons with parallel spins; one $5p$ orbital remains empty.



Assess

Using the periodic table helps when writing electronic configurations.

PRACTICE EXAMPLE A: Represent the electron configuration of iron with an orbital diagram.

PRACTICE EXAMPLE B: Represent the electron configuration of bismuth with an orbital diagram.

EXAMPLE 8-16 Relating Electron Configurations to the Periodic Table

Indicate the number of **(a)** valence electrons in an atom of bromine; **(b)** $5p$ electrons in an atom of tellurium; **(c)** unpaired electrons in an atom of indium; **(d)** $3d$ and $4d$ electrons in a silver atom.

Analyze

Determine the atomic number and the periodic table location of each element. Then, explain the significance of its location.

Solve

(a) Bromine $(Z = 35)$ is in group 17. There are seven outer-shell, or valence, electrons in all atoms in this group.

(b) Tellurium $(Z = 52)$ is in period 5 and group 16. There are six outer-shell electrons, two of them are s, and the other four are p. The valence-shell electron configuration of tellurium is $5s^2 5p^4$; the tellurium atom has four $5p$ electrons.

(c) Indium $(Z = 49)$ is in period 5 and group 13. The electron configuration of its inner shells is $[\mathrm{Kr}]4d^{10}$. All the electrons in this inner-shell configuration are paired. The valence-shell electron configuration is $5s^2 5p^1$. The two $5s$ electrons are paired, and the $5p$ electron is unpaired. The In atom has one unpaired electron.

(d) Ag $(Z = 47)$ is in period 5 and group 11. The noble gas that closes period 4 is krypton, and the $4d$ subshell fills $4(d^{10})$. There is one electron in the $5s$ orbital; thus the electron configuration of silver is

$$\text{Ag: } [\mathrm{Kr}]4d^{10}5s^1$$

There are ten $3d$ electrons and ten $4d$ electrons in a silver atom.

Assess

Again, the relationship between the periodic table and electronic configurations is evident.

PRACTICE EXAMPLE A: For an atom of Sn, indicate the number of **(a)** electronic shells that are either filled or partially filled; **(b)** $3p$ electrons; **(c)** $5d$ electrons; and **(d)** unpaired electrons.

PRACTICE EXAMPLE B: Indicate the number of **(a)** $3d$ electrons in Y atoms; **(b)** $4p$ electrons in Ge atoms; and **(c)** unpaired electrons in Au atoms.

MasteringCHEMISTRY **www.masteringchemistry.com**

Laser devices are in use everywhere—in compact disc players, bar-code scanners, laboratory instruments, and in cosmetic, dental, and surgical procedures. Lasers produce light with highly desirable properties by a process called stimulated emission. For a discussion of how lasers work, go to the Focus On feature for Chapter 8, Helium-Neon Lasers, on the MasteringChemistry site.

Summary

8-1 Electromagnetic Radiation—**Electromagnetic radiation** is a type of energy transmission in the form of a **wave**. The waves of electromagnetic radiation are characterized by an **amplitude**, the maximum height of wave crests and maximum depth of wave troughs, a **wavelength**, λ, the distance between wave crests and **frequency**, ν, which signifies how often the fluctuations occur. Frequency is measured in **hertz**, **Hz** (cycles per second). Wavelength and frequency are related by the equation (8.1): $c = \lambda\nu$, where c is the **speed of light**. The wave character of electromagnetic radiation means that the waves can be dispersed into individual components of different wavelengths, a **diffraction** pattern, by striking a closely grooved surface (Fig. 8-4).

8-2 Atomic Spectra—A rainbow results from the dispersion of all the wavelength components of visible light by a prism or raindrops; it is an example of a continuous spectrum (Fig. 8-7). The spectra produced by light emitted from excited atoms and ions are called **atomic spectra** or **line spectra**, because only certain frequencies are observed.

8-3 Quantum Theory—The study of electromagnetic radiation emitted from hot objects led to Planck's theory, which postulates that quantities of energy can have only certain discrete values, with the smallest unit of energy being that of a **quantum**. The energy of a quantum is given by equation (8.3): $E = h\nu$, where $\boldsymbol{h}$ is **Planck's constant**. Einstein's interpretation of the **photoelectric effect**—the ability of light to eject electrons when striking certain surfaces (Fig. 8-12)—led to a new interpretation of electromagnetic radiation: Light has a particle-like nature in addition to its wave-like properties. Light particles are called **photons**. The energy of a photon is related to the frequency of the radiation by $E_{\text{photon}} = h\nu$.

8-4 The Bohr Atom—The first attempt to explain atomic (line) spectra was made by Niels Bohr who postulated that an electron in a hydrogen atom exists in a circular orbit designated by a **quantum number**, n, that describes the energy of the electron in the orbit. The state of the electron with the lowest quantum number, $n = 1$, is called the **ground state**. An **excited state** of a hydrogen atom corresponds to those states with $n > 1$. The Bohr theory also provided a means for constructing an **energy-level diagram** (Fig. 8-14) so that emission spectra could be understood.

8-5 Two Ideas Leading to a New Quantum Mechanics—Louis de Broglie postulated a **wave–particle duality** in which particles of matter such as protons and electrons would at times display wave-like properties (equation 8.10). Because of an inherent uncertainty of the position and momentum of a wave-like particle, Heisenberg postulated that we cannot simultaneously know a subatomic particle's precise momentum and its position, a proposition referred to as the **Heisenberg uncertainty principle** (equation 8.11).

8-6 Wave Mechanics—The application of the concept of wave–particle duality requires that we view the electron in a system through a **wave function** that corresponds to a **standing wave** within the boundary of the system (Figs. 8-18 and 8-19). Application of these ideas to a particle in a one-dimensional box shows that at the lowest energy level the energy of the particle is nonzero that is, the system has a **zero-point energy**. The solution of the **Schrödinger equation** for the hydrogen atom provides wave functions called **orbitals**, which are the product of an **angular wave function**, $Y(\theta, \phi)$, and a **radial wave function**, $R(r)$.

8-7 Quantum Numbers and Electron Orbitals—The three quantum numbers arising from the Schrödinger wave equation are the *principal quantum number*, n, the *orbital angular momentum quantum number*, ℓ, and the *magnetic quantum number*, m_ℓ. All orbitals with the same value of n are in the same **principal electronic shell** (**principal level**), and all orbitals with the same values of n and ℓ are in the same **subshell** (**sublevel**). The orbitals with different values of ℓ (0, 1, 2, 3, and so on) are designated s, p, d, f (Fig. 8-23). Orbitals in the same subshell of a hydrogen-like species have the same energy and are said to be **degenerate**.

8-8 Interpreting and Representing the Orbitals of the Hydrogen Atom—Interpreting the solutions to the Schrödinger equation for the hydrogen atom leads to a description of the shapes of the electron probability distributions for electrons in the s, p, and d orbitals. The number of nodes $(n - 1)$ in an orbital increases as n increases. Nodes are where the wave function changes sign.

8-9 Electron Spin: A Fourth Quantum Number—Stern and Gerlach demonstrated that electrons possess a quality called **electron spin** (Figs. 8-32 and 8-33). The electron spin quantum number, m_s, takes the value $+\frac{1}{2}$ or $-\frac{1}{2}$.

8-10 Multielectron Atoms—In multielectron atoms, orbitals with different values of ℓ are not degenerate. The loss of degeneracy within a principal shell is a result of the different **effective nuclear charge**, $\mathbf{Z_{eff}}$, experienced by electrons in different subshells.

8-11 Electron Configurations—**Electron configuration** describes how the electrons are distributed among the various orbitals in principal shells and subshells of an atom. Electrons fill orbitals from the lowest energy to the highest (Fig. 8-37), ensuring that the energy of the atom is at a minimum. The **Pauli exclusion principle** states that a maximum of two electrons may occupy an orbital. **Hund's rule** says that when degenerate orbitals are available, electrons initially occupy these orbitals singly. Electron configurations are represented by either expanded or condensed ***spdf* notation** or an **orbital diagram** (page 339). The **aufbau process** is used to assign electron configurations to the elements of the periodic table. Electrons added to the shell of highest quantum number in the aufbau process are called **valence electrons**.

8-12 Electron Configurations and the Periodic Table—Elements in the same group of the periodic table have similar electron configurations. Groups 1 and 2 correspond to the ***s* block** with filled or partially filled valence-shell s orbitals. Groups 13 through 18 correspond to the ***p* block** with filled or partially filled valence-shell p orbitals. The ***d* block** corresponds to groups 3 through 12 as the $n - 1$ energy level is being filled—that is, having filled or partially filled d orbitals. In the ***f*-block** elements, also called the lanthanides and actinides, the $n - 2$ shell fills with electrons; that is, they have filled or partially filled f orbitals.

Integrative Example

Microwave ovens have become increasingly popular in kitchens around the world. They are also useful in the chemical laboratory, particularly in drying samples for chemical analysis. A typical microwave oven uses microwave radiation with a wavelength of 12.2 cm.

Are there any electronic transitions in the hydrogen atom that could *conceivably* produce microwave radiation of wavelength 12.2 cm? Estimate the principal quantum levels between which the transition occurs.

Analyze

Use the wavelength of microwaves to calculate the frequency of the radiation. Calculate the energy of the photon that has this frequency. Estimate where in the emission spectrum for a hydrogen atom such a photon emission might be found, by using equation (8.6).

Solve

1. Calculate the frequency of the microwave radiation. Microwaves are a form of electromagnetic radiation and thus travel at the speed of light, $2.998 \times 10^8\ \text{m s}^{-1}$. Convert the wavelength to meters, and then use the equation

$$\nu = c/\lambda$$

$$\nu = \frac{2.998 \times 10^8\ \text{m s}^{-1}}{12.2\ \text{cm} \times 1\ \text{m}/100\ \text{cm}} = 2.46 \times 10^9\ \text{Hz}$$

2. Calculate the energy associated with one photon of the microwave radiation. This is a direct application of Planck's equation.

$$E = h\nu = 6.626 \times 10^{-34}\ \text{J s} \times 2.46 \times 10^9\ \text{s}^{-1}$$
$$= 1.63 \times 10^{-24}\ \text{J}$$

3. Determine whether there are any electronic transitions in the hydrogen atom with an energy per photon of 1.63×10^{-24} J. Let the principal quantum number of the final state (n_f) be n, and that of the initial state (n_i) is then $n + 1$. Substitute these two values into equation (8.9).

$$E_{\text{photon}} = \Delta E = 2.179 \times 10^{-18}\ \text{J}\left(\frac{1}{(n+1)^2} - \frac{1}{n^2}\right)$$

Solving for n

$$E_{\text{photon}} = \Delta E = 2.179 \times 10^{-18}\ \text{J}\left(\frac{n^2 - (n+1)^2}{n^2(n+1)^2}\right)$$
$$= -2.179 \times 10^{-18}\ \text{J}\left(\frac{2n+1}{n^2(n+1)^2}\right)$$

4. The negative sign indicates that a photon is emitted and now can be ignored. Substitute the value for the energy of the photon and rearrange the equation

$$E_{\text{photon}} = 1.63 \times 10^{-24}\ \text{J} = 2.179 \times 10^{-18}\ \text{J}\left(\frac{2n+1}{n^2(n+1)^2}\right)$$
$$\frac{1.63 \times 10^{-24}\ \text{J}}{2.179 \times 10^{-18}\ \text{J}} = 7.48 \times 10^{-7} = \left(\frac{2n+1}{n^2(n+1)^2}\right)$$

5. Look at Figure 8-14, the *energy*-level diagram for the Bohr hydrogen atom. Energy differences between the low-lying levels are of the order 10^{-19} to 10^{-20} J. These are orders of magnitude (10^4 to 10^5 times) greater than the energy per photon of 1.63×10^{-24} J from part 2. Note, however, that the energy differences become progressively smaller for high-numbered orbits. As n approaches ∞, the energy differences approach zero, and some transitions between high-numbered orbits should correspond to microwave radiation. Thus we expect n to be large, so that to a good approximation we can neglect one with respect to n and write

$$7.48 \times 10^{-7} = \left(\frac{2n+1}{n^2(n+1)^2}\right) \simeq \left(\frac{2n}{n^2n^2}\right) \simeq \left(\frac{2}{n^3}\right)$$

Solving for n

$$n \simeq \left(\frac{2}{7.48 \times 10^{-7}}\right)^{1/3} \simeq 138.8$$

6. We can check this result by substituting this value of $n = 139$ into the exact expression

$$7.48 \times 10^{-7} = \frac{2n+1}{n^2(n+1)^2} = \frac{2(139)+1}{139^2(139+1)^2} = 7.37 \times 10^{-7}$$

The agreement is not very good, so let's try $n = 138$

$$7.48 \times 10^{-7} = \frac{2n+1}{n^2(n+1)^2} = \frac{2(138)+1}{138^2(138+1)^2} = 7.53 \times 10^{-7}$$

This provides closer agreement. The value of the principal quantum number is $n = 138$.

Assess

Using equation (8.6) we have shown that the emission of a photon for the deexcitation of an electron from $n = 139$ to $n = 138$ produces a wavelength for that photon in the microwave region. However, we might question whether the $n = 139$ state is still a bound state or whether the energy required to create this state causes ionization (see Exercise 106).

PRACTICE EXAMPLE A: Calculate the de Broglie wavelength of a helium atom at 25 °C and moving at the root-mean-square velocity. At what temperature would the average helium atom be moving fast enough to have a de Broglie wavelength comparable to that of the size of a typical atom, about 300 pm?

PRACTICE EXAMPLE B: By using a two-photon process (that is, two sequential excitations), a chemist is able to excite the electron in a hydrogen atom to the 5*d* level. Not all excitations are possible; they are governed by a selection rule. The selection rule states that the allowed excitations must have $\Delta\ell = +1$ or -1 and Δn can have any value. Use this selection rule to identify the possible intermediate levels (more than one are possible) involved, and calculate the frequencies of the two photons involved in each process. Identify the transitions allowed when a sample of hydrogen atoms excited to the 5*d* level exhibits an emission spectrum. When a sample of gaseous sodium atoms is similarly excited to the 5*d* level, what would be the difference in the emission spectrum observed?

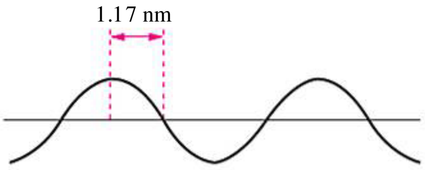
Exercises

Electromagnetic Radiation

1. A hypothetical electromagnetic wave is pictured here. What is the wavelength of this radiation?



2. For the electromagnetic wave described in Exercise 1, what are **(a)** the frequency, in hertz, and **(b)** the energy, in joules per photon?

3. The magnesium spectrum has a line at 266.8 nm. Which of these statements about this radiation is (are) correct? Explain.
   (a) It has a higher frequency than radiation with wavelength 402 nm.
   (b) It is visible to the eye.
   (c) It has a greater speed in a vacuum than does red light of wavelength 652 nm.
   (d) Its wavelength is longer than that of X-rays.

4. The most intense line in the cerium spectrum is at 418.7 nm.
   (a) Determine the frequency of the radiation producing this line.
   (b) In what part of the electromagnetic spectrum does this line occur?
   (c) Is it visible to the eye? If so, what color is it? If not, is this line at higher or lower energy than visible light?

5. *Without doing detailed calculations,* determine which of the following wavelengths represents light of the highest frequency: **(a)** 6.7×10^{-4} cm; **(b)** 1.23 mm; **(c)** 80 nm; **(d)** 6.72 μm.

6. *Without doing detailed calculations,* arrange the following electromagnetic radiation sources in order of increasing frequency: **(a)** a red traffic light,
   (b) a 91.9 MHz radio transmitter,
   (c) light with a frequency of $3.0 \times 10^{14}\ \mathrm{s}^{-1}$,
   (d) light with a wavelength of 49 nm.

7. How long does it take light from the sun, 93 million miles away, to reach Earth?

8. In astronomy, distances are measured in *light-years*, the distance that light travels in one year. What is the distance of one light-year expressed in kilometers?

Atomic Spectra

9. Use the Balmer equation (8.2) to determine
   (a) the frequency, in s^{-1}, of the radiation corresponding to $n = 5$;
   (b) the wavelength, in nanometers, of the line in the Balmer series corresponding to $n = 7$;
   (c) the value of n corresponding to the Balmer series line at 380 nm.

10. How would the Balmer equation (8.2) have to be modified to predict lines in the infrared spectrum of hydrogen? [*Hint:* Compare equations (8.2) and (8.6).]

11. Use Planck's equation (8.3) to determine
    (a) the energy, in joules per photon, of radiation of frequency $7.39 \times 10^{15}\ \mathrm{s}^{-1}$;
    (b) the energy, in kilojoules per mole, of radiation of frequency $1.97 \times 10^{14}\ \mathrm{s}^{-1}$.

12. Use Planck's equation (8.3) to determine
    (a) the frequency, in hertz, of radiation having an energy of 8.62×10^{-21} J/photon;
    (b) the wavelength, in nanometers, of radiation with 360 kJ/mol of energy.

13. What is ΔE for the transition of an electron from $n = 6$ to $n = 3$ in a Bohr hydrogen atom? What is the frequency of the spectral line produced?

14. What is ΔE for the transition of an electron from $n = 5$ to $n = 2$ in a Bohr hydrogen atom? What is the frequency of the spectral line produced?

15. To what value of n in equation (8.2) does the line in the Balmer series at 389 nm correspond?

16. The Lyman series of the hydrogen spectrum can be represented by the equation

$$\nu = 3.2881 \times 10^{15}\ \mathrm{s}^{-1}\left(\frac{1}{1^2} - \frac{1}{n^2}\right)(\text{where } n = 2, 3, \ldots)$$

(a) Calculate the maximum and minimum wavelength lines, in nanometers, in this series.
(b) What value of n corresponds to a spectral line at 95.0 nm?
(c) Is there a line at 108.5 nm? Explain.

17. Calculate the wavelengths, in nanometers, of the first four lines of the Balmer series of the hydrogen spectrum, starting with the *longest* wavelength component.

18. A line is detected in the hydrogen spectrum at 1880 nm. Is this line in the Balmer series? Explain.

Quantum Theory

19. A certain radiation has a wavelength of 574 nm. What is the energy, in joules, of **(a)** one photon; **(b)** a mole of photons of this radiation?

20. What is the wavelength, in nanometers, of light with an energy content of 1979 kJ/mol? In what portion of the electromagnetic spectrum is this light?

21. *Without doing detailed calculations*, indicate which of the following electromagnetic radiations has the greatest energy per photon and which has the least: **(a)** 662 nm; **(b)** 2.1×10^{-5} cm; **(c)** 3.58 μm; **(d)** 4.1×10^{-6} m.

22. *Without doing detailed calculations*, arrange the following forms of electromagnetic radiation in *increasing* order of energy per mole of photons: **(a)** radiation with $\nu = 3.0 \times 10^{15}\ \mathrm{s}^{-1}$, **(b)** an infrared heat lamp, **(c)** radiation having $\lambda = 7000$ Å, **(d)** dental X-rays.

23. In what region of the electromagnetic spectrum would you expect to find radiation having an energy per photon 100 times that associated with 988 nm radiation?

24. High-pressure sodium vapor lamps are used in street lighting. The two brightest lines in the sodium spectrum are at 589.00 and 589.59 nm. What is the difference in energy per photon of the radiations corresponding to these two lines?

The Photoelectric Effect

25. The lowest-frequency light that will produce the photoelectric effect is called the *threshold frequency*.
(a) The threshold frequency for indium is $9.96 \times 10^{14}\ \mathrm{s}^{-1}$. What is the energy, in joules, of a photon of this radiation?
(b) Will indium display the photoelectric effect with UV light? With infrared light? Explain.

26. The minimum energy required to cause the photoelectric effect in potassium metal is 3.69×10^{-19} J. Will photoelectrons be produced when visible light shines on the surface of potassium? If 400 nm radiation is shone on potassium, what is the velocity of the ejected electrons?

The Bohr Atom

27. Use the description of the Bohr atom given in the text to determine **(a)** the radius, in nanometers, of the sixth Bohr orbit for hydrogen; **(b)** the energy, in joules, of the electron when it is in this orbit.

28. Calculate the increase in **(a)** distance from the nucleus and **(b)** energy when an electron is excited from the first to the third Bohr orbit.

29. What are the **(a)** frequency, in s^{-1}, and **(b)** wavelength, in nanometers, of the light emitted when the electron in a hydrogen atom drops from the energy level $n = 7$ to $n = 4$? **(c)** In what portion of the electromagnetic spectrum is this light?

30. *Without doing detailed calculations*, indicate which of the following electron transitions requires the greatest amount of energy to be *absorbed* by a hydrogen atom: from **(a)** $n = 1$ to $n = 2$; **(b)** $n = 2$ to $n = 4$; **(c)** $n = 3$ to $n = 9$; **(d)** $n = 10$ to $n = 1$.

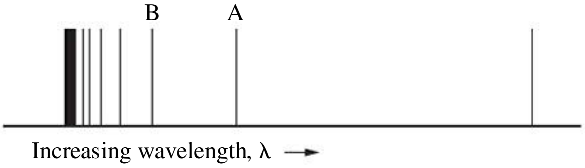
31. For the Bohr hydrogen atom determine
(a) the radius of the orbit $n = 4$
(b) whether there is an orbit having a radius of 4.00 Å
(c) the energy level corresponding to $n = 8$
(d) whether there is an energy level at -2.5×10^{-17} J

32. *Without doing detailed calculations*, indicate which of the following electron transitions in the hydrogen atom results in the emission of light of the longest wavelength. **(a)** $n = 4$ to $n = 3$; **(b)** $n = 1$ to $n = 2$; **(c)** $n = 1$ to $n = 6$; **(d)** $n = 3$ to $n = 2$.

33. What electron transition in a hydrogen atom, starting from the orbit $n = 7$, will produce light of wavelength 410 nm?

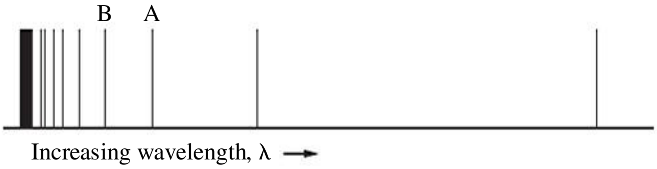
34. What electron transition in a hydrogen atom, ending in the orbit $n = 3$, will produce light of wavelength 1090 nm?

35. The emission spectrum below for a one-electron (hydrogen-like) species in the gas phase shows all the lines, before they merge together, resulting from transitions to the ground state from higher energy states. Line A has a wavelength of 103 nm.



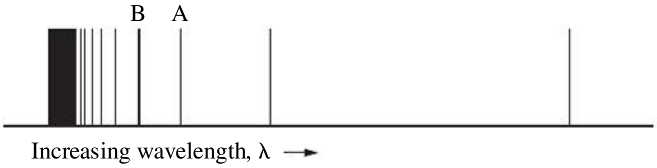
(a) What are the upper and lower principal quantum numbers corresponding to the lines labeled A and B? **(b)** Identify the one-electron species that exhibits the spectrum.

36. The emission spectrum below for a one-electron (hydrogen-like) species in the gas phase shows all the lines, before they merge together, resulting from transitions to the first excited state from higher energy states. Line A has a wavelength of 434 nm.



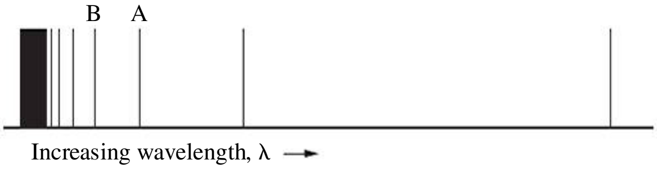
(a) What are the upper and lower principal quantum numbers corresponding to the lines labeled A and B? **(b)** Identify the one-electron species that exhibits the spectrum.

37. The emission spectrum below for a one-electron (hydrogen-like) species in the gas phase shows all the lines, before they merge together, resulting from transitions to the first excited state from higher energy states. Line A has a wavelength of 27.1 nm.



(a) What are the upper and lower principal quantum numbers corresponding to the lines labeled A and B? **(b)** Identify the one-electron species that exhibits the spectrum.

38. The emission spectrum below for a one-electron (hydrogen-like) species in the gas phase shows all the lines, before they merge together, resulting from transitions to the ground state from higher energy states. Line A has a wavelength of 10.8 nm.



(a) What are the upper and lower principal quantum numbers corresponding to the lines labeled A and B? **(b)** Identify the one-electron species that exhibits the spectrum.

Wave–Particle Duality

39. Which must possess a greater velocity to produce matter waves of the same wavelength (such as 1 nm), protons or electrons? Explain your reasoning.

40. What must be the velocity, in meters per second, of a beam of electrons if they are to display a de Broglie wavelength of 1 μm?

41. Calculate the de Broglie wavelength, in nanometers, associated with a 145 g baseball traveling at a speed of 168 km/h. How does this wavelength compare with typical nuclear or atomic dimensions?

42. What is the wavelength, in nanometers, associated with a 1000 kg automobile traveling at a speed of 25 m s^{-1}, that is, considering the automobile to be a matter wave? Comment on the feasibility of an experimental measurement of this wavelength.

The Heisenberg Uncertainty Principle

43. Describe how the Bohr model of the hydrogen atom appears to violate the Heisenberg uncertainty principle.

44. Although Einstein made some early contributions to quantum theory, he was never able to accept the Heisenberg uncertainty principle. He stated, "God does not play dice with the Universe." What do you suppose Einstein meant by this remark? In reply to Einstein's remark, Niels Bohr is supposed to have said, "Albert, stop telling God what to do." What do you suppose Bohr meant by this remark?

45. A proton is accelerated to one-tenth the velocity of light, and this velocity can be measured with a precision of 1%. What is the uncertainty in the position of this proton?

46. Show that the uncertainty principle is not significant when applied to large objects such as automobiles. Assume that m is precisely known; assign a reasonable value to either the uncertainty in position or the uncertainty in velocity, and estimate a value of the other.

47. What must be the velocity of electrons if their associated wavelength is to equal the radius of the first Bohr orbit of the hydrogen atom?

48. What must be the velocity of electrons if their associated wavelength is to equal the *longest* wavelength line in the Lyman series? [*Hint:* Refer to Figure 8-14.]

Wave Mechanics

49. A standing wave in a string 42 cm long has a total of six nodes (including those at the ends). What is the wavelength, in centimeters, of this standing wave?

50. What is the length of a string that has a standing wave with four nodes (including those at the ends) and $\lambda = 17$ cm?

51. Calculate the wavelength of the electromagnetic radiation required to excite an electron from the ground state to the level with $n = 4$ in a one-dimensional box 50. pm long.

52. An electron in a one-dimensional box requires a wavelength of 618 nm to excite an electron from the $n = 2$ level to the $n = 4$ level. Calculate the length of the box.

53. An electron in a 20.0 nm box is excited from the ground state into a higher energy state by absorbing a photon of wavelength 8.60×10^{-5} m. Determine the final energy state.

54. Calculate the wavelength of the electromagnetic radiation required to excite a proton from the ground state to the level with $n = 4$ in a one-dimensional box 50. pm long.

55. Describe some of the differences between the orbits of the Bohr atom and the orbitals of the wave mechanical atom. Are there any similarities?

56. The greatest probability of finding the electron in a small-volume element of the 1*s* orbital of the hydrogen atom is at the nucleus. Yet the most probable distance of the electron from the nucleus is 53 pm. How can you reconcile these two statements?

Quantum Numbers and Electron Orbitals

57. Select the correct answer and explain your reasoning. An electron having $n = 3$ and $m_\ell = 0$ **(a)** must have $m_s = +\frac{1}{2}$; **(b)** must have $\ell = 1$; **(c)** may have $\ell = 0, 1$, or 2; **(d)** must have $\ell = 2$.

58. Write an acceptable value for each of the missing quantum numbers.

(a) $n = 3, \ell = ?, m_\ell = 2, m_s = +\frac{1}{2}$

(b) $n = ?, \ell = 2, m_\ell = 1, m_s = -\frac{1}{2}$

(c) $n = 4, \ell = 2, m_\ell = 0, m_s = ?$

(d) $n = ?, \ell = 0, m_\ell = ?, m_s = ?$

59. What type of orbital (i.e., 3*s*, 4*p*, ...) is designated by these quantum numbers?

(a) $n = 5, \ell = 1, m_\ell = 0$

(b) $n = 4, \ell = 2, m_\ell = -2$

(c) $n = 2, \ell = 0, m_\ell = 0$

60. Which of the following statements is (are) correct for an electron with $n = 4$ and $m_\ell = 2$? Explain.

(a) The electron is in the fourth principal shell.

(b) The electron may be in a *d* orbital.

(c) The electron may be in a *p* orbital.

(d) The electron must have $m_s = +\frac{1}{2}$.

61. Concerning the electrons in the shells, subshells, and orbitals of an atom, how many can have

(a) $n = 4, \ell = 2, m_\ell = 1$, and $m_s = +\frac{1}{2}$?

(b) $n = 4, \ell = 2$, and $m_\ell = 1$?

(c) $n = 4$ and $\ell = 2$?

(d) $n = 4$?

(e) $n = 4, \ell = 2$, and $m_s = +\frac{1}{2}$?

62. Concerning the concept of subshells and orbitals,

(a) How many subshells are found in the $n = 3$ level?

(b) What are the names of the subshells in the $n = 3$ level?

(c) How many orbitals have the values $n = 4$ and $\ell = 3$?

(d) How many orbitals have the values $n = 3, \ell = 2$, and $m_\ell = -2$?

(e) What is the total number of orbitals in the $n = 4$ level?

The Shapes of Orbitals and Radial Probabilities

63. Calculate the finite value of *r*, in terms of a_0, at which the node occurs in the wave function of the 2*s* orbital of a hydrogen atom.

64. Calculate the finite value of *r*, in terms of a_0, at which the node occurs in the wave function of the 2*s* orbital of a Li^{2+} ion.

65. Show that the probability of finding a $2p_y$ electron in the *xz* plane is zero.

66. Show that the probability of finding a $3d_{xz}$ electron in the *xy* plane is zero.

67. Prepare a two-dimensional plot of $Y(\theta, \phi)$ for the p_y orbital in the *xy* plane.

68. Prepare a two-dimensional plot of $Y^2(\theta, \phi)$ for the p_y orbital in the *xy* plane.

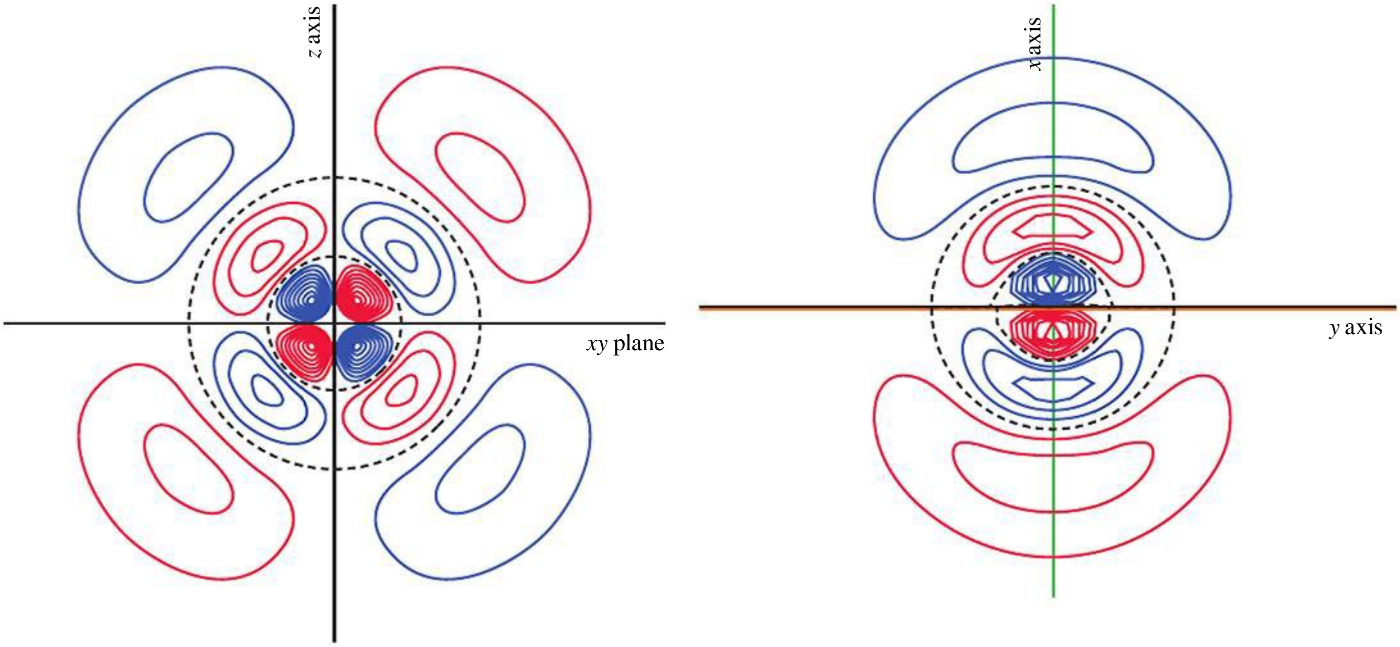
69. Using a graphical method, show that in a hydrogen atom the radius at which there is a maximum probability of finding an electron is a_0 (53 pm).

70. Use a graphical method or some other means to show that in a Li^{2+} ion, the radius at which there is a maximum probability of finding an electron is $\frac{a_0}{3}$ (18 pm).

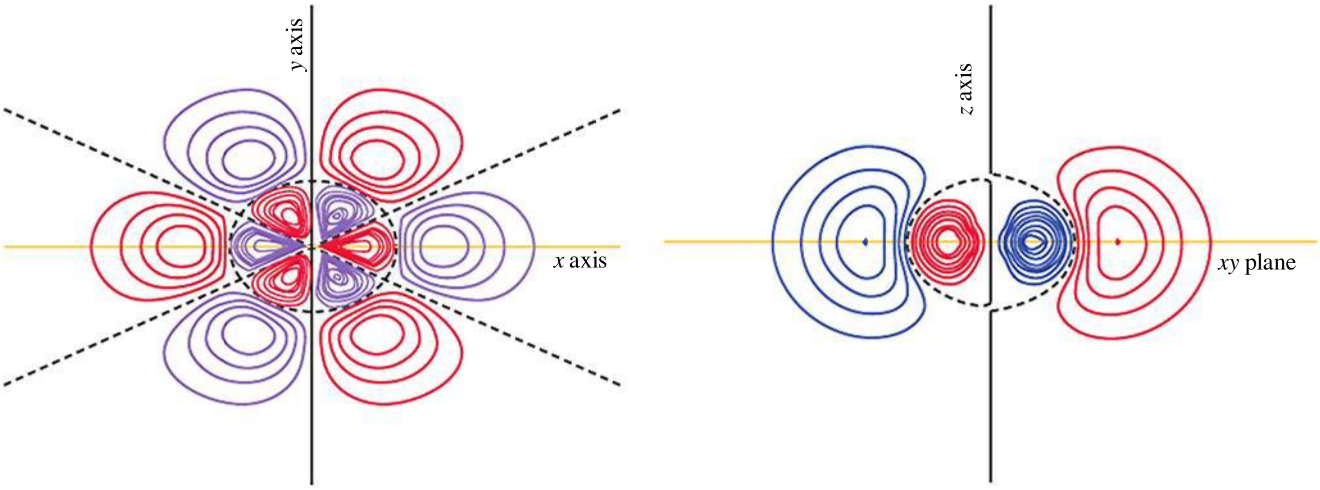
71. Identify the orbital that has **(a)** one radial node and one angular node; **(b)** no radial nodes and two angular nodes; **(c)** two radial nodes and three angular nodes.

72. Identify the orbital that has **(a)** two radial nodes and one angular node; **(b)** five radial nodes and zero angular nodes; **(c)** one radial node and four angular nodes.

73. A contour map for an atomic orbital of hydrogen is shown at the top of page 355 for the *xy* and *xz* planes. Identify the orbital.



74. A contour map for an atomic orbital of hydrogen is shown below for the *xy* and *xz* planes. Identify the type $(s, p, d, f, g \ldots)$ of orbital.



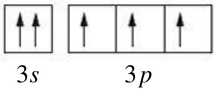
Electron Configurations

75. On the basis of the periodic table and rules for electron configurations, indicate the number of **(a)** $2p$ electrons in N; **(b)** $4s$ electrons in Rb; **(c)** $4d$ electrons in As; **(d)** $4f$ electrons in Au; **(e)** unpaired electrons in Pb; **(f)** elements in group 14 of the periodic table; **(g)** elements in the sixth period of the periodic table.

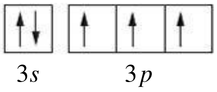
76. Based on the relationship between electron configurations and the periodic table, give the number of **(a)** outer-shell electrons in an atom of Sb; **(b)** electrons in the fourth principal electronic shell of Pt; **(c)** elements whose atoms have six outer-shell electrons; **(d)** unpaired electrons in an atom of Te; **(e)** transition elements in the sixth period.

77. Which of the following is the correct orbital diagram for the ground-state electron configuration of phosphorus? Explain what is wrong with each of the others.

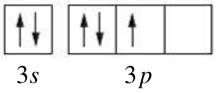
(a) [Ne]



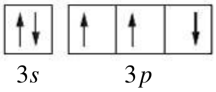
(b) [Ne]



(c) [Ne]

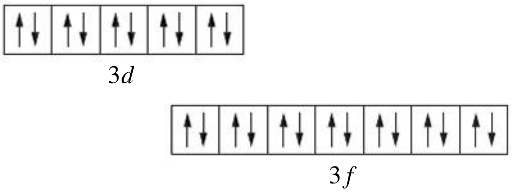


(d) [Ne]

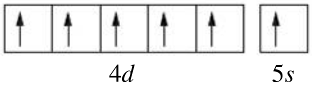


78. Which of the following is the correct orbital diagram for the ground-state electron configuration of molybdenum? Explain what is wrong with each of the others.

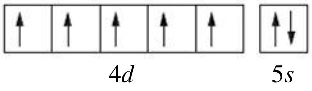
(a) [Ar]



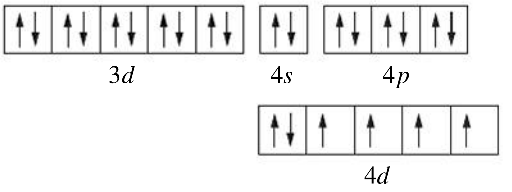
(b) [Kr]



(c) [Kr]



(d) [Ar]



79. Use the basic rules for electron configurations to indicate the number of **(a)** unpaired electrons in an atom of P; **(b)** 3*d* electrons in an atom of Br; **(c)** 4*p* electrons in an atom of Ge; **(d)** 6*s* electrons in an atom of Ba; **(e)** 4*f* electrons in an atom of Au.

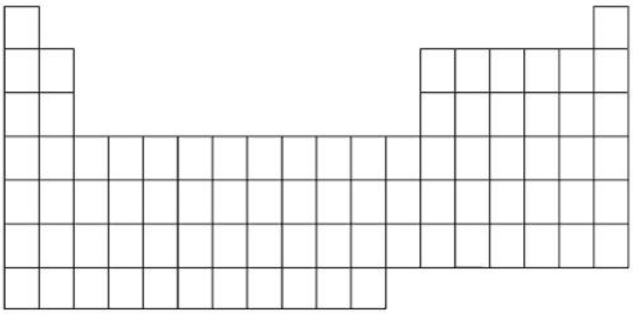
80. Use orbital diagrams to show the distribution of electrons among the orbitals in **(a)** the 4*p* subshell of Br; **(b)** the 3*d* subshell of Co^{2+}, given that the two electrons lost are 4*s*; **(c)** the 5*d* subshell of Pb.

81. The recently discovered element 114 should most closely resemble Pb.

(a) Write the electron configuration of Pb.

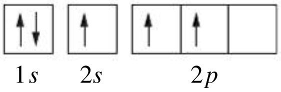
(b) Propose a plausible electron configuration for element 114.

82. Without referring to any tables or listings in the text, mark an appropriate location in the blank periodic table provided for each of the following: **(a)** the fifth-period noble gas; **(b)** a sixth-period element whose atoms have three unpaired *p* electrons; **(c)** a *d*-block element having one 4*s* electron; **(d)** a *p*-block element that is a metal.

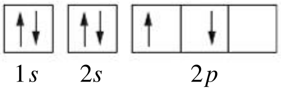


83. Which of the following electron configurations corresponds to the ground state and which to an excited state?

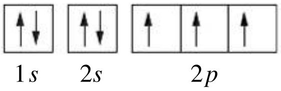
(a) [B]



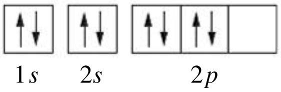
(b) [C]



(c) [N]

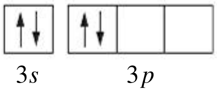


(d) [O]

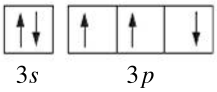


84. To what neutral atom do the following valence-shell configurations correspond? Indicate whether the configuration corresponds to the ground state or an excited state.

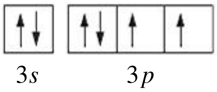
(a)



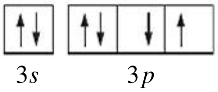
(b)



(c)



(d)



85. What is the expected ground-state electron configuration for each of the following elements? **(a)** mercury; **(b)** calcium; **(c)** polonium; **(d)** tin; **(e)** tantalum; **(f)** iodine.

86. What is the expected ground-state electron configuration for each of the following elements? **(a)** tellurium; **(b)** cesium; **(c)** selenium; **(d)** platinum; **(e)** osmium; **(f)** chromium.

87. The following electron configurations correspond to the ground states of certain elements. Name each element. **(a)** $[Rn]7s^2 6d^2$; **(b)** $[He]2s^2 2p^2$; **(c)** $[Ar]3d^3 4s^2$; **(d)** $[Kr]4d^{10} 5s^2 5p^4$; **(e)** $[Xe]4f^2 6s^2 6p^1$.

88. The following electron configurations correspond to the ground states of certain elements. Name each element. **(a)** $[Ar]3d^{10} 4s^2 4p^3$; **(b)** $[Ne]3s^2 3p^4$; **(c)** $[Ar]3d^1 4s^2$; **(d)** $[Kr]4d^6 5s^2$; **(e)** $[Xe]4f^{12} 6s^2$.

Integrative and Advanced Exercises

89. Derive the Balmer equation from equation (8.6).

90. Electromagnetic radiation can be transmitted through a vacuum or empty space. Can heat be similarly transferred? Explain.

91. The *work function* is the energy that must be supplied to cause the release of an electron from a photoelectric material. The corresponding photon frequency is the threshold frequency. The higher the energy of the incident light, the more kinetic energy the electrons have in moving away from the surface. The work function for mercury is equivalent to 435 kJ/mol photons.
(a) Can the photoelectric effect be obtained with mercury by using visible light? Explain.
(b) What is the kinetic energy, in joules, of the ejected electrons when light of 215 nm strikes a mercury surface?
(c) What is the velocity, in meters per second, of the ejected electrons in part (b)?

92. Infrared lamps are used in cafeterias to keep food warm. How many photons per second are produced by an infrared lamp that consumes energy at the rate of 95 W and is 14% efficient in converting this energy to infrared radiation? Assume that the radiation has a wavelength of 1525 nm.

93. In 5.0 s, a 75 watt light source emits 9.91×10^{20} photons of a monochromatic (single wavelength) radiation. What is the color of the emitted light?

94. In everyday usage, the term "quantum jump" describes a change of a very significant magnitude compared to more gradual, incremental changes; it is similar in meaning to the term "a sea change." Does quantum jump have the same meaning when applied to events at the atomic or molecular level? Explain.

95. The Pfund series of the hydrogen spectrum has as its *longest* wavelength component a line at 7400 nm. Describe the electron transitions that produce this series. That is, give a Bohr quantum number that is common to this series.

96. Between which two orbits of the Bohr hydrogen atom must an electron fall to produce light of wavelength 1876 nm?

97. Use appropriate relationships from the chapter to determine the wavelength of the line in the emission spectrum of He^+ produced by an electron transition from $n = 5$ to $n = 2$.

98. Draw an energy-level diagram that represents all the possible lines in the emission spectrum of hydrogen atoms produced by electron transitions, in one or more steps, from $n = 5$ to $n = 1$.

99. An atom in which just one of the outer-shell electrons is excited to a very high quantum level n is called a "high Rydberg" atom. In some ways, all these atoms resemble a Bohr hydrogen atom with its electron in a high-numbered orbit. Explain why you might expect this to be the case.

100. If all other rules governing electron configurations were valid, what would be the electron configuration of cesium if **(a)** there were *three* possibilities for electron spin; **(b)** the quantum number ℓ could have the value n?

101. Ozone, O_3, absorbs ultraviolet radiation and dissociates into O_2 molecules and O atoms: $O_3 + h\nu \longrightarrow O_2 + O$. A 1.00 L sample of air at 22 °C and 748 mmHg contains 0.25 ppm of O_3. How much energy, in joules, must be absorbed if all the O_3 molecules in the sample of air are to dissociate? Assume that each photon absorbed causes one O_3 molecule to dissociate, and that the wavelength of the radiation is 254 nm.

102. Radio signals from *Voyager 1* in the 1970s were broadcast at a frequency of 8.4 GHz. On Earth, this radiation was received by an antenna able to detect signals as weak as 4×10^{-21} W. How many photons per second does this detection limit represent?

103. Certain metal compounds impart colors to flames—sodium compounds, yellow; lithium, red; barium, green—and flame tests can be used to detect these elements. **(a)** At a flame temperature of 800 °C, can collisions between gaseous atoms with average kinetic energies supply the energies required for the emission of visible light? **(b)** If not, how do you account for the excitation energy?

104. The angular momentum of an electron in the Bohr hydrogen atom is mur, where m is the mass of the electron, u, its velocity, and r, the radius of the Bohr orbit. The angular momentum can have only the values $nh/2\pi$, where n is an integer (the number of the Bohr orbit). Show that the *circumferences* of the various Bohr orbits are integral multiples of the de Broglie wavelengths of the electron treated as a matter wave.

105. A molecule of chlorine can be dissociated into atoms by absorbing a photon of sufficiently high energy. Any excess energy is translated into kinetic energy as the atoms recoil from one another. If a molecule of chlorine at rest absorbs a photon of 300 nm wavelength, what will be the velocity of the two recoiling atoms? Assume that the excess energy is equally divided between the two atoms. The bond energy of Cl_2 is 242.6 kJ mol^{-1}.

106. Refer to the Integrative Example. Determine whether or not $n = 138$ is a bound state. If it is, what sort of state is it? What is the radius of the orbit and how many revolutions per second does the electron make about the nucleus?

107. Using the relationships given in Table 8.1, find the finite values of r, in terms of a_0, of the nodes for a 3*s* orbital.

108. Use a graphical method or some other means to determine the radius at which the probability of finding a 2*s* orbital is maximum.

109. Using the relationships in Table 8.1, prepare a sketch of the 95% probability surface of a $4p_x$ orbital.

110. Show that the volume of a spherical shell of radius r and thickness dr is $4\pi r^2 dr$. [*Hint*: This exercise requires calculus.]

111. In the ground state of a hydrogen atom, what is the probability of finding an electron anywhere in a sphere of radius **(a)** a_0, or **(b)** $2a_0$? [*Hint*: This exercise requires calculus.]

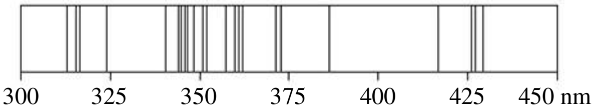
112. When atoms in excited states collide with unexcited atoms they can transfer their excitation energy to those atoms. The most efficient energy transfer occurs when the excitation energy matches the energy of an excited state in the unexcited atom. Assuming that we have a collection of excited hydrogen atoms in the $2s^1$ excited state, are there any transitions of He^+ that could be most efficiently excited by the hydrogen atoms?

Feature Problems

113. We have noted that an emission spectrum is a kind of "atomic fingerprint." The various steels are alloys of iron and carbon, usually containing one or more other metals. Based on the principal lines of their atomic spectra, which of the metals in the table below are likely to be present in a steel sample whose hypothetical emission spectrum is pictured? Is it likely that still other metals are present in the sample? Explain.

Principal Spectral Lines of Some Period 4 Transition Metals (nm)

V	306.64	309.31	318.40	318.54	327.11	437.92	438.47	439.00
Cr	357.87	359.35	360.53	361.56	425.44	427.48	428.97	520.45
Mn	257.61	259.37	279.48	279.83	403.08	403.31	403.45	
Fe	344.06	358.12	372.00	373.49	385.99			
Ni	341.48	344.63	345.85	346.17	349.30	351.51	352.45	361.94



▲ **Hypothetical emission spectrum**
In a real spectrum, the photographic images of the spectral lines would differ in depth and thickness depending on the strengths of the emissions producing them. Some of the spectral lines would not be seen because of their faintness.

114. Balmer seems to have deduced his formula for the visible spectrum of hydrogen just by manipulating numbers. A more common scientific procedure is to graph experimental data and then find a mathematical equation to describe the graph. Show that equation (8.2) describes a straight line. Indicate which variables must be plotted, and determine the numerical values of the slope and intercept of this line. Use data from Figure 8-10 to confirm that the four lines in the visible spectrum of hydrogen fall on the straight-line graph.

115. Follow up on the dartboard analogy of Figure 8-34 by plotting a graph of the scoring summary tabulated below. That is, plot the number of hits as a function of the scoring ring: 50, 40, ... What illustration in the text does this plot most resemble? Explain similarities and differences between the two.

Summary of Scoring (1500 darts)

Darts	Score
200	"50"
300	"40"
400	"30"
250	"20"
200	"10"
150	off the board

116. Emission and absorption spectra of the hydrogen atom exhibit line spectra characteristic of quantized systems. In an absorption experiment, a sample of hydrogen atoms is irradiated with light with wavelengths ranging from 100 to 1000 nm. In an emission spectrum experiment, the hydrogen atoms are excited through an energy source that provides a range of energies from 1230 to 1240 kJ mol^{-1} to the atoms. Assume that the absorption spectrum is obtained at room temperature, when all atoms are in the ground state.

(a) Calculate the position of the lines in the absorption spectrum.

(b) Calculate the position of the lines in the emission spectrum.

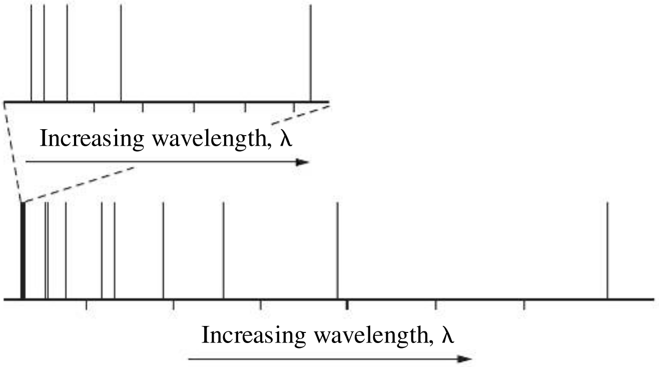
(c) Compare the line spectra observed in the two experiments. In particular, will the number of lines observed be the same?

117. Diffraction of radiation takes place when the distance between the scattering centers is comparable to the wavelength of the radiation.

(a) What velocity must helium atoms possess to be diffracted by a film of silver atoms in which the spacing is 100 pm?

(b) Electrons accelerated through a certain potential are diffracted by a thin film of gold. Would you expect a beam of protons accelerated through the same potential to be diffracted when it strikes the film of gold? If not, what would you expect to see instead?

118. The emission spectrum below is for hydrogen atoms in the gas phase. The spectrum is of the first few emission lines from principal quantum number 6 down to all possible lower levels.



Not all possible de-excitations are possible; the transitions are governed by what is known as a *selection rule*. The selection rule states that the allowed transitions correspond to Δn being arbitrary while $\Delta \ell = \pm 1$. This selection rule can be understood in terms of conservation of momentum, since a photon has an angular momentum of unity. Using this selection rule, identify the transitions, in terms of the types of orbital (s, p, d, f), involved, that are observed in the spectrum shown on page 358.

In the presence of a magnetic field, the lines split into more lines according to the magnetic quantum number. The selection rule for transitions between different magnetic quantum numbers is $\Delta m_\ell = 0$ and ± 1. Identify the line(s) in the spectrum that splits into the greatest number of lines.

Self-Assessment Exercises

119. In your own words, define the following terms or symbols: **(a)** λ; **(b)** ν; **(c)** h; **(d)** ψ; **(e)** principal quantum number, n.

120. Briefly describe each of the following ideas or phenomena: **(a)** atomic (line) spectrum; **(b)** photoelectric effect; **(c)** matter wave; **(d)** Heisenberg uncertainty principle; **(e)** electron spin; **(f)** Pauli exclusion principle; **(g)** Hund's rule; **(h)** orbital diagram; **(i)** electron charge density; **(j)** radial electron density.

121. Explain the important distinctions between each pair of terms: **(a)** frequency and wavelength; **(b)** ultraviolet and infrared light; **(c)** continuous and discontinuous spectra; **(d)** traveling and standing waves; **(e)** quantum number and orbital; **(f)** *spdf* notation and orbital diagram; **(g)** *s* block and *p* block; **(h)** main group and transition element; **(i)** the ground state and excited state of a hydrogen atom.

122. Describe two ways in which the orbitals of multielectron atoms resemble hydrogen orbitals and two ways in which they differ from hydrogen orbitals.

123. Explain the phrase *effective nuclear charge*. How is this related to the shielding effect?

124. With the help of sketches, explain the difference between a p_x, p_y, and p_z orbital.

125. With the help of sketches, explain the difference between a $2p_z$ and $3p_z$ orbital.

126. If traveling at equal speeds, which of the following matter waves has the longest wavelength? Explain. **(a)** electron; **(b)** proton; **(c)** neutron; **(d)** α particle (He^{2+}).

127. For electromagnetic radiation transmitted through a vacuum, state whether each of the following properties is directly proportional to, inversely proportional to, or independent of the frequency: **(a)** velocity; **(b)** wavelength; **(c)** energy per mole. Explain.

128. Sir James Jeans described the photoelectric effect in this way: "It not only prohibits killing two birds with one stone but also the killing of one bird with two stones." By referring to the margin note on page 303, comment on the appropriateness of this analogy.

129. Construct a concept map representing the ideas of modern quantum mechanics.

130. Construct a concept map representing the atomic orbitals of hydrogen and their properties.

131. Construct a concept map for the configurations of multielectron atoms.

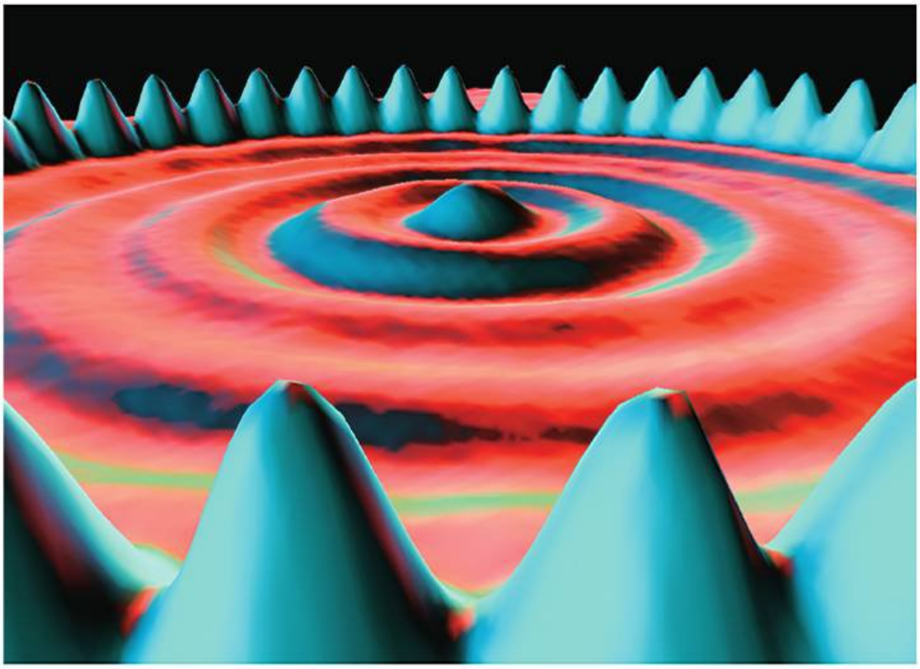
The Periodic Table and Some Atomic Properties

CONTENTS

9-1 Classifying the Elements: The Periodic Law and the Periodic Table
9-2 Metals and Nonmetals and Their Ions
9-3 Sizes of Atoms and Ions
9-4 Ionization Energy
9-5 Electron Affinity
9-6 Magnetic Properties
9-7 Periodic Properties of the Elements



A scanning tunneling microscope image of 48 iron atoms adsorbed onto a surface of copper atoms. The iron atoms were moved into position with the tip of the scanning tunneling microscope in order to create a barrier that forced some electrons of the copper atoms into a quantum state seen here as circular rings of electron density. The colors are from the computer rendering of the image. In this chapter we discuss the periodic table and the properties of atoms and ions.

Chemists value the periodic table as a means of organizing their field, and they would have continued to use it even if they had never figured out why it works. The underlying rationale of the periodic table was discovered about 50 years after the table was proposed.

The basis of the periodic table is the electron configurations of the elements, a topic we studied in Chapter 8. In this chapter, we will use the table as a backdrop for a discussion of some properties of elements, including atomic radii, ionization energies, and electron affinities. These atomic properties also arise in the discussion of chemical bonding in the following two chapters, and the periodic table itself will be our indispensable guide throughout much of the remainder of the text.

9-1 Classifying the Elements: The Periodic Law and the Periodic Table

In 1869, Dmitri Mendeleev and Lothar Meyer independently proposed the **periodic law**:

> When the elements are arranged in order of increasing atomic mass, certain sets of properties recur periodically.

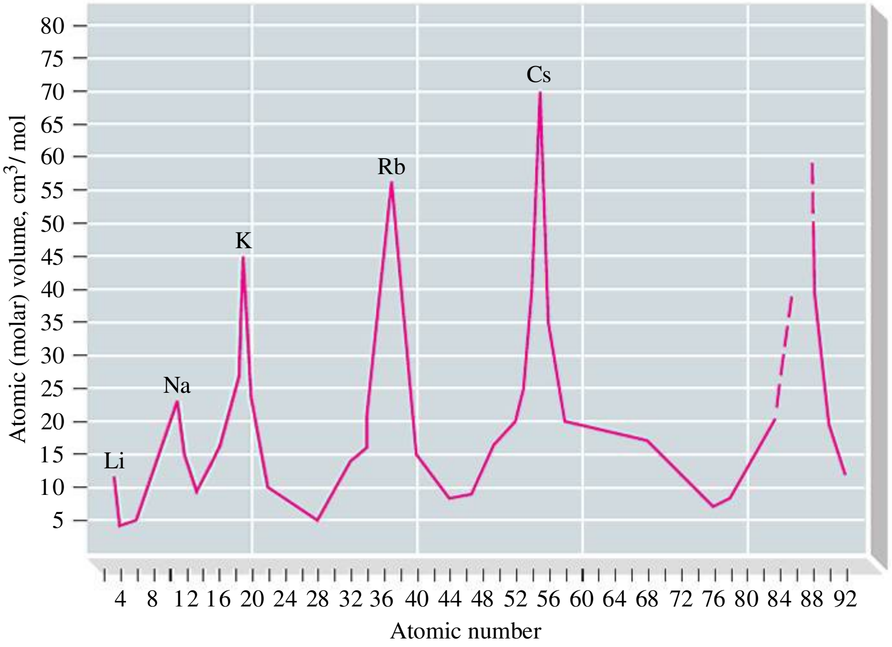
Meyer based his periodic law on the property called atomic volume—the atomic mass of an element divided by the density of its solid form. We now just call this property *molar volume*.

$$\text{atomic (molar) volume (cm}^3\text{/mol)} = \text{molar mass (g/mol)} \times 1/d\,(\text{cm}^3\text{/g}) \qquad \textbf{(9.1)}$$

Meyer presented his results as a graph of atomic volume against atomic mass. Now it is customary to plot his results as molar volume against atomic number, as seen in Figure 9-1. Notice how high atomic volumes recur periodically for the alkali metals Li, Na, K, Rb, and Cs. Later, Meyer examined other physical properties of the elements and their compounds, such as hardness, compressibility, and boiling points, and found that these also vary periodically.

Mendeleev's Periodic Table

As previously described, the periodic table is a tabular arrangement of the elements that groups similar elements together. Mendeleev's work attracted more attention than Meyer's for two reasons: He left blank spaces in his table for undiscovered elements, and he corrected some atomic mass values. The blanks in his table came at atomic masses 44, 68, 72, and 100 for the elements we now know as scandium, gallium, germanium, and technetium. Two of the atomic mass values he corrected were those of indium and uranium.



▲ FIGURE 9-1

An illustration of the periodic law—variation of atomic volume with atomic number

This adaptation of Meyer's 1870 graph plots atomic volumes against atomic numbers. Of course, a number of elements, such as the noble gases, were undiscovered in Meyer's time. The graph shows peaks at the alkali metals (Li, Na, K, and so on). Nonmetals fall on the ascending portions of the curve and metals at the peaks, on the descending portions, and in the valleys.

▲ Dmitri Mendeleev (1834–1907)
Mendeleev's discovery of the periodic table came from his attempts to systematize properties of the elements for presentation in a chemistry textbook. His highly influential book went through eight editions in his lifetime and five more after his death.

In his periodic table Mendeleev arranged the elements into eight groups (Gruppe) and twelve rows (Reihen). The formulas are written as Mendeleev wrote them. R^2O, RO, and so on, are formulas of the element oxides (such as Li_2O, MgO, . . .); RH^4, RH^3, and so forth, are formulas of the element hydrides (such as CH_4, NH_3, . . .).

▶ Other properties of the alkali metals are discussed in Section 9-7.

In Mendeleev's table, similar elements fall in vertical groups, and the properties of the elements change gradually from top to bottom in the group. As an example, we have seen that the alkali metals (Mendeleev's group I) have high molar volumes (Fig. 9-1). They also have low melting points, which decrease in the order

$$\text{Li}\,(174\,°\text{C}) > \text{Na}\,(97.8\,°\text{C}) > \text{K}\,(63.7\,°\text{C}) > \text{Rb}\,(38.9\,°\text{C}) > \text{Cs}\,(28.5\,°\text{C})$$

In their compounds, the alkali metals exhibit the oxidation state +1, forming ionic compounds, such as NaCl, KBr, CsI, Li_2O, and so on.

Discovery of New Elements

Three elements predicted by Mendeleev were discovered shortly after the appearance of his 1871 periodic table (gallium, 1875; scandium, 1879; germanium, 1886). Table 9.1 illustrates how closely Mendeleev's predictions for eka-silicon agree with the observed properties of the element germanium, discovered in 1886. Often, new ideas in science take hold slowly, but the success of Mendeleev's predictions stimulated chemists to adopt his table fairly quickly.

▶ The term *eka* is derived from Sanskrit and means "first." That is, eka-silicon means, literally, "first comes silicon" (and then comes the unknown element).

TABLE 9.1 Properties of Germanium: Predicted and Observed

Property	Predicted Eka-silicon (1871)	Observed Germanium (1886)
Atomic mass	72	72.6
Density, g/cm^3	5.5	5.47
Color	dirty gray	grayish white
Density of oxide, g/cm^3	EsO_2: 4.7	GeO_2: 4.703
Boiling point of chloride	$EsCl_4$: below 100 °C	$GeCl_4$: 86 °C
Density of chloride, g/cm^3	$EsCl_4$: 1.9	$GeCl_4$: 1.887

One group of elements that Mendeleev did not anticipate was the noble gases. He left no blanks for them. William Ramsay, their discoverer, proposed placing them in a separate group of the table. Because argon, the first noble gas discovered (1894), had an atomic mass greater than that of chlorine and comparable to that of potassium, Ramsay placed the new group, which he called group 0, between the halogen elements (group VII) and the alkali metals (group I).

Atomic Number as the Basis for the Periodic Law

Mendeleev placed certain elements out of the order of increasing atomic mass to get them into the proper groups of his periodic table. He assumed this was because of errors in atomic masses. With improved methods of determining atomic masses and with the discovery of argon (group 0, atomic mass 39.9), which was placed ahead of potassium (group I, atomic mass 39.1), it became clear that a few elements might always remain "out of order." At the time, these out-of-order placements were justified by chemical evidence. Elements were placed in the groups that their chemical behavior dictated. There was no theoretical explanation for this reordering. Matters changed in 1913 as a result of some research by Henry G. J. Moseley on the X-ray spectra of the elements.

▲ **Henry G. J. Moseley (1887–1915)**
Moseley was one of a group of brilliant scientists whose careers were launched under Ernest Rutherford. He was tragically killed at Gallipoli, in Turkey, during World War I.

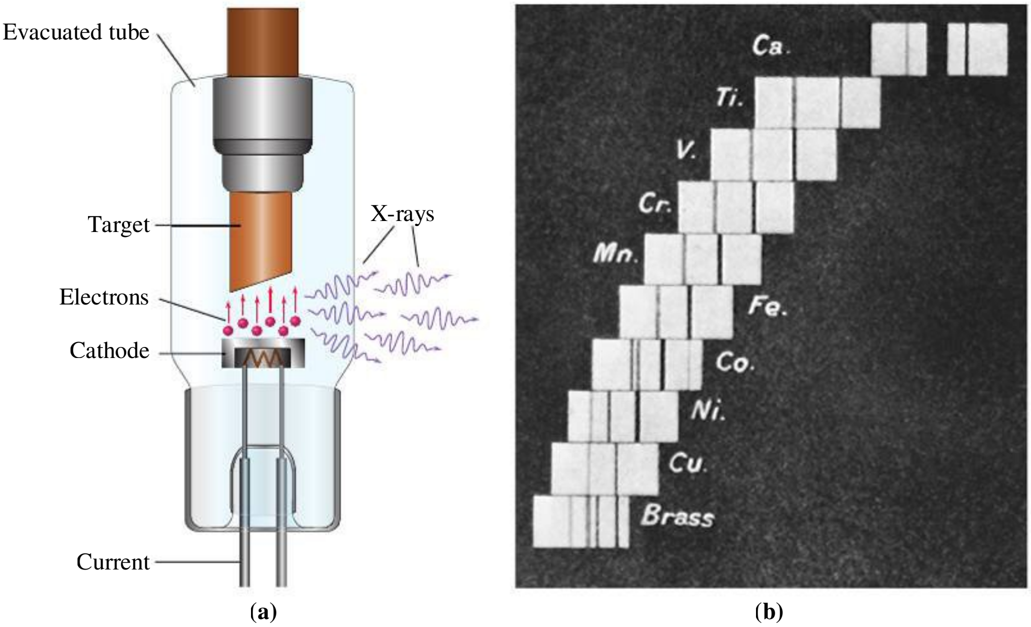
As we learned in Chapter 2, X-rays are a high-frequency form of electromagnetic radiation produced when a cathode-ray (electron) beam strikes the anode of a cathode-ray tube (see Figure 9-2a). The anode is called the *target*. Moseley was familiar with Bohr's atomic model, and explained X-ray emission in the following way. If the bombarding electrons have sufficient energy, they can eject electrons from the inner orbitals of target metal atoms. Electrons from higher orbitals then drop down to fill the vacancies, emitting X-ray photons with energies corresponding to the difference in energy between the originating level and the vacancy level (see Figure 8-13). Moseley reasoned that because the energies of electron orbitals depend on the nuclear charge, the frequencies of emitted X-rays should depend on the nuclear charges of atoms in the target. Using techniques newly developed by the father–son team of W. Henry Bragg and W. Lawrence Bragg, Moseley obtained photographic images of X-ray spectra and assigned frequencies to the spectral lines. His spectra for the elements from Ca to Zn are reproduced in Figure 9-2(b).

Moseley was able to correlate X-ray frequencies to numbers equal to the nuclear charges and corresponding to the positions of elements in Mendeleev's periodic table. For example, aluminum, the thirteenth element in the table, was assigned an *atomic number* of 13. Moseley's equation is $\nu = A(Z - b)^2$, where ν is the X-ray frequency, Z is the atomic number, and A and b are constants. Moseley used this relationship to predict three new elements ($Z = 43, 61$, and 75), which were discovered in 1937, 1945, and 1925, respectively. Also, he proved that in the portion of the periodic table with which he worked (from $Z = 13$ to $Z = 79$), there could be no additional new elements beyond those three. All available atomic numbers had been assigned. From the standpoint of Moseley's work, then, we should restate the periodic law.

Similar properties recur periodically when elements are arranged according to increasing atomic number.

Description of a Modern Periodic Table: The Long Form

Mendeleev's periodic table consisted of 8 groups, but most modern periodic tables are arranged in 18 groups of elements. Let us briefly review the description of the periodic table given in Section 2-6.



▲ FIGURE 9-2
Schematic of an X-ray tube and Moseley's X-ray spectra of several elements
(a) A heated filament emits electrons by a process called thermionic emission. The electrons are accelerated by a high voltage, and collide with the metal target. The highly energetic electrons ionize electrons from the inner shells of the metal atoms of the target. Subsequently, electrons from higher orbitals drop down to occupy the vacancies and in doing so, emit X-ray photons that correspond to the energy difference between the two orbitals. (b) In this photograph from Moseley's 1913 paper, you can see two lines for each element, beginning with Ca at the top. With each successive element, the lines are displaced to the left, the direction of increasing X-ray frequency in these experiments. Where more than two lines appear, the sample contained one or more other elements, or impurities. Notice, for example, that one line in the Co spectrum matches a line in the Fe spectrum, and another matches a line in the Ni spectrum. Brass, which is an alloy of copper and zinc, shows two lines for Cu and two for Zn.

In the periodic table (see inside front cover), the vertical groups bring together elements with similar properties. The horizontal periods of the table are arranged in order of increasing atomic number from left to right. The groups are numbered at the top, and the periods at the extreme left. The first two groups—the *s* block—and the last six groups—the *p* block—together constitute the *main-group elements*. Because they come between the *s* block and the *p* block, the *d* block elements are known as the *transition elements*. The *f* block elements, sometimes called the *inner transition elements*, would extend the table to a width of 32 members if incorporated in the main body of the table. The table would generally be too wide to fit on a printed page, and so the *f* block elements are extracted from the table and placed at the bottom. The 15 elements following barium $(Z = 56)$ are called the *lanthanides*, and the 15 following radon $(Z = 88)$ are called the *actinides*.

9-2 Metals and Nonmetals and Their Ions

In Section 2-6, we established two categories of elements, *metals* and *nonmetals*, and described them in terms of physical properties. Most metals are good conductors of heat and electricity, are malleable and ductile, and have moderate to high melting points. In general, nonmetals are nonconductors of heat and electricity and are nonmalleable (brittle) solids, though a number of nonmetals are gases at room temperature.

Through the color scheme of the periodic table on the inside front cover, we see that the majority of the elements are metals (orange) and that nonmetals (blue) are confined to the right side of the table. The noble gases (purple) are treated as a special group of nonmetals. Metals and nonmetals are often separated by a stairstep diagonal line, and several elements near this line are often called metalloids (green). **Metalloids** are elements that look like metals and in some ways behave like metals but also have some nonmetallic properties.

◀ Metalloids (such as silicon) are semiconductors and materials composed of metalloids play an important role in microcomputer technology.

In the original periodic table, the positions of the elements were based on readily observable physical and chemical properties. In Chapter 8, we learned of the close correlation between electron configurations and the positions of the elements in the table. Thus, it appears that the physical and chemical properties of an element are determined largely by its electron configuration, particularly that of the *valence* (outermost) electronic shell. Adjacent members of a series of main-group elements in the same period (such as P, S, and Cl) have significantly different properties because they differ in their valence-electron configurations. Within a transition series, differences in electron configurations are mostly in inner shells, and so a transition element has some similarities to neighboring transition elements in the same period. In particular we find many similar properties for adjacent members of the same period within the *f* block. In fact, the strong similarities among the lanthanide elements presented a particular challenge to the nineteenth-century chemists who tried to separate and identify them.

Let's now briefly explore a few of the links between electron configurations and some other observations about the elements, starting with the noble gases.

Noble Gases

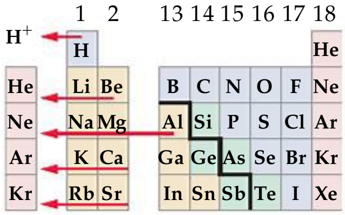
Atoms of the noble gases have the maximum number of electrons permitted in the valence shell of an atom, two in helium ($1s^2$) and eight in the other noble gas atoms (ns^2np^6). These electron configurations are very difficult to alter and seem to confer a high degree of chemical inertness to the noble gases. It is interesting to note, then, that the *s*-block metals, together with Al in group 13, tend to lose enough electrons to acquire the electron configurations of the noble gases. Conversely, nonmetals tend to gain enough electrons to achieve the same configurations.

◀ Compounds containing radon, xenon and krypton have been prepared. Recently, compounds containing argon have also been prepared.

Main-Group Metal Ions

The atoms of elements of groups 1 and 2—the most active metals—have electron configurations that differ from those of the noble gas of the preceding period by only one and two electrons in the *s* orbital of a new electron shell. If a K atom is stripped of its outer-shell electron, it becomes the *positive ion* K^+ with the electron configuration [Ar]. A Ca atom acquires the [Ar] configuration following the removal of two electrons.

$$\mathrm{K}([\mathrm{Ar}]4s^1) \longrightarrow \mathrm{K}^+([\mathrm{Ar}]) + e^-$$
$$\mathrm{Ca}([\mathrm{Ar}]4s^2) \longrightarrow \mathrm{Ca}^{2+}([\mathrm{Ar}]) + 2\,e^-$$



▲ Metals tend to lose electrons to attain noble gas electron configurations.

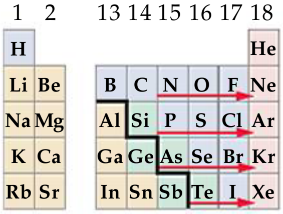
Although metal atoms do not lose electrons spontaneously, the energy required to bring about ionization is often provided by other processes occurring at the same time (such as an attraction between positive and negative ions). Aluminum is the only *p*-block metal that forms an ion with a noble gas electron configuration—Al^{3+}. This is because all other *p*-block elements would have to remove 10 *d* electrons to attain the electron configuration of the previous noble gas. The electron configurations of the other *p*-block metal ions are summarized in Table 9.2.

TABLE 9.2 Electron Configurations of Some Metal Ions[a]

“Noble Gas”		“Pseudo-Noble Gas”[b]	“18 + 2”[c]	Other
Li^+	Be^{2+}	Ga^{3+}	In^+	Cr^{2+}, Cr^{3+}
Na^+	Mg^{2+}	Tl^{3+}	Tl^+	Mn^{2+}, Fe^{2+}
K^+	Ca^{2+}	Cu^+	Sn^{2+}	Fe^{3+}, Co^{2+}
Rb^+	Sr^{2+}	Ag^+, Au^+	Pb^{2+}	Ni^{2+}, Cu^{2+}
Cs^+	Ba^{2+}	Zn^{2+}	Sb^{3+}	
Fr^+	Ra^{2+}		Bi^{3+}	
Al^{3+}				

[a] Main-group metal ions are printed in black and transition metal ions in blue.
[b] In the configuration labeled “pseudo-noble gas,” all electrons of the outermost shell have been lost. The next-to-outermost electron shell of the atom becomes the outermost shell of the ion and contains 18 electrons, for example, Ga^{3+}: $[Ne]3s^23p^63d^{10}$.
[c] In the configuration labeled “18 + 2” all outer-shell electrons except the two *s* electrons are lost, producing an ion with 18 electrons in the next-to-outermost shell and 2 electrons in the outermost, for example, Sn^{2+}: $[Ar]3d^{10}4s^24p^64d^{10}5s^2$.

Main-Group Nonmetal Ions



▲ Nonmetals tend to gain electrons to attain noble-gas electron configurations.

The atoms of groups 17 and 16—the most active nonmetals—have one and two electrons fewer than the noble gas at the end of the period. Groups 17 and 16 atoms can acquire the electron configurations of noble gas atoms by *gaining* the appropriate numbers of electrons.

$$Cl([Ne]3s^23p^5) + e^- \longrightarrow Cl^-([Ar])$$
$$S([Ne]3s^23p^4) + 2\,e^- \longrightarrow S^{2-}([Ar])$$

In most cases, a nonmetal atom will gain a single electron spontaneously, but energy is required to force it to accept more than one. The necessary energy is often supplied by other processes that occur simultaneously (such as an attraction between positive and negative ions). Nonmetal ions with a charge of 3− are rare. However, some metal nitrides containing the nitride ion, N^{3-}, and some metal phosphides containing the phosphide ion, P^{3-}, are known.

Transition Metal Ions

In the aufbau process, the *ns* subshell fills before electrons enter the $(n-1)d$ subshell (page 340), but the energy levels of these two subshells are nearly the same (Fig. 8-36). Thus, it is not surprising that when transition metal atoms ionize, the *ns* subshell is emptied. For example, the electron configuration of Ti is $[Ar]3d^24s^2$, and that of Ti^{2+} is $[Ar]3d^2$. Moreover, in some cases one or more $(n-1)d$ electrons might be lost together with the *ns* electrons. This happens in the formation of Ti^{4+}, which has the electron configuration [Ar].

A few transition metal atoms acquire noble-gas electron configurations when forming cations, as do Sc in Sc^{3+} and Ti in Ti^{4+}, but most transition metal atoms do not (see Table 9.2). An iron atom does not acquire a noble-gas electron configuration when it loses its $4s^2$ electrons to form the ion Fe^{2+},

$$Fe([Ar]3d^64s^2) \longrightarrow Fe^{2+}([Ar]3d^6) + 2\,e^-$$

nor does it with the loss of an additional 3*d* electron to form the ion Fe^{3+}.

$$Fe([Ar]3d^64s^2) \longrightarrow Fe^{3+}([Ar]3d^5) + 3\,e^-$$

The 3*d* subshell in Fe^{3+} is half-filled, a fact that helps to account for the observed ease of oxidation of iron(II) to iron(III) compounds. Electron configurations with half-filled or filled *d* or *f* subshells have a special stability, and a number of transition metal ions have such configurations.

▶ A useful mnemonic is that the electron configuration of a cation can be obtained from the electron configuration of the parent atom by removing those electrons in orbitals with the *highest* quantum number first.

Hydrogen

Although all the other elements have a definite place in the periodic table, hydrogen does not. Its uniqueness stems from the fact that its atoms have only one electron, in the configuration $1s^1$. This single electron is the reason that we put hydrogen in group 1, even though we classify it as a nonmetal. Hydrogen does appear to become metallic when subjected to pressures of about 2 million bar, but these are hardly ordinary laboratory conditions. Because hydrogen, like the halogens, is one electron short of having a noble-gas electron configuration, it is sometimes placed in group 17; however, hydrogen does not resemble the halogens very much. For example, F_2 and Cl_2 are excellent oxidizing agents, but H_2 is a reducing agent. Still another alternative places hydrogen by itself at the top of the periodic table and near the center.

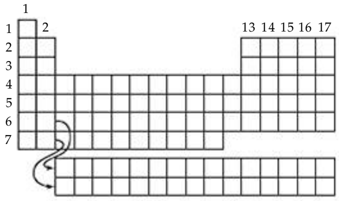
9-1 CONCEPT ASSESSMENT

On the blank periodic table in the margin, indicate where elements that satisfy the following descriptions occur.

(a) A noble gas having the same electron configuration as the Na^+ cation

(b) An anion of a nonmetal with a charge of 3− that has a noble-gas electron configuration

(c) A transition metal ion with a charge of 2+ and no valence shell *s* and *p* electrons



9-3 Sizes of Atoms and Ions

In earlier chapters we discovered the importance of atomic masses in matters relating to stoichiometry. To understand certain physical and chemical properties, we need to know something about atomic sizes. In this section we describe atomic radius, the first of a group of atomic properties that we will examine in this chapter.

Atomic Radius

Unfortunately, atomic radius is hard to define. The probability of finding an electron decreases with increasing distance from the nucleus, but nowhere does the probability fall to zero, so there is no precise outer boundary to an atom. We might describe an *effective* atomic radius as, say, the distance from the nucleus within which 95% of all the electron charge density is found, but in fact, all that we can measure is the distance between the nuclei of adjacent atoms (internuclear distance). Even though it varies, depending on whether atoms are chemically bonded or merely in contact without forming a bond, we define atomic radius in terms of internuclear distance.

Because we are primarily interested in bonded atoms, we will emphasize an atomic radius based on the distance between the nuclei of two atoms joined by a chemical bond. The **covalent radius** is one-half the distance between the nuclei of two identical atoms joined by a single covalent bond. The **ionic radius** is based on the distance between the nuclei of ions joined by an ionic bond. Because the ions are not identical in size, this distance must be properly apportioned between the cation and anion. One way to apportion the electron density between the ions is to define the radius of one ion and then infer the radius of the other ion. The convention we have chosen to use is to assign O^{2-} an ionic radius of 140 pm. An alternative apportioning scheme is to use F^- as the reference ionic radius. When using ionic radii data, one should carefully note which convention is used and not mix radii from the different conventions. Starting with a radius of 140 pm for O^{2-}, the radius of Mg^{2+} can be obtained from the internuclear distance in MgO, the radius of Cl^- from the internuclear distance in $MgCl_2$, and the radius of Na^+ from the internuclear distance in NaCl. For metals, we define a **metallic radius** as one-half the distance between the nuclei of two atoms in contact in the crystalline solid metal. Similarly in a solid sample of a noble gas the distance between the centers of neighboring atoms is called the **van der Waals radius**. There is much debate about the values of the atomic radii of noble gases because the experimental determination of the van der Waals radii is difficult; consequently, the atomic radii of noble gases are left out of the discussion of trends in atomic radii.

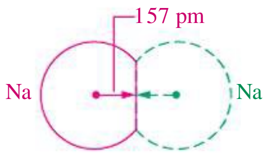
The angstrom unit, Å, has long been used for atomic dimensions ($1\text{ Å} = 10^{-10}\text{ m}$). The angstrom, however, is not a recognized SI unit. The SI units are the nanometer (nm) and picometer (pm).

$$1\text{ nm} = 1 \times 10^{-9}\text{ m}; 1\text{ pm} = 1 \times 10^{-12}\text{ m}; 1\text{ nm} = 1000\text{ pm} \qquad \textbf{(9.2)}$$

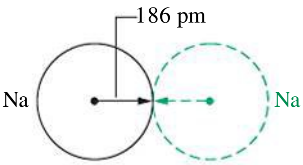
▶ Despite the SI convention, the angstrom unit, Å, is still widely used by X-ray crystallographers and others who work with atomic and molecular dimensions.

Figure 9-3 illustrates the definitions of covalent, ionic, and metallic radii by comparing these three radii for sodium. Figure 9-4 is a plot of atomic radius against atomic number for a large number of elements. In this plot metallic radii are used for metals and covalent radii for nonmetals. Figure 9-4 suggests certain trends in atomic radii, for example, large radii for group 1, decreasing across the periods to smaller radii for group 17. To interpret these trends, let us first return to a topic introduced in Chapter 8.

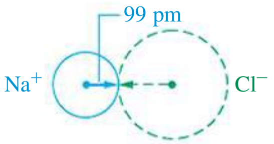
Covalent radius:



Metallic radius:



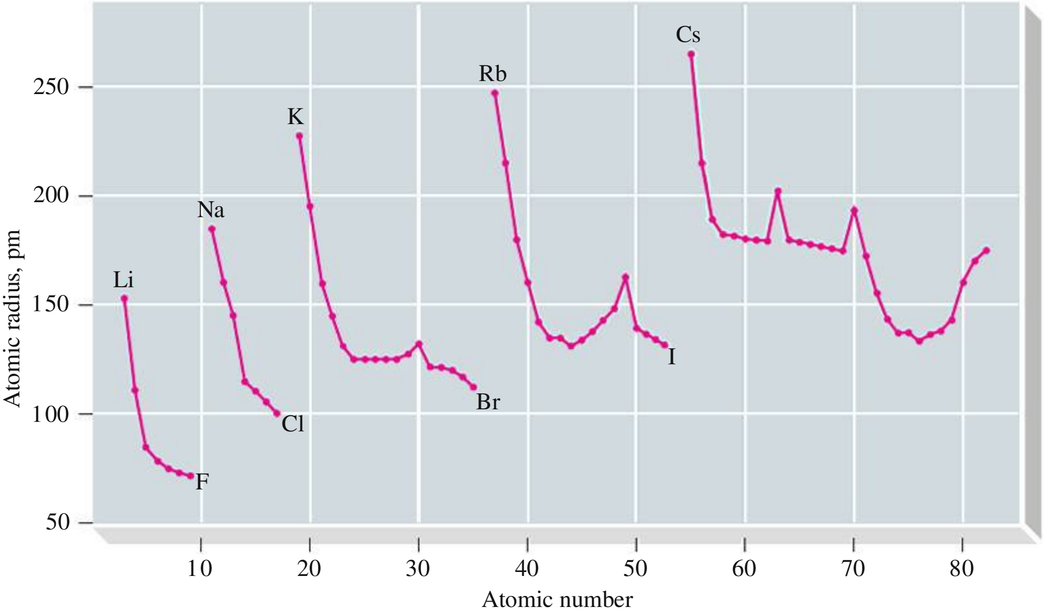
Ionic radius:



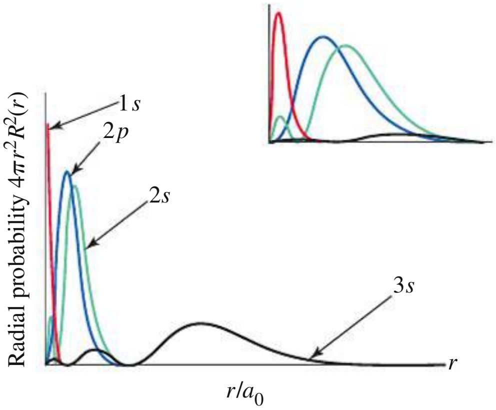
▲ FIGURE 9-3
Covalent, metallic, and ionic radii compared
Atomic radii are represented by the solid arrows. The covalent radius is based on the diatomic molecule $Na_2(g)$, found only in gaseous sodium. The metallic radius is based on adjacent atoms in solid sodium, Na(s). The value of the ionic radius of Na^+ is obtained by the comparative method described in the text.

Screening and Penetration

In Section 8-10, penetration was described as a gauge of how close an electron gets to the nucleus. When interpreting the radial probability distributions, we saw that *s* electrons, by virtue of their extra humps of probability close to the nucleus (Fig. 8-35), penetrate better than *p* electrons, which in turn penetrate better than *d* electrons. Screening, or shielding, reflects how an outer electron is blocked from the nuclear charge by inner electrons.



▲ FIGURE 9-4
Atomic radii
The values plotted are metallic radii for metals and covalent radii for nonmetals. Data for the noble gases are not included because of the difficulty of measuring covalent radii for these elements (only Kr and Xe compounds are known). The explanations usually given for the several small peaks in the middle of some periods are beyond the scope of this discussion.



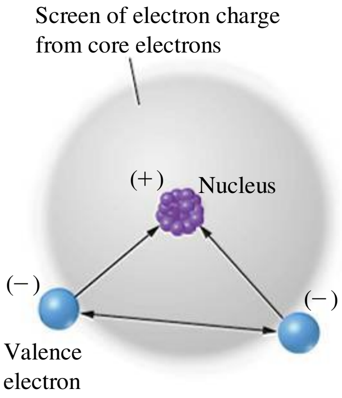
◀ FIGURE 9-5
Radial probability distributions for magnesium
Graphs of $4\pi r^2R^2(r)$ as a function of r for the 1s, 2s, and 3s orbitals of magnesium. The graphs were obtained by using the radial functions from Table 8.1 with $Z_{\text{eff}} = 11.61$ (for 1s); $Z_{\text{eff}} = 7.39$ (for 2s); $Z_{\text{eff}} = 7.83$ (for 2p); and $Z_{\text{eff}} = 3.31$ (for 3s). The inset plot has a smaller range of r values in order to highlight the behavior of the probability functions closer to $r = 0$.

Consider the hypothetical process of building up each atom in the third period from the atom preceding it, beginning with sodium. In this process, the number of inner-shell, or core, electrons is fixed at ten in the configuration $1s^22s^22p^6$. As a first approximation, let us *assume* that the core electrons completely cancel an equivalent charge on the nucleus. In this way, the core electrons shield, or screen, the outer-shell electrons from the full attractive force of the nucleus. Let us also assume that the outer-shell electrons do not screen one another. Finally, let us redefine an **effective nuclear charge**, Z_{eff}, first introduced in Section 8-10, as the true nuclear charge minus the charge that is screened out by electrons.

$$Z_{\text{eff}} = Z - S \tag{9.3}$$

Think of S as representing the number of inner electrons that appear to screen or shield an outer electron. Based on the two assumptions just stated, in sodium $(Z = 11)$ the ten core electrons would screen out 10 units of nuclear charge (that is, $S = 10$), leaving an effective nuclear charge of $11 - 10 = +1$. In magnesium $(Z = 12)$, Z_{eff} would be +2. In aluminum, Z_{eff} would be +3, and so on across the period.

Actually, neither assumption we made above—full screening by inner-shell electrons and no screening by outer-shell electrons—is correct. These assumptions ignore the fact that the electrons, both inner and outer, occupy orbitals with different radial probability distributions and, consequently, different degrees of penetration (Fig. 9-5). Thus, an *s* electron, with its greater penetration, will be screened by inner electrons less than will a *p* electron. Similarly a *p* electron is shielded less than a *d* electron, which has a much lower penetration. In sodium, the 10 core electrons cancel only about 8.5 units of charge; thus, Z_{eff} is about 2.5+, not 1+. Also, outer-shell electrons do screen one another somewhat because of penetration effects. Each outer-shell electron is about one-third effective in screening the other outer-shell electrons. Thus, the Z_{eff} experienced by each of the two outer-shell electrons in magnesium is about $12 - 8.5 - \frac{1}{3} = 3.2+$, not 2+ (Fig. 9-6). As we will see, trends in properties of atoms and ions in the periodic table are largely governed by the effective nuclear charge, Z_{eff}.



▲ FIGURE 9-6
The shielding effect and effective nuclear charge, Z_{eff}
Two valence electrons (blue) are attracted to the nucleus of a Mg atom. The atom's 12+ nuclear charge is screened by the 10 core electrons (gray), but not perfectly. The valence electrons also screen each other somewhat. The result is an *effective* nuclear charge, Z_{eff}, closer to 3+ than to 2+.

The Effects of Penetration and Screening The wave function of a multielectron atom provides a qualitative understanding of the effects of penetration and screening. In this simplified picture, the nuclear charge is replaced by Z_{eff}, so that the orbital energy is approximated by

$$E_n = -R_{\text{H}}\frac{Z_{\text{eff}}^2}{n^2} \tag{9.4}$$

where Z_{eff} is the effective nuclear charge in the shell corresponding to the value of n. All other symbols have their usual meaning (see Chapter 8). Equation (9.4) has the same form as the energy of the hydrogen atom obtained as a solution to the Schrödinger equation. The multielectron atom has been reduced to a one-electron approximation, a great oversimplification, but useful nevertheless. The average size of an orbital is taken to be the average value of the distance, $\bar{r}_{nl}$, of the electron in that orbital from the nucleus.

$$\bar{r}_{nl} = \frac{n^2 a_0}{Z_{\text{eff}}}\left\{1 + \frac{1}{2}\left[1 - \frac{\ell(\ell + 1)}{n^2}\right]\right\} \tag{9.5}$$

▶ The leading term of equation (9.5) is the Bohr radius of the nth Bohr orbit. The corresponding formula for the orbitals of the H atom can be obtained by setting $Z_{\text{eff}} = 1$.

9-1 ARE YOU WONDERING...

Where estimates of the screening by electrons come from?

These estimates come from an analysis of the wave functions of multielectron atoms. An exact solution of the Schrödinger equation can be obtained for the H atom, but for multielectron atoms, only approximate solutions are possible. The principle of the calculation is to assume each electron in the atom occupies an orbital much like those of the hydrogen atom. However, the functional form of the orbital is based on another assumption: that the electron moves in an effective or average field dictated by all the other electrons. With this assumption, the complicated multielectron Schrödinger equation is converted into a set of simultaneous equations—one for each electron. Each equation contains the unknown effective field and the unknown functional form of the orbital for the electron. The approach to solving such a set of equations is to guess at the functional forms of the orbitals, calculate an average potential for each electron to move in, and then solve for a new set of orbitals—one for each electron. The expectation is that the new orbitals are better than the initial guess. The new orbitals are then used to calculate a new effective field for the electrons, and the whole process is repeated until the calculated orbitals do not change much.

This iterative procedure, called the *self-consistent field* (*SCF*) *method*, was devised by Douglas Hartree in 1936, before the advent of computers. Currently, the wave functions of atoms and molecules are obtained by implementing the SCF procedures on computers. The use of computers to calculate molecular properties from a wave function by the SCF procedure has lead to the term molecular modeling. Molecular modeling has become a tool in modern chemical research.

The atomic orbitals obtained from SCF calculations closely resemble the atomic orbitals of the hydrogen atom in many ways. The angular dependence of the orbitals is identical, so that we can identify s, p, d, f orbitals by their characteristic shapes. The radial functions of the orbitals are different because the effective field is different from the one in the hydrogen atom, but the principal quantum number can still be defined. Thus, each electron in a multielectron atom has associated with it the four quantum numbers n, ℓ, m_ℓ, and m_s. Estimates of screening constants are based on an analysis of the radial functions obtained from SCF calculations.

In equation (9.5), all the symbols have their usual meaning. Again, equation (9.5) is the equation for the hydrogen atom or hydrogen-like ions with the nuclear charge replaced by Z_{eff} to approximate multielectron effects. Equations (9.4) and (9.5) are approximate but provide for a very useful semiquantitative interpretation of atomic properties. We consider next the three most important trends among atomic radii in relation to the periodic table.

KEEP IN MIND

that s- and p-valence electrons have some probability of being near the nucleus (Fig. 8-35). These electrons penetrate the inner core of electrons and experience a greater attraction to the nucleus than otherwise expected.

1. **Variation of Atomic Radii Within a Group of the Periodic Table.** Radial probability densities extend farther out from the nucleus as n increases, a fact seen both in Figure 8-35 and in equation (9.5). Thus, we should expect that the more electron shells occupied by electrons, the larger the atom. This idea works for the group members of lower atomic numbers, where the increase in radius from one period to the next is large (as from Li to Na to K in group 1). At higher atomic numbers, the increase in radius is smaller (as from K to Rb to Cs in group 1). In these elements of higher atomic number, outer-shell electrons are held somewhat more tightly than

expected because inner-shell electrons in *d* and *f* subshells are less effective than *s* and *p* electrons in screening outer-shell electrons from the nucleus; that is, Z_{eff} is larger than expected. Nevertheless, in general, the following is true.

The more electronic shells in an atom, the larger is the atom. Atomic radius increases from top to bottom through a group of elements.

2. **Variation of Atomic Radii Within a Period of the Periodic Table.** From Figure 9-4, we see that, in general, atomic radius decreases from left to right across a period. A careful look at the figure suggests that this trend does not apply to the transition elements. Let us look first at the general trend of decreasing radii and then at what is special about the transition elements.

   Across a period, the atomic number increases by one for each succeeding element. For the main-group elements, each increase in atomic number is accompanied by the addition of one electron to the valence shell. The valence-shell electrons, being in the same shell, shield each other poorly from the increasing nuclear charge. The Z_{eff} for the 2*s* electron of Li is 1.3, and that for Be is 1.9; thus, Z_{eff} increases as Z increases across the main-group portions of a period. Across a period, the principal quantum number stays constant, so that whether we use Z_{eff} or just the nuclear charge Z in equation (9.5), the result is as follows.

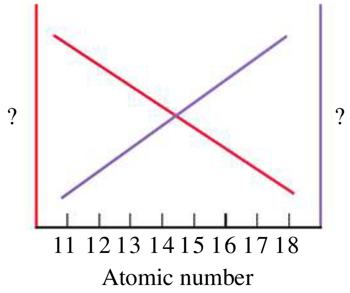
◀ Values of Z_{eff} can be estimated using the rules set out in Feature Problem 73.

The atomic radius decreases from left to right through a period of elements.

3. **Variation in Atomic Radius Within a Transition Series.** With the transition elements, the situation is a little different from that described above. In Figure 9-4, it is apparent that the atomic radii of transition elements tend to be about the same across a period but with a few unusual peaks. It is beyond the scope of this text to explain the exceptions; however, the general trend is not difficult to understand. In a series of transition elements, additional electrons go into an *inner* electron shell, where they participate in shielding outer-shell electrons from the nucleus. At the same time, the number of electrons in the *outer* shell tends to remain constant. Thus, the outer-shell electrons experience a roughly comparable force of attraction to the nucleus throughout a transition series. Consider Fe, Co, and Ni. Fe has 26 protons in the nucleus and 24 inner-shell electrons. In Co $(Z = 27)$, there are 25 inner-shell electrons, and in Ni $(Z = 28)$, there are 26. In each case, the two outer-shell electrons are under the influence of about the same net charge (about +2). That is, Z_{eff} for the 4*s* electrons of the first transition series is approximately constant. Thus, atomic radii do not change very much for this series of three elements, namely, 124 pm for Fe and 125 pm for Co and Ni.

9-2 CONCEPT ASSESSMENT

The graph in the margin represents the variation of Z_{eff} and atomic radius with atomic number. Which axis and correspondingly colored line corresponds to Z_{eff} and which to atomic radius?



EXAMPLE 9-1 Relating Atomic Size to Position in the Periodic Table

Refer only to the periodic table on the inside front cover, and determine which is the largest atom: Sc, Ba, or Se.

Analyze

We first place the element in the periodic table and decide whether or not the elements are in the same period and whether they are on the right or left of the periodic table. We can then use the rules noted above to decide on the relative sizes of atoms (or ions).

Solve

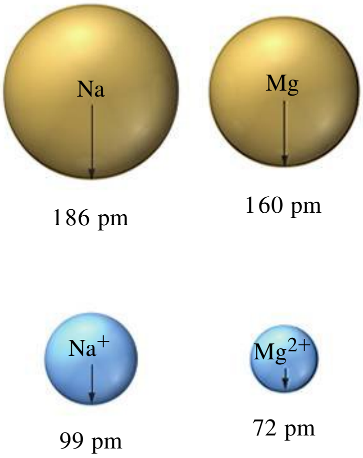
Sc and Se are both in the fourth period, and we would expect Sc to be larger than Se because atomic sizes decrease from left to right in a period. Ba is in the sixth period and so has more electronic shells than either Sc or Se. Furthermore, it lies even closer to the left side of the table (group 2) than does Sc (group 3). We can say with confidence that the Ba atom should be the largest of the three.

Assess

By using the procedure outlined above, we have been able to show that $r_{\text{Ba}} > r_{\text{Sc}} > r_{\text{Se}}$. The actual atomic radii are Se, 117 pm; Sc, 161 pm; and Ba, 217 pm.

PRACTICE EXAMPLE A: Use the periodic table on the inside front cover to predict which is the smallest atom: As, I, or S.

PRACTICE EXAMPLE B: Which of the following atoms do you think is closest in size to the Na atom: Br, Ca, K, or Al? Explain your reasoning, and do not use any tabulated data from the chapter in reaching your conclusion.



▲ FIGURE 9-7
A comparison of atomic and ionic sizes
Metallic radii are shown for Na and Mg and ionic radii for Na^+ and Mg^{2+}.

Ionic Radius

When a metal atom loses one or more electrons to form a positive ion, the positive nuclear charge exceeds the negative charge of the electrons in the resulting cation. The nucleus draws the electrons in closer, and, as a consequence, the following holds true.

Cations are smaller than the atoms from which they are formed.

Figure 9-7 compares four species: the atoms Na and Mg and the ions Na^+ and Mg^{2+}. As expected, the Mg atom is smaller than the Na atom, and the cations are smaller than the corresponding atoms. Na^+ and Mg^{2+} are **isoelectronic**—they have equal numbers of electrons (10) in identical configurations, $1s^22s^22p^6$. Mg^{2+} is smaller than Na^+ because its nuclear charge is larger (+12, compared with +11 for Na).

For isoelectronic cations, the more positive the ionic charge, the smaller the ionic radius.

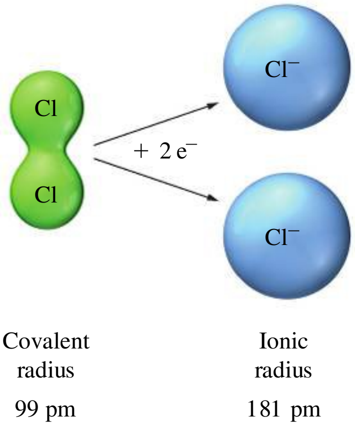
When a nonmetal atom gains one or more electrons to form a negative ion (anion), the nuclear charge remains constant, but Z_{eff} is reduced because of the additional electron(s). The electrons are not held as tightly. Repulsions among the electrons increase. The electrons spread out more, and the size of the atom increases, as suggested in Figure 9-8.

Anions are larger than the atoms from which they are formed. For isoelectronic anions, the more negative the charge, the larger the ionic radius.

Knowledge of atomic and ionic radii can be used to vary certain physical properties. One example concerns strengthening glass. Normal window glass contains Na^+ and Ca^{2+} ions. The glass is brittle and shatters easily when struck a hard blow. One way to strengthen the glass is to replace the Na^+ ions at the surface with K^+ ions. The K^+ ions are larger and fill up the surface sites, leaving less opportunity for cracking than with the smaller Na^+ ions. The result is a shatter-resistant glass.

Another example is the striking result when Cr^{3+} ions replace about 1% of the Al^{3+} ions in aluminum oxide, Al_2O_3. This substitution is possible because Cr^{3+} ions are only slightly larger (by 9 pm) than Al^{3+} ions. Pure aluminum oxide is colorless, but with this small amount of chromium(III) ion, it is a beautiful red color. This impure Al_2O_3 is the gem known as a ruby. Rubies and other gemstones can be made artificially and are used as jewelry and in devices such as lasers. The color of the ruby is further discussed in Chapter 24.

Figure 9-9, arranged in the format of the periodic table, shows relative sizes of typical atoms and ions, and summarizes the generalizations described in this section.



▲ FIGURE 9-8
Covalent and anionic radii compared
The two Cl atoms in a Cl_2 molecule gain one electron each to form two Cl^- ions.

EXAMPLE 9-2 Comparing the Sizes of Cations and Anions

Refer only to the periodic table on the inside front cover, and arrange the following species in order of increasing size: K^+, Cl^-, S^{2-}, and Ca^{2+}.

Analyze

The key lies in recognizing that the four species are *isoelectronic*, having the electron configuration of argon: $1s^22s^22p^63s^23p^6$. When considering isoelectronic cations, the higher the charge on the ion, the smaller the ion.

Solve

The larger charge on the calcium ion means that Ca^{2+} is smaller than K^+. Because K^+ has a higher nuclear charge than Cl^- ($Z = 19$, compared with $Z = 17$), it is smaller than Cl^-. For isoelectronic anions, the higher the charge, the larger the ion. S^{2-} is larger than Cl^-. The order of increasing size is

$$Ca^{2+} < K^+ < Cl^- < S^{2-}$$

Assess

We can summarize the generalizations about isoelectronic atoms and ions into a single statement: Among isoelectronic species, the greater the atomic number, the smaller the size.

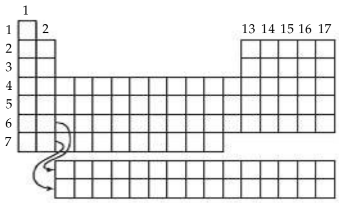
PRACTICE EXAMPLE A: Refer only to the periodic table on the inside front cover, and arrange the following species in order of increasing size: Ti^{2+}, V^{3+}, Ca^{2+}, Br^-, and Sr^{2+}.

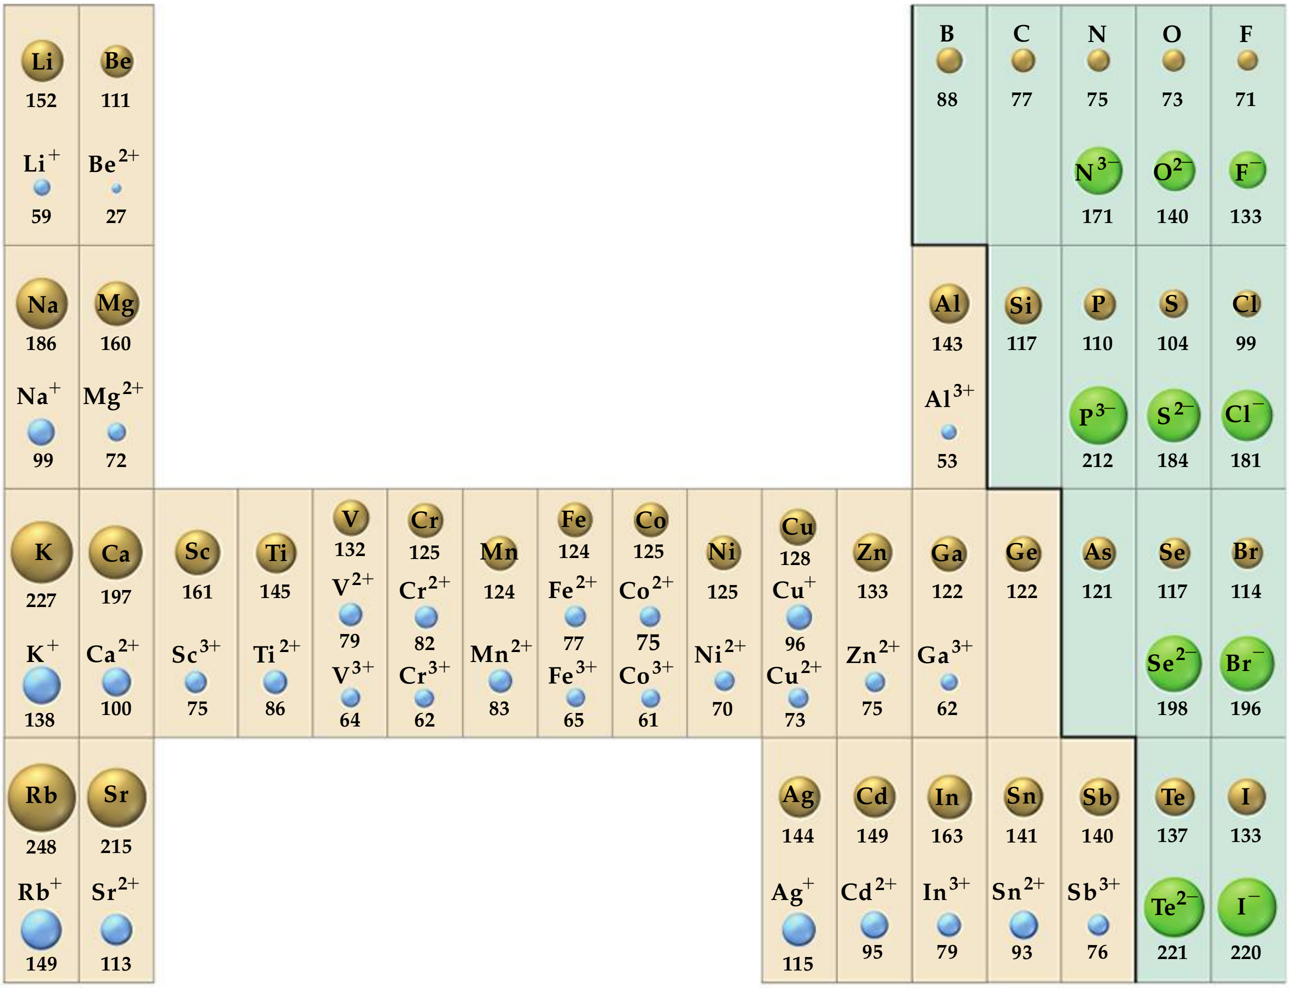
PRACTICE EXAMPLE B: Refer only to the periodic table on the inside front cover, and determine which species is in the *middle* position when the following five are ranked according to size: the atoms N, Cs, and As and the ions Mg^{2+} and Br^-.

9-3 CONCEPT ASSESSMENT

On the blank periodic table in the margin, locate the following:

(a) The smallest group 13 atom
(b) The smallest period 3 atom
(c) The largest anion of a nonmetal in period 3
(d) The largest group 13 cation





▲ FIGURE 9-9
A comparison of some atomic and ionic radii
The values given, in picometers (pm), are metallic radii for metals, single covalent radii for nonmetals, and ionic radii for the ions indicated.

9-4 Ionization Energy

In discussing metals, we talked about metal atoms losing electrons and thereby altering their electron configurations. But atoms do not eject electrons spontaneously. Electrons are attracted to the positive charge on the nucleus of an atom, and energy is needed to overcome that attraction. The more easily its electrons are lost, the more metallic an atom is considered to be. The **ionization energy**, ***I***, is the quantity of energy a *gaseous* atom must absorb to be able to expel an electron. The electron that is lost is the one that is most loosely held.

Ionization energies are usually measured through experiments based on the photoelectric effect in which gaseous atoms at low pressures are bombarded with photons of sufficient energy to eject an electron from the atom. Here are two typical values.

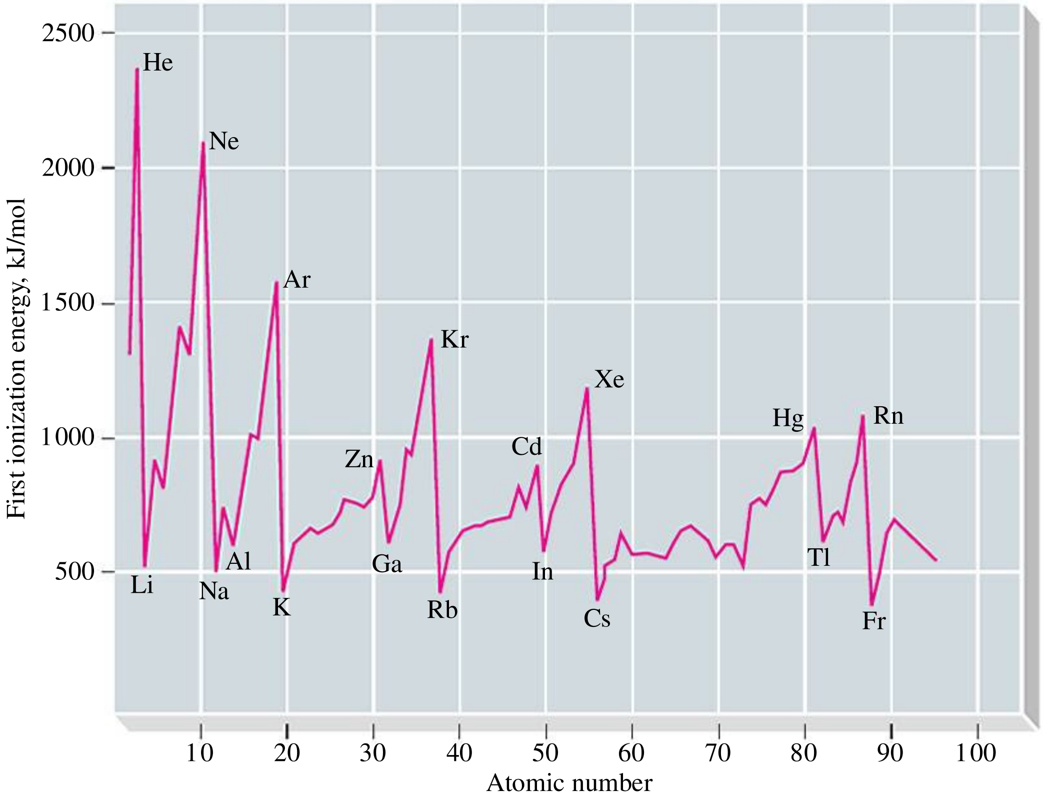
$$\mathrm{Mg(g)} \longrightarrow \mathrm{Mg^+(g)} + e^- \qquad I_1 = 738\ \mathrm{kJ/mol}$$
$$\mathrm{Mg^+(g)} \longrightarrow \mathrm{Mg^{2+}(g)} + e^- \qquad I_2 = 1451\ \mathrm{kJ/mol}$$

The symbol I_1 stands for the *first* ionization energy—the energy required to strip one electron from a neutral gaseous atom.* I_2 is the *second* ionization energy—the energy to strip an electron from a gaseous ion with a charge of 1+. Further ionization energies are I_3, I_4, and so on. Each succeeding ionization energy is invariably larger than the preceding one. In the case of magnesium, for example, in the second ionization, the electron, once freed, has to move away from an ion with a charge of 2+ (Mg^{2+}). More energy must be invested than for a freed electron to move away from an ion with a charge of 1+ (Mg^{+}). This is a direct consequence of Coulomb's law, which states, in part, that the force of attraction between oppositely charged particles is directly proportional to the magnitudes of the charges.

◀ A distinction between valence electrons and core electrons can be made based on the ionization energies for removing electrons one by one. The ionization energies of valence electrons are much smaller and show a big jump when the first core electron is removed.

First ionization energies (I_1) for many of the elements are plotted in Figure 9-10. In general, the farther an electron is from the nucleus, the more easily it can be extracted.

Ionization energies decrease as atomic radii increase.



▲ FIGURE 9-10

First ionization energies as a function of atomic number

Because their electron configurations are so stable, more energy is required to ionize noble gas atoms than to ionize atoms of the elements immediately preceding or following them. The maxima on the graph come at the atomic numbers of the noble gases. The alkali metals are the most easily ionized of all groups. The minima in the graph come at their atomic numbers.

---

*Ionization energies are sometimes expressed in the unit electron-volt (eV). One electron-volt is the energy acquired by an electron as it falls through an electric potential difference of 1 volt. It is a very small energy unit, especially suited to describing processes involving individual atoms. When ionization is based on a *mole* of atoms, kJ/mol is the preferred unit (1 eV/atom = 96.49 kJ/mol). Sometimes the term *ionization potential* is used instead of ionization energy. Further, the quantities $I_1, I_2, \ldots,$ may be replaced by enthalpy changes, ΔH_1, ΔH_2, and so on.

▶ This generalization works well for main-group elements but less so for transition elements, where there are several exceptions.

This observation that ionization energies decrease as atomic radii increase reflects the effect of n and Z_{eff} on the ionization energy (I). Equation (9.4) suggests that the ionization energy is given by

$$I = R_{\text{H}} \times \frac{Z_{\text{eff}}^2}{n^2} \qquad (9.6)$$

so that across a period, as Z_{eff} increases and the valence-shell principal quantum number n remains constant, the ionization energy should increase. And down a group, as n increases and Z_{eff} increases only slightly, the ionization energy should decrease. Thus, atoms lose electrons more easily (become more metallic) as we move from top to bottom in a group of the periodic table. The decreases in ionization energy and the parallel increases in atomic radii are outlined in Table 9.3 for group 1.

TABLE 9.3 Atomic Radii and First Ionization Energies of the Alkali Metal (Group 1) Elements

	Atomic Radius, pm	Ionization Energy (I_1), kJ/mol
Li	152	520.2
Na	186	495.8
K	227	418.8
Rb	248	403.0
Cs	265	375.7

Table 9.4 lists ionization energies for the third-period elements. With minor exceptions, the trend in moving across a period (follow the colored stripe) is that atomic radii decrease, ionization energies increase, and the elements become less metallic, or more nonmetallic, in character. Table 9.4 lists stepwise ionization energies (I_1, I_2, and so forth.). Note particularly the large breaks that occur along the zigzag diagonal line. Consider magnesium as an example. To remove a third electron, as measured by I_3, requires breaking into the especially stable noble-gas inner-shell electron configuration $2s^22p^6$. I_3 is *much* larger than I_2—so much larger that Mg^{3+} cannot be produced in ordinary chemical processes. Similarly, we do not encounter the ions Na^{2+} or Al^{4+} in chemical processes.

Now let us turn to the obvious exceptions to the regular trend in I_1 values for the third-period elements and ask, Why is I_1 of Al smaller than that of Mg and I_1 of S smaller than that of P?

TABLE 9.4 Ionization Energies of the Third-Period Elements (in kJ/mol)

	Na	Mg	Al	Si	P	S	Cl	Ar
I_1	495.8	737.7	577.6	786.5	1,012	999.6	1,251.1	1,520.5
I_2	4,562	1,451	1,817	1,577	1,903	2,251	2,297	2,666
I_3		7,733	2,745	3,232	2,912	3,361	3,822	3,931
I_4			11,580	4,356	4,957	4,564	5,158	5,771
I_5				16,090	6,274	7,013	6,542	7,238
I_6					21,270	8,496	9,362	8,781
I_7						27,110	11,020	12,000

9-2 ARE YOU WONDERING...

If ionization energies can be used to estimate the effective nuclear charge?

One of the earliest estimates of effective nuclear charge was obtained by analyzing ionization energies in terms of equation (9.6). Thus, for example, the ionization energy of Li in its ground state is 519 kJ mol^{-1} and from equation (9.6), we have

$$I_1 = 1312.1\frac{Z_{\text{eff}}^2}{n^2}\,\text{kJ mol}^{-1}$$

so that

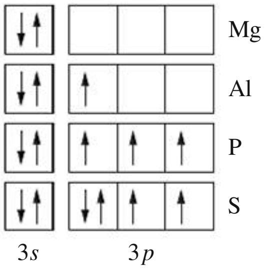
$$519\,\text{kJ}\,\text{mol}^{-1} = 1312.1\frac{Z_{\text{eff}}^2}{2^2}\,\text{kJ}\,\text{mol}^{-1}$$

and we get

$$Z_{\text{eff}} = 1.26$$

The Z_{eff} obtained from the ionization energy of the first excited state of Li$(1s^2 2p)$, 339 kJ mol^{-1}, is 1.02. The value of Z_{eff} is very close to one because the inner $1s^2$ core almost perfectly screens the $2p$ electron. By contrast, the penetration of the $2s$ electron leads to the somewhat larger $Z_{\text{eff}} = 1.26$ for the ground state.

Consider the orbital diagrams for Mg, Al, P, and S shown in the margin. We expect I_1 of Al to be larger than for Mg. The reversal occurs because of the particular electrons lost. Mg loses a $3s$ electron, while Al loses a $3p$ electron. We expect that *more* energy is required to strip an electron from the lower energy $3s$ orbital in Mg $([\text{Ne}]3s^2)$ than from a half-filled $3p$ orbital in Al $([\text{Ne}]3s^2 3p^1)$. I_1 for S is slightly lower than for P for a different reason. Although the orbitals in the $3p$ subshell are degenerate, we can think of repulsion between electrons in the filled $3p$ orbital of a S atom $([\text{Ne}]3s^2 3p^4)$ as making it easier to remove one of those electrons than an electron from the half-filled $3p$ subshell of a P atom $([\text{Ne}]3s^2 3p^3)$.



▲ Orbital diagram showing the valence electron configuration of magnesium, aluminum, phosphorus, and sulfur.

EXAMPLE 9-3 Relating Ionization Energies

Refer to the periodic table on the inside front cover, and arrange the following in the expected order of increasing first ionization energy, I_1: As, Sn, Br, Sr.

Analyze

Ionization energies decrease as atomic radii increase. Thus, if we arrange these four atoms according to decreasing radius, we will likely have arranged them according to increasing ionization energy. The largest atoms are to the left and the bottom of the periodic table. The smallest atoms are to the right and toward the top of the periodic table.

Solve

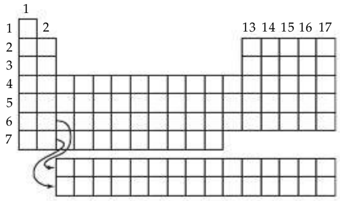
Of the four atoms, the one that best fits the large-atom category is Sr. Although none of the four atoms is particularly close to the top of the table, Br is the farthest to the right. This fixes the two extremes: Sr with the lowest ionization energy and Br with the highest. A tin atom should be larger than an arsenic atom, and thus Sn should have a lower ionization energy than As. The expected order of *increasing* ionization energies is $\text{Sr} < \text{Sn} < \text{As} < \text{Br}$.

Assess

The generalization that ionization energies decrease as atomic radii increase ignores the exceptions that occur when making comparisons between atoms of groups 2 and 13, as well as atoms of groups 15 and 16.

PRACTICE EXAMPLE A: Refer to the periodic table on the inside front cover, and arrange the following in the expected order of increasing first ionization energy, I_1: Cl, K, Mg, S.

PRACTICE EXAMPLE B: Refer to the periodic table on the inside front cover, and determine which element is most likely in the *middle* position when the following five elements are arranged according to first ionization energy, I_1. Rb, As, Sb, Br, Sr.



9-4 CONCEPT ASSESSMENT

On the blank periodic table in the margin, locate the following:

(a) The group 14 element with the highest first ionization energy

(b) The element with the greatest first ionization energy in period 4

(c) A *p*-block element in period 4 that has a lower first ionization energy than the element immediately preceding it and the element directly following it

9-5 Electron Affinity

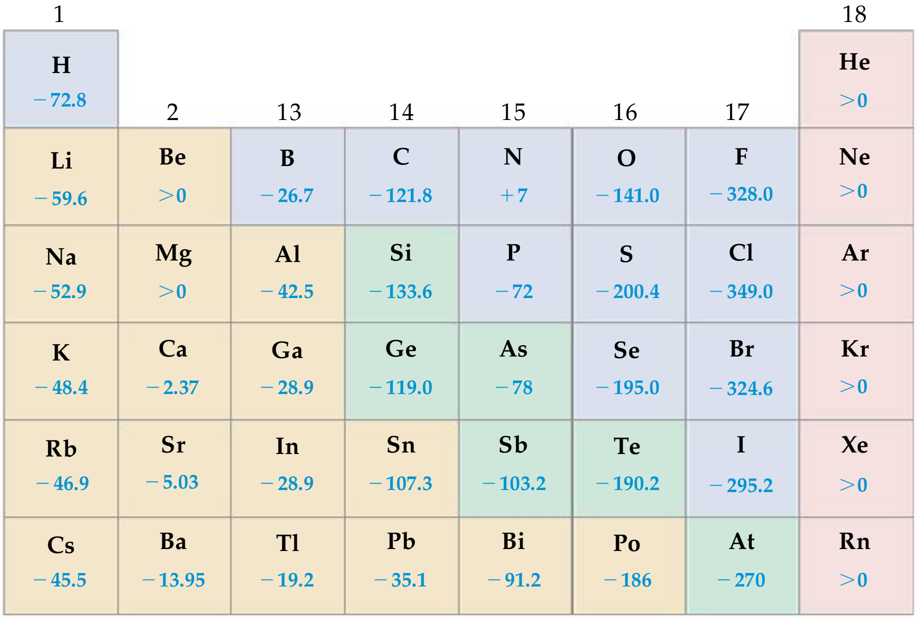
Ionization energy is the energy change for the removal of an electron. Let's consider the energy change associated with the addition of an electron. The thermochemical equation for the addition of an electron to a fluorine atom is

$$F(g) + e^- \rightarrow F^-(g) \qquad \Delta H_{ea} = -328\ \text{kJ mol}^{-1}$$

Notice that the process above is *exothermic*, meaning that energy is given off when an F atom gains an electron. **Electron affinity**, ***EA***, can be defined as the enthalpy change, ΔH_{ea}, that occurs when an atom in the gas phase gains an electron. According to this definition, the electron affinity of fluorine is a negative quantity.

We have defined electron affinity to reflect the tendency for a neutral atom to gain an electron. An alternative definition refers to the energy change in the process: $X^-(g) \longrightarrow X(g) + e^-$; that is, reflecting the tendency of an anion to lose an electron. This alternative definition leads to the opposite signs for *EA* values from those written in this text. You should be prepared to see electron affinities expressed in both ways in the chemical literature.

Some representative electron affinities are listed in Figure 9-11. It is more difficult to make generalizations about electron affinities than about ionization energies. The smaller atoms to the right of the periodic table (for example, group 17) tend to have large, negative electron affinities.* Electron affinities



1	2	13	14	15	16	17	18
H −72.8							He >0
Li −59.6	Be >0	B −26.7	C −121.8	N +7	O −141.0	F −328.0	Ne >0
Na −52.9	Mg >0	Al −42.5	Si −133.6	P −72	S −200.4	Cl −349.0	Ar >0
K −48.4	Ca −2.37	Ga −28.9	Ge −119.0	As −78	Se −195.0	Br −324.6	Kr >0
Rb −46.9	Sr −5.03	In −28.9	Sn −107.3	Sb −103.2	Te −190.2	I −295.2	Xe >0
Cs −45.5	Ba −13.95	Tl −19.2	Pb −35.1	Bi −91.2	Po −186	At −270	Rn >0

▶ FIGURE 9-11
Electron affinities of main-group elements
Values are in kilojoules per mole for the process $X(g) + e^- \longrightarrow X^-(g)$.

---

*It is somewhat awkward to speak of larger and smaller with the term *electron affinity*. A strong tendency to gain an electron, which implies a high "affinity" for an electron, as with F and Cl, is reflected through a *low* value of *EA*—a large *negative* value.

tend to become less negative in progressing toward the bottom of a group, with the notable exception of the second-period members of groups 15, 16, and 17 (namely, N, O, and F). It is likely that for these small atoms, an incoming electron encounters strong repulsive forces from other electrons in the atom and is thereby not as tightly bound as we might otherwise expect.

Some atoms have no tendency to gain an electron. This is the case with the noble gases, where an added electron would have to enter the empty *s* orbital of the next electronic shell. Other cases include the groups 2 and 12 elements, where the electron would have to enter the *p* subshell of the valence shell and a few other elements, such as Mn, where the electron would have to enter either the *p* subshell of the valence shell or a half-filled 3*d* subshell.

In considering the gain of a second electron by a nonmetal atom, we encounter positive electron affinities. Here the electron to be added is approaching not a neutral atom, but a negative ion. There is a strong repulsive force between the electron and the ion, and the energy of the system increases. Thus, for an element like oxygen, the first electron affinity is negative and the second is positive.

$$\begin{aligned} O(g) + e^- &\longrightarrow O^-(g) \qquad EA_1 = -141.0\ \text{kJ/mol} \\ O^-(g) + e^- &\longrightarrow O^{2-}(g) \qquad EA_2 = +744\ \text{kJ/mol} \end{aligned}$$

The high positive value of EA_2 makes the formation of *gaseous* O^{2-} seem very unlikely. The ion O^{2-} can exist, however, in ionic compounds, such as MgO(s), where formation of the ion is accompanied by other energetically favorable processes.

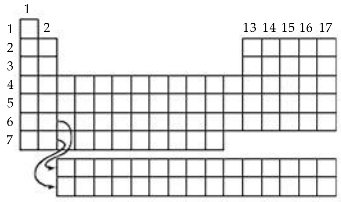
9-5 CONCEPT ASSESSMENT

On the blank periodic table in the margin locate the group expected to have:

(a) the most negative electron affinities in each period

(b) the least negative electron affinities in each period

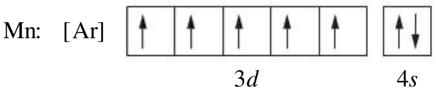
(c) all positive electron affinities in each period



9-6 Magnetic Properties

An important property related to the electron configurations of atoms and ions is their behavior in a magnetic field. A spinning electron is an electric charge in motion. It induces a magnetic field (recall the discussion on page 334). In a **diamagnetic** atom or ion, all electrons are paired and the individual magnetic effects cancel out. A diamagnetic species is weakly repelled by a magnetic field. A **paramagnetic** atom or ion has unpaired electrons, and the individual magnetic effects do not cancel out. The unpaired electrons possess a magnetic moment that causes the atom or ion to be attracted to an external magnetic field. The more unpaired electrons present, the stronger is this attraction.

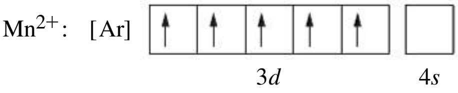
Manganese has a paramagnetism corresponding to five unpaired electrons, which is consistent with the electron configuration



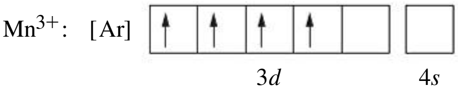
KEEP IN MIND

that it was the effect of the magnetic moments associated with the two different possibilities for an electron spin quantum number (equal in magnitude and opposite in sign) that allowed Stern and Gerlach to detect the presence of electron spin by using a magnetic field.

When a manganese atom loses two electrons, it becomes the ion Mn^{2+}, which is paramagnetic, and the strength of its paramagnetism corresponds to five unpaired electrons.



When a third electron is lost to produce Mn^{3+}, the ion has a paramagnetism corresponding to four unpaired electrons. The third electron lost is one of the unpaired 3*d* electrons.



EXAMPLE 9-4 Determining the Magnetic Properties of an Atom or Ion

Which of the following would you expect to be diamagnetic and which paramagnetic?

(a) Na atom **(b)** Mg atom **(c)** Cl^- ion **(d)** Ag atom

Analyze

To determine whether or not an atom or ion is paramagnetic, we need to determine the electronic configuration of the species.

Solve

(a) Paramagnetic. The Na atom has a single 3*s* electron outside the Ne core. This electron is unpaired.

(b) Diamagnetic. The Mg atom has *two* 3*s* electrons outside the Ne core. They must be paired, as are all the other electrons in the Ne core.

(c) Diamagnetic. Cl^- is isoelectronic with Ar, and Ar has all electrons paired $(1s^22s^22p^63s^23p^6)$.

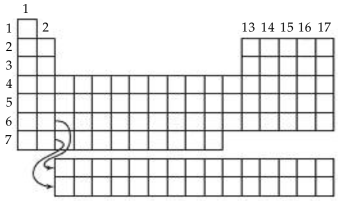
(d) Paramagnetic. We do not need to work out the exact electron configuration of Ag. Because the atom has 47 electrons—an odd number—at least one of the electrons must be unpaired (recall the Stern–Gerlach experiment, page 334).

Assess

We see that a quick method of determining the magnetic properties of an atom or an ion is to use that atomic number and add or subtract for anions and cations. If the resultant number is odd, then the species is paramagnetic. However, if the number is even, the species may or may not be diamagnetic, depending on the electronic configuration—for example, consider Ti.

PRACTICE EXAMPLE A: Which of the following are paramagnetic and which are diamagnetic: Zn, Cl, K^+, O^{2-}, and Al?

PRACTICE EXAMPLE B: Which has the greater number of unpaired electrons, Cr^{2+} or Cr^{3+}? Explain.



9-6 CONCEPT ASSESSMENT

On the blank periodic table in the margin locate the following:

(a) The period 4 transition element having a cation in the +3 oxidation state that is diamagnetic

(b) The period 5 element existing in the −2 oxidation state as an anion that is diamagnetic

(c) The period 4 transition element having a 2+ cation that is paramagnetic and has a half-filled *d* subshell

9-7 Periodic Properties of the Elements

As we noted at the beginning of the chapter, we can use the periodic law and the periodic table to predict some of the atomic, physical, and chemical properties of elements and compounds.

Atomic Properties

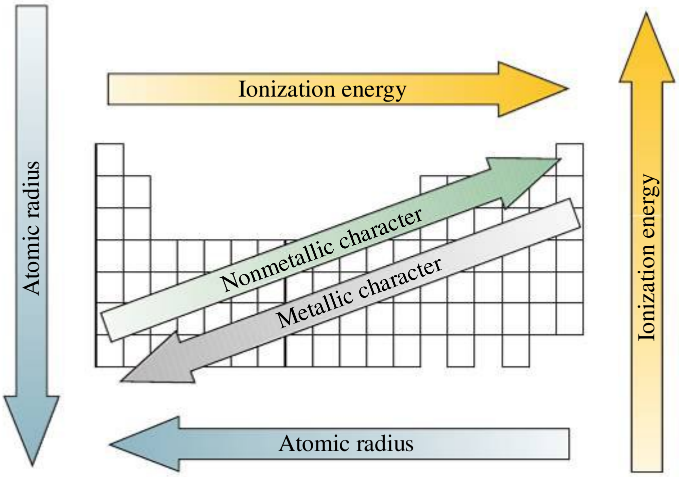
In this chapter we have learned how some atomic properties—atomic radius and ionization energy—vary within groups and periods of elements. We summarize these trends in relation to the periodic table in Figure 9-12. Trends are generally easy to apply within a group: The atomic radius of Sr is greater than that of Mg; both elements are in group 2. Usually, there is no difficulty in applying trends within a period either: The first ionization energy of P is greater than that of Mg; both elements are in the third period. However, comparing elements that are not within the same group or period can be difficult. The atomic radius of Sr is greater than that of P. Sr is farther down in its group of the periodic table and much farther to the left in its period than is P. Each of these directions is that of increasing atomic radius. We cannot, however, easily predict whether Mg or I has the larger atomic radius. The position of Mg to the left in its period suggests that Mg should have the larger radius, but the position of I toward the bottom of its group argues for I. Despite this limitation, you should find Figure 9-12 helpful in most cases.

Variation of Physical Properties Within a Group Table 9.5 lists some properties of three of the halogens (group 17). The table has two blank spaces for bromine. We fill in these blanks in Example 9-5 by making an assumption that works often enough to make it useful:

> The value of a property often changes uniformly from the top to the bottom of a group of elements in the periodic table.

TABLE 9.5 Some Properties of Three Halogen (Group 17) Elements

	Atomic Number	Atomic Mass, u	Molecular Form	Melting Point, K	Boiling Point, K
Cl	17	35.45	Cl_2	172	239
Br	35	79.90	Br_2	?	?
I	53	126.90	I_2	387	458



◀ FIGURE 9-12
Atomic properties and the periodic table—a summary
Atomic radius refers to metallic radius for metals and covalent radius for nonmetals. Ionization energies refer to first ionization energy. Metallic character relates generally to the ability to lose electrons, and nonmetallic character to the ability to gain electrons.

EXAMPLE 9-5 Using the Periodic Table to Estimate Physical Properties

Use data from Table 9.5 to estimate the boiling point of bromine.

Analyze

Remember that boiling points increase going down a group. As an initial guess we can consider the average between two elements.

Solve

The atomic number of bromine (35) is between the atomic numbers of chlorine (17) and iodine (53). Its atomic mass (79.90 u) is also intermediate to those of chlorine and iodine. (The average of the atomic masses of Cl and I is 81.18 u.) It is reasonable to expect that the boiling point of liquid bromine might also be intermediate to the boiling points of chlorine and iodine.

$$\text{bp } Br_2 \approx \frac{239\text{ K} + 458\text{ K}}{2} = 349\text{ K}$$

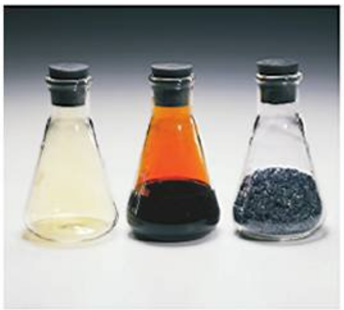
Assess

The observed boiling point is 332 K, which is close to the calculated result. A better estimate of the boiling point could possibly be made by plotting the known boiling points as a function of atomic mass, and then fitting the data.

PRACTICE EXAMPLE A: Estimate the melting point of bromine.

PRACTICE EXAMPLE B: Estimate the boiling point of astatine, At.

First, let us make some predictions about fluorine, the halogen not listed in Table 9.5. Its closest neighbor in group 17 is chlorine, which has a boiling point of 239 K (−34 °C); chlorine is a *gas* at room temperature (about 298 K). The other halogens are *liquid* bromine and *solid* iodine (Fig. 9-13). We would expect fluorine to have a lower melting point (mp) and lower boiling point (bp) than chlorine and also to be a gas at room temperature. (Observed values for F_2: mp = 53 K; bp = 85 K.)



▲ FIGURE 9-13
Three halogen elements
Chlorine is a yellow-green gas. Bromine is a dark red liquid. Iodine is a grayish black solid.

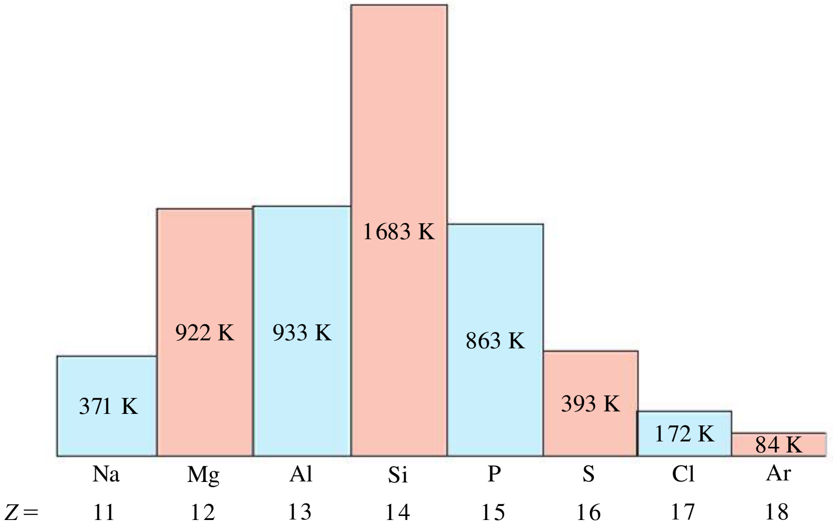
The generalization that a property varies uniformly within a group of the periodic table can work for compounds as well as for elements. Table 9.6 lists the melting points of two sets of compounds, binary carbon–halogen compounds and the *hydrogen halides*, HX (where X = F, Cl, Br, or I). We see that the melting points increase fairly uniformly with increasing molecular mass for the carbon–halogen compounds. This trend between melting point (and boiling point) and molecular mass can be explained in terms of intermolecular forces, as we will see in Chapter 12. Based on the melting points of HCl, HBr, and HI, the melting point of HF should be about −145 °C, but the observed value is −83.6 °C. Some factor other than molecular mass must be involved here. In Chapter 12, we will find that in HF there is a special intermolecular force of attraction that is missing or unimportant in the other compounds in Table 9.6.

TABLE 9.6 Melting Points of Two Series of Compounds

	Molecular Mass, u	Melting Point, °C
CF_4	88.0	−183.7
CCl_4	153.8	−22.9
CBr_4	331.6	90.1
CI_4	519.6	171
HF	20.0	−83.6
HCl	36.5	−114.2
HBr	80.9	−86.8
HI	127.9	−50.8

Variation of Physical Properties Across a Period A few properties vary regularly across a period. The ability to conduct heat and electricity are two that do. Thus, among the third-period elements, the metals Na, Mg, and Al have good thermal and electrical conductivities. The metalloid Si is only a fair conductor of heat and electricity, while the nonmetals P, S, Cl, and Ar are poor conductors.

In some cases, the trend in a property reverses direction in the period (similar to the trend in melting points of the hydrogen halides reversing direction



◀ FIGURE 9-14
Melting points of the third-period elements
Sometimes the trend in a property reverses direction within a period, as illustrated by this bar graph.

within a group). Consider, for example, the melting points of the third-period elements shown in a bar graph in Figure 9-14. Melting involves destruction of the orderly arrangement of the atoms or molecules in a crystalline solid. The amount of thermal energy needed for melting to occur, and hence the melting-point temperature, depends on the strength of the attractive forces between the atoms or molecules in the solid. For the metals Na, Mg, and Al, these forces are *metallic bonds*, which, roughly speaking, become stronger as the number of electrons available to participate in the bonding increases. Sodium, therefore, has the lowest melting point (371 K) of the third-period metals. With silicon, the forces between atoms are strong *covalent bonds* extending throughout the crystalline solid. Silicon has the highest melting point (1683 K) of the third-period elements. Phosphorus, sulfur, and chlorine exist as discrete molecules (P_4, S_8, and Cl_2). The bonds between atoms within molecules are strong, but *intermolecular forces*, the attractive forces between molecules, become progressively weaker across the period, and the melting points decrease. Argon atoms do not form molecules, and the forces between Ar atoms in solid argon are especially weak. Argon's melting point is the lowest for the entire period (84 K). The property of hardness also depends on forces between atoms and molecules in a solid. So the hardness of the solid third-period elements varies in much the same way as their melting points. Thus, on a 10-point scale in which solids are rated according to their abilities to scratch or abrade one another, sodium has a hardness of about 0.5; magnesium, 2; aluminum, 3; silicon, 7; and phosphorus and sulfur 1 to 2. Silicon has the greatest hardness.

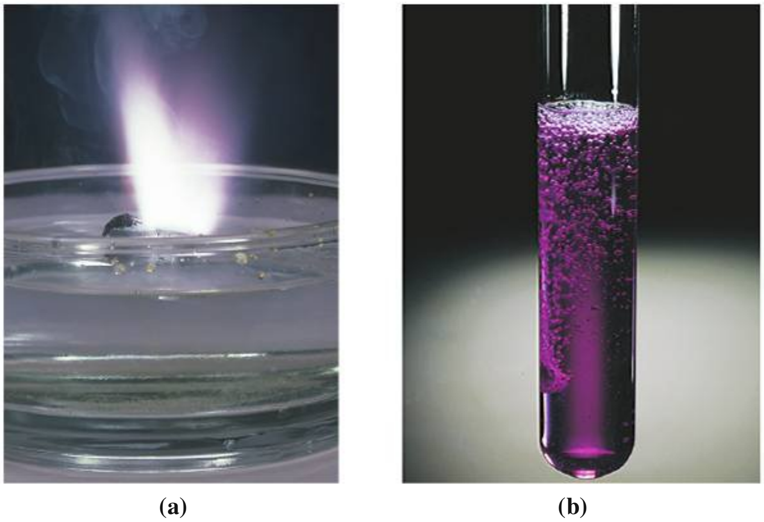
◀ When evaluating trends, it is often useful to sketch a graph showing the variation of the property.

◀ Metallic bonds are described in Section 11-7, covalent bonding in substances like silicon is discussed in Section 12-7, and the topic of intermolecular forces is examined throughout Chapter 12.

Reducing Abilities of Group 1 and 2 Metals We learned in Chapter 5 that a reducing agent makes possible a reduction half-reaction. The reducing agent itself, by losing electrons, is oxidized. In the following reactions, M, a group 1 or 2 metal, is the reducing agent and H_2O is the substance that is reduced.

$$2\,M(s) + 2\,H_2O(l) \longrightarrow 2\,M^+(aq) + 2\,OH^-(aq) + H_2(g) \qquad (M = \text{group 1 metal})$$
$$M(s) + 2\,H_2O(l) \longrightarrow M^{2+}(aq) + 2\,OH^-(aq) + H_2(g) \qquad (M = \text{Ca, Sr, Ba, or Ra})$$

At first guess, we might think that the lower the energy requirement for extracting electrons—the lower the ionization energy—the better the metal is as a reducing agent and the more vigorous its reaction with water. Potassium, for instance, has a lower ionization energy ($I_1 = 419$ kJ/mol) than does the next member of the fourth period, calcium ($I_1 = 590$; $I_2 = 1145$ kJ/mol). Our expectation is that potassium should react more vigorously with water than



(a) (b)

▶ FIGURE 9-15

A comparison of the reactions of potassium and calcium with water

(a) Potassium, a group 1 metal, reacts so rapidly that the hydrogen evolved bursts into flame. Notice that the metal is less dense than water. **(b)** Calcium, a group 2 metal, reacts more slowly than does potassium. Also, calcium is denser than water. The pink color of the acid–base indicator phenolphthalein signals the buildup of OH^- ions.

calcium does. This, indeed, is the case (Fig. 9-15). Mg and Be do not react with cold water as do the other alkaline earth metals. This might be explained in terms of the higher ionization energies for those two metals (Mg: $I_1 = 738$, $I_2 = 1451$ kJ/mol; Be: $I_1 = 900$, $I_2 = 1757$ kJ/mol).

Attributing the reactivity of these group 1 and 2 metals just to their ionization energies is an oversimplification, however. As long as the differences in ionization energies are very large, it is possible to make comparisons by considering only this factor. Where differences in ionization energies are smaller, though, other factors must also be considered, as we will see elsewhere in the text.

Oxidizing Abilities of the Halogen Elements (Group 17) An oxidizing agent gains the electrons that are lost in an oxidation half-reaction. The oxidizing agent, by gaining electrons, is itself reduced. Electron affinity is the atomic property introduced in this chapter that is related to the gain of electrons. We might expect an atom with a strong tendency to gain electrons (a large *negative* electron affinity) to take electrons away from atoms with low ionization energies—metals. In these terms, it is understandable that active metals form ionic compounds with active nonmetals. If M is a group 1 metal and X a group 17 nonmetal (halogen), this exchange of an electron leads to the formation of M^+ and X^- ions. In some cases, the reaction is especially vigorous (Fig. 9-16).

▲ FIGURE 9-16

Reaction of sodium metal and chlorine gas

The contents of the flask glow in this exothermic reaction between Na(s) and $Cl_2(g)$. The product is the ionic solid NaCl(s).

$$2\,M + X_2 \longrightarrow 2\,MX \qquad [\text{e.g.}, 2\,Na(s) + Cl_2(g) \longrightarrow 2\,NaCl(s)]$$

Another interesting oxidation–reduction reaction involving the halogens is a *displacement reaction*. Two halogens, one in molecular form and the other in ionic form, exchange places, as in this reaction (Fig. 9-17).

$$Cl_2(g) + 2\,I^-(aq) \longrightarrow I_2(aq) + 2\,Cl^-(aq)$$

We might think of this reaction as involving a competition between Cl and I atoms for an extra electron that only the I atoms (as I^-) have initially. The Cl atoms win out because they have a more negative electron affinity. (This is an oversimplified explanation, however, because strictly speaking electron affinities apply only to the behavior of isolated gaseous atoms and not to atoms in molecules or ions in solution.) By similar reasoning, can you see why no reaction occurs for this combination?

$$Br_2(l) + Cl^-(aq) \longrightarrow \text{no reaction}$$

Such predictions as those in the preceding paragraph work well for the halogens Cl_2, Br_2, and I_2, but not for F_2. We cannot account for the observed fact that F_2 is the strongest oxidizing agent among all chemical substances, just by considering electron affinities.

Acid–Base Nature of Element Oxides. Some metal oxides, such as Li_2O, react with water to produce the metal hydroxide.

$$\underset{\text{A basic oxide}}{Li_2O(s)} + H_2O(l) \longrightarrow \underbrace{2\,Li^+(aq) + 2\,OH^-(aq)}_{\text{Lithium hydroxide}}$$

These metal oxides are called *basic oxides* or *base anhydrides*. The term **anhydride** means “without water.” A “base without water” becomes a base when the water is added. Thus, the base anhydride Li_2O becomes the base LiOH, and BaO becomes $Ba(OH)_2$ after reaction with water. Moving from top to bottom down a group, the elements become more metallic, and their oxides become more basic.

Some nonmetal oxides react with water to produce an acidic solution. These are *acidic oxides* or *acid anhydrides*. $SO_2(g)$ reacts with water to produce H_2SO_3, a weak acid.

$$\underset{\text{An acidic oxide}}{SO_2(g)} + H_2O(l) \longrightarrow \underset{\text{Sulfurous acid}}{H_2SO_3(aq)}$$

Now let us examine the acid–base properties of the oxides of the third-period elements. We expect the metal oxides at the left of the period to be basic and the nonmetal oxides at the right to be acidic, but where and how does the changeover occur? Na_2O and MgO yield basic solutions in water. Cl_2O, SO_2, and P_4O_{10} produce acidic solutions. SiO_2 (quartz) does not dissolve in water. However, it does dissolve slightly in strongly basic solutions to produce silicates (similar to the carbonates formed by CO_2 in basic solutions). For this reason, we consider SiO_2 to be an acidic oxide.

Aluminum, a good conductor of heat and electricity, is clearly metallic in its physical properties. Al_2O_3, however, can act as either an acidic or a basic oxide. Oxides with this ability are called **amphoteric** (from the Greek word *amphos*, meaning “both”). Al_2O_3 is insoluble in water but exhibits its amphoterism by reacting with both acidic and basic solutions.

$$\underset{\text{Base}}{Al_2O_3(s)} + \underset{\text{Acid}}{6\,HCl(aq)} \longrightarrow 2\,AlCl_3(aq) + 3\,H_2O(l)$$

$$\underset{\text{Acid}}{Al_2O_3(s)} + \underset{\text{Base}}{2\,NaOH(aq)} + 3\,H_2O(l) \longrightarrow \underset{\text{Sodium aluminate}}{2\,Na[Al(OH)_4](aq)}$$

The amphoterism of Al_2O_3 signifies the point at which a changeover from basic to acidic oxides occurs in the third period of elements. Figure 9-18 summarizes the acid–base properties of the oxides of the main-group elements.

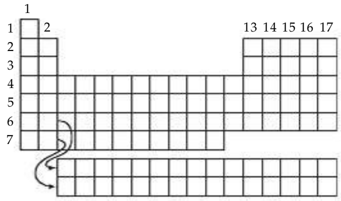
9-7 CONCEPT ASSESSMENT

On the blank periodic table in the margin locate the following:

(a) The group 13 element that is expected to form the most basic oxide
(b) The group 15 element that is expected to form the most acidic oxide
(c) The period 5 element that is expected to form the most basic oxide
(d) The period 5 element that is expected to form the most acidic oxide
(e) The period 3 element that exhibits amphoteric behavior



MasteringCHEMISTRY **www.masteringchemistry.com**

Based on its position in the periodic table, mercury should be a solid with a melting point well over 300 °C. Yet, it is a liquid at room temperature. For a discussion of why mercury is a liquid, unlike other metallic elements, go to the Focus On feature for Chapter 9, The Periodic Law and Mercury, on the MasteringChemistry site.

Summary

9-1 Classifying the Elements: The Periodic Law and the Periodic Table—The experimental basis of the periodic table of the elements is the **periodic law**: Certain properties recur periodically when the elements are arranged by increasing atomic number. The theoretical basis is that the properties of an element are related to the electron configuration of its atoms, and elements in the same group of the periodic table have similar electron configurations.

9-2 Metals and Nonmetals and Their Ions—The three classes of elements of the periodic table are the *nonmetals*, *metals*, and *metalloids*. **Metalloids** have some properties characteristic of metals and some characteristics of nonmetals. The nonmetals are further divided into the noble gases and the remainder of the main-group nonmetals, while the metals include the main-group metals and transition elements.

9-3 Sizes of Atoms and Ions—Types of atomic radii include **covalent radii**, **metallic radii**, and **van der Waals radii** (Fig. 9-3). In general, atomic radii decrease across a period and increase down a group of the periodic table (Figs. 9-4 and 9-9), mirroring the variation in **effective nuclear charge**, Z_{eff}, (equation 9.3) across a period and down a group. The **ionic radii** of positive ions are smaller than the neutral atom, whereas negative ions are larger than the parent atom (Figs. 9-7 and 9-8). Ionic radii exhibit adherence to the periodic law similar to that of atomic radii. When atoms or ions have the same number of electrons, they are said to be **isoelectronic**. When the radii of isoelectronic species are compared, the more negative the charge, the larger the radius of the ion or atom.

9-4 Ionization Energy—A study of **ionization energies**, I, shows that the periodic relationship observed is governed by the variation of Z_{eff}—that is, the ionization energy decreases down a group and increases across a period (Fig. 9-10, Tables 9.3 and 9.4).

9-5 Electron Affinity—**Electron affinity**, EA, is the energy change when an electron is added to a gaseous atom. Electron affinity does not exhibit clear-cut trends (Fig. 9-11).

9-6 Magnetic Properties—The magnetic properties of an atom or ion stem from the presence or absence of unpaired electrons. **Paramagnetic** atoms and ions have one or more unpaired electrons. In **diamagnetic** atoms and ions, all electrons are paired.

9-7 Periodic Properties of the Elements—The metallic, nonmetallic, and metalloid characteristics of atoms can be related to a set of atomic properties. In general, large atomic radii and low ionization energies are associated with metals; small atomic radii, high ionization energies, and large negative electron affinities are associated with nonmetals. Metalloids occur first in the third row (at Si) where the break between acid–base properties becomes less defined. Metals usually form oxides that give basic solutions, whereas nonmetal oxides form acidic solutions. The nonmetal oxide is called an **anhydride** since the addition of water gives an acid. At the break between clearly basic and acidic properties, some metals and metalloids exhibit **amphoteric** behavior because they react with both acids and bases (Fig. 9-18).

Integrative Example

When the ionization energies of a series of isoelectronic atoms and ions are compared, an interesting relationship is observed for some of them. In particular, if the square root of the ionization energy (in kJ mol^{-1}) for the series Li, Be^+, B^{2+}, C^{3+}, N^{4+}, O^{5+}, and F^{6+} is plotted against the atomic number (Z) of the species, a linear relationship is obtained. The corresponding graph for the series Na, Mg^+, Al^{2+}, Si^{3+}, P^{4+}, S^{5+}, and Cl^{6+}, is also linear. The graph is shown on page 387.

The equations for the two lines joining the points are

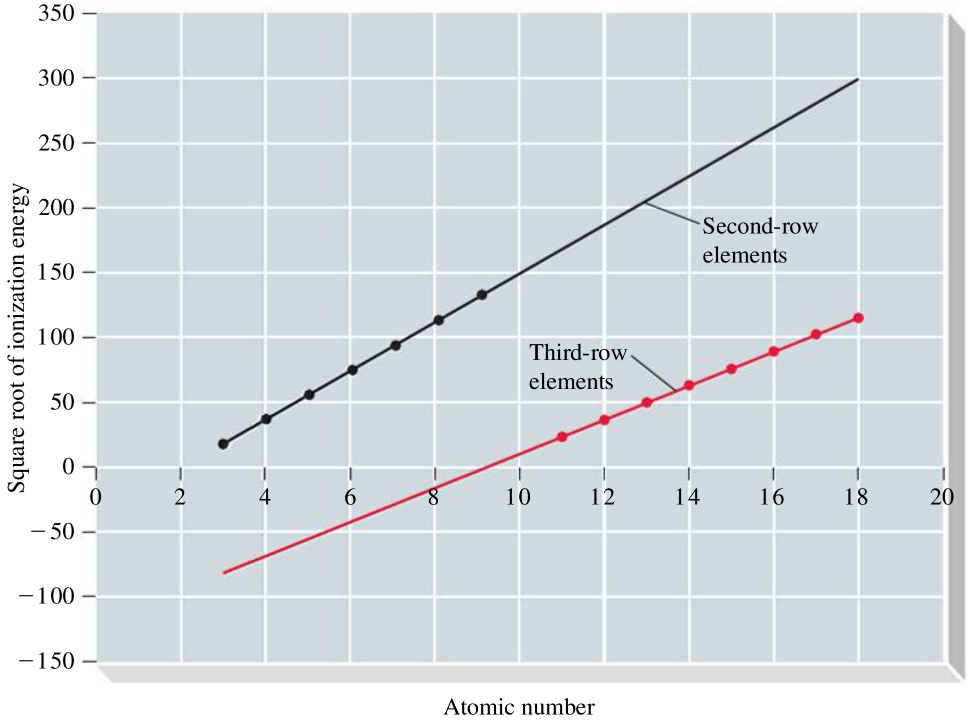
$$\textit{Second-row elements:} \qquad \sqrt{I} = 18.4Z - 32.0 \tag{9.7}$$

$$\textit{Third-row elements:} \qquad \sqrt{I} = 13.5Z - 124 \tag{9.8}$$

Explain the origin of these relationships and the differences in the numerical coefficients.

Analyze

We first notice that the electron configuration of the second-row atoms and ions is $1s^2 2s^1$, that is, a single electron $(2s^1)$ beyond the helium core $(1s^2)$. Similarly, for the third-row atoms and ions the electron configuration is $1s^2 2s^2 2p^6 3s^1$, that is, a single electron $(3s^1)$ beyond the neon core $(1s^2 2s^2 2p^6)$.



◀ Variation of $\sqrt{I}$ with atomic number for the second-row elements (black line) and the third-row elements (red line).

In both series of atoms and ions, the inner-core electrons screen the single valence-shell electron from the nucleus. These species are all reminiscent of the Bohr atom so that as an approximation we can use the expression for the energy levels for hydrogen-like atoms or hydrogen-like ions (equation 8.9). Specifically, we should be able to use equation (8.9) to derive equations for the energy required to remove the electron from the valence shells of a hydrogen-like species, that is, the ionization energy (I). Once we have these equations, we can compare them with the equations for the two straight-line graphs.

Solve

Equation (8.9), with the substitution $Z = Z_{\text{eff}}$, produces equation (9.4); and with the further substitution $R_H = 2.178 \times 10^{-18}$ J, we have

$$E_n = -2.178 \times 10^{-18}\left(\frac{Z_{\text{eff}}^2}{n^2}\right)\text{J}$$

E_n in equations (8.9) and (9.4) has the unit J atom^{-1}, which must be converted to kJ mol^{-1}—the unit of I in the two straight-line equations given to us.

$$E_n = -2.178 \times 10^{-18}\frac{\text{J}}{\text{atom}} \times 6.022 \times 10^{23}\frac{\text{atom}}{\text{mol}} \times \frac{Z_{\text{eff}}^2}{n^2}$$
$$= -1.3116 \times 10^{6}\frac{Z_{\text{eff}}^2}{n^2}\text{J mol}^{-1} \times \frac{1\text{ kJ}}{1000\text{ J}}$$

The energy required to remove an electron from an orbital with principal quantum number n in a hydrogen-like species—the ionization energy—is the *negative* of that shown above, that is,

$$I = -E_n = 1311.6 \times \frac{Z_{\text{eff}}^2}{n^2}\text{kJ mol}^{-1} \qquad \textbf{(9.9)}$$

Equation (9.9) shows that the ionization energy (I) is a linear function of $(Z_{\text{eff}})^2$ and the straight-line graphs (equations 9.7 and 9.8) show that $\sqrt{I}$ is a linear function of Z. We are on the right track. However, we must now take into account that we are considering one-electron systems with a nucleus shielded by a closed shell.

First consider the second-row series $(\text{Li}, \text{Be}^+, \text{B}^{2+}, \text{C}^{3+}, \text{N}^{4+}, \text{O}^{5+}, \text{and F}^{6+})$, all members of which have the electron configuration $1s^2 2s^1$. If we assume that the closed shell $1s^2$ perfectly screens the outer electron $2s^1$, the value of Z_{eff} for this series will be $Z - 2$. Thus we should substitute $Z_{\text{eff}} = Z - 2$ into equation (9.9), and also $n = 2$ since ionization occurs from the 2*s* orbital, to obtain

$$I = 1311.6 \times \frac{(Z-2)^2}{n^2} = 1311.6 \times \frac{(Z-2)^2}{2^2}$$

Taking the square root of both sides and clearing the fraction gives

$$\sqrt{I} = 36.22 \times \left(\frac{Z-2}{2}\right) = 18.11Z - 36.22 \qquad \textbf{(9.10)}$$

Let us now look at the third-row series. In this case the configuration of the isoelectronic series is $1s^22s^22p^63s^1$ so that if we assume perfect screening of the $3s^1$ electron by the ten inner-core electrons we have

$$Z_{\text{eff}} = Z - 10$$

Proceeding as before and remembering that ionization occurs from the $n = 3$ level, we obtain

$$I = 1311.6 \times \frac{(Z-10)^2}{n^2} = 1311.6 \times \frac{(Z-10)^2}{3^2}$$

and

$$\sqrt{I} = 36.22 \times \left(\frac{Z-10}{3}\right) = 12.07Z - 120.7 \qquad \textbf{(9.11)}$$

Assess

In comparing equations (9.10) and (9.11), we find that the difference in the slope (coefficient for Z) is due to the difference in the principal quantum number of the orbital from which the ionization occurs. The difference in the intercepts is due both to the principal quantum number from which the ionization occurs and to the number of electrons screening the valence-shell electron.

Equation (9.10) for the second-row elements is in remarkable agreement with the empirically observed equation (9.7) at the beginning of this example, especially considering our use of the modified Bohr model.

Although the general form of equation (9.11) is correct for the third-row series, the agreement between the numerical constants is not as good. This is to be expected because we have assumed perfect screening by the core electrons, which completely ignores the different characteristics of the electrons composing the inner core. The intricate, correlated motions of the electrons in the core leads to a complicated combination of screening and penetration that cannot be accounted for with our simple model.

PRACTICE EXAMPLE A: Francium ($Z = 87$) is an extremely rare radioactive element formed when actinium ($Z = 89$) undergoes alphaparticle emission. Francium occurs in natural uranium minerals, but estimates are that little more than 15 g of francium exists in the top 1 km of Earth's crust. Few of francium's properties have been measured, but some can be inferred from its position in the periodic table. Estimate the melting point, density, and atomic (metallic) radius of francium.

PRACTICE EXAMPLE B: Discuss the likelihood that element 168, should it ever be synthesized in sufficient quantity, would be a "noble liquid" at 298 K and 1 bar. Some data that might be useful appear in the table below. Could element 168 be a "noble solid" at 298 K and 1 bar? Use *spdf* notation to show the electron configuration you would expect for element 168.

Element	Atomic Mass, u	mp, K	bp, K
Argon	39.948	83.95	87.45
Helium	4.0026		4.25
Krypton	83.80	116.5	120.9
Neon	20.179	24.48	27.3
Radon	222	202	211.4
Xenon	131.29	161.3	166.1

Exercises

The Periodic Law

1. Use data from Figure 9-1 and equation (9.1) to estimate the density of the recently discovered element 114. Assume a mass number of 298.

2. Suppose that lanthanum $(Z = 57)$ were a newly discovered element having a density of $6.145\,\text{g/cm}^3$. Estimate its molar mass.

3. The following densities, in grams per cubic centimeter, are for the listed elements in their standard states at 298 K. Show that density is a periodic property of these elements: Al, 2.699; Ar, 0.0018; As, 5.778; Br, 3.100; Ca, 1.550; Cl, 0.0032; Ga, 5.904; Ge, 5.323; Kr, 0.0037; Mg, 1.738; P, 1.823; K, 0.856; Se, 4.285; Si, 2.336; Na, 0.968; S, 2.069.

4. The following melting points are in degrees Celsius. Show that melting point is a periodic property of these elements: Al, 660; Ar, −189; Be, 1278; B, 2300; C, 3350; Cl, −101; F, −220; Li, 179; Mg, 651; Ne, −249; N, −210; O, −218; P, 590; Si, 1410; Na, 98; S, 119.

The Periodic Table

5. Mendeleev's periodic table did not preclude the possibility of a new group of elements that would fit within the existing table, as was the case with the noble gases. Moseley's work did preclude this possibility. Explain this difference.

6. Explain why the several periods in the periodic table do not all have the same number of members.

7. Assuming that the seventh period is 32 members long, what should be the atomic number of the noble gas following radon (Rn)? Of the alkali metal following francium (Fr)? What would you expect their approximate atomic masses to be?

8. Concerning the incomplete seventh period of the periodic table, what should be the atomic number of the element **(a)** for which the filling of the 6*d* subshell is completed; **(b)** that should most closely resemble bismuth; **(c)** that should be a noble gas?

Atomic Radii and Ionic Radii

9. For each of the following pairs, indicate the atom that has the *larger* size: **(a)** Te or Br; **(b)** K or Ca; **(c)** Ca or Cs; **(d)** N or O; **(e)** O or P; **(f)** Al or Au.

10. Indicate the *smallest* and the *largest* species (atom or ion) in the following group: Al atom, F atom, As atom, Cs^+ ion, I^- ion, N atom.

11. Explain why the radii of atoms do not simply increase uniformly with increasing atomic number.

12. The masses of individual atoms can be determined with great precision, yet there is considerable uncertainty about the exact size of an atom. Explain why this is the case.

13. Which is **(a)** the smallest atom in group 13; **(b)** the smallest of the following atoms: Te, In, Sr, Po, Sb? Why?

14. How would you expect the sizes of the hydrogen ion, H^+, and the hydride ion, H^-, to compare with that of the H atom and the He atom? Explain.

15. Arrange the following in expected order of increasing radius: Br, Li^+, Se, I^-. Explain your answer.

16. Explain why the generalizations presented in Figure 9-12 cannot be used to answer the question, Which is larger, an Al atom or an I atom?

17. Among the following ions, several pairs are *isoelectronic*. Identify these pairs. Fe^{2+}, Sc^{3+}, Ca^{2+}, F^-, Co^{2+}, Co^{3+}, Sr^{2+}, Cu^+, Zn^{2+}, Al^{3+}.

18. The following species are isoelectronic with the noble gas krypton. Arrange them in order of increasing radius and comment on the principles involved in doing so: Rb^+, Y^{3+}, Br^-, Sr^{2+}, Se^{2-}.

19. All the isoelectronic species illustrated in the text had the electron configurations of noble gases. Can two ions be isoelectronic *without* having noble-gas electron configurations? Explain.

20. Is it possible for two different atoms to be isoelectronic? two different cations? two different anions? a cation and an anion? Explain.

Ionization Energies; Electron Affinities

21. Use principles established in this chapter to arrange the following atoms in order of *increasing* value of the first ionization energy: Sr, Cs, S, F, As.

22. Are there any atoms for which the second ionization energy (I_2) is smaller than the first (I_1)? Explain.

23. Some electron affinities are negative quantities, and some are zero or positive. Why is this not also the case with ionization energies?

24. How much energy, in joules, must be absorbed to convert to Na^+ all the atoms present in 1.00 mg of *gaseous* Na? The first ionization energy of Na is 495.8 kJ/mol.

25. How much energy, in kilojoules, is required to remove all the third-shell electrons in a mole of gaseous silicon atoms?

26. What is the maximum number of Cs^+ ions that can be produced per joule of energy absorbed by a sample of gaseous Cs atoms?

27. The production of gaseous bromide ions from bromine molecules can be considered a two-step process in which the first step is

$$Br_2(g) \longrightarrow 2\,Br(g) \qquad \Delta H = +193\text{ kJ}$$

Is the formation of $Br^-(g)$ from $Br_2(g)$ an endothermic or exothermic process?

28. Use ionization energies and electron affinities listed in the text to determine whether the following reaction is endothermic or exothermic.

$$Mg(g) + 2\,F(g) \longrightarrow Mg^{2+}(g) + 2\,F^-(g)$$

29. The Na^+ ion and the Ne atom are isoelectronic. The ease of loss of an electron by a gaseous Ne atom, I_1, has a value of 2081 kJ/mol. The ease of loss of an electron from a gaseous Na^+ ion, I_2, has a value of 4562 kJ/mol. Why are these values not the same?

30. From the data in Figure 9-11, the formation of a gaseous anion Li^- appears energetically favorable. That is, energy is given off when gaseous Li atoms accept electrons. Comment on the likelihood of forming a stable compound containing the Li^- ion, such as Li^+Li^- or Na^+Li^-.

31. Compare the elements Al, Si, S, and Cl.
(a) Place the elements in order of increasing ionization energy.
(b) Place the elements in order of increasing electron affinity.

32. Compare the elements Na, Mg, O, and P.
(a) Place the elements in order of increasing ionization energy.
(b) Place the elements in order of increasing electron affinity.

Magnetic Properties

33. Unpaired electrons are found in only one of the following species. Indicate which one, and explain why: $F^-, Ca^{2+}, Fe^{2+}, S^{2-}$.

34. Which of the following species has the greatest number of unpaired electrons **(a)** Ge; **(b)** Cl; **(c)** Cr^{3+}; **(d)** Br^-?

35. Which of the following species would you expect to be diamagnetic and which paramagnetic? **(a)** K^+; **(b)** Cr^{3+}; **(c)** Zn^{2+}; **(d)** Cd; **(e)** Co^{3+}; **(f)** Sn^{2+}; **(g)** Br.

36. Write electron configurations consistent with the following data on numbers of unpaired electrons: Ni^{2+}, 2; Cu^{2+}, 1; Cr^{3+}, 3.

37. Must all atoms with an odd atomic number be paramagnetic? Must all atoms with an even atomic number be diamagnetic? Explain.

38. Neither Co^{2+} nor Co^{3+} has 4*s* electrons in its electron configuration. How many unpaired electrons would you expect to find in each of these ions? Explain.

Predictions Based on the Periodic Table

39. Use ideas presented in this chapter to indicate **(a)** three metals that you would expect to exhibit the photoelectric effect with visible light and three that you would not; **(b)** the noble gas element that should have the highest density in the liquid state; **(c)** the approximate I_1 of fermium ($Z = 100$); **(d)** the approximate density of solid radium ($Z = 88$).

40. The heat of atomization for an element is the amount of energy required to convert an appropriate amount of an element in its standard state to a mole of atoms in the gaseous state. The heats of atomization, in kilojoules per mole, for three of the group 14 elements are carbon, 717; silicon, 452; and tin, 302 kJ/mol. Predict the heat of atomization of germanium.

41. Gallium is a commercially important element (used to make gallium arsenide for the semiconductor industry). Although gallium was unknown in Mendeleev's time, he predicted properties of this element. Predict the following for gallium: **(a)** density; **(b)** the formula and percent composition of its oxide. [*Hint:* Use Figure 9-1, equation (9.1), and Mendeleev's periodic table (page 362).]

42. For the following groups of elements, select the one that has the property noted:
(a) the largest atom: Mg, Mn, Mo, Ba, Bi, Br
(b) the lowest first ionization energy: B, Sr, Al, Br, Mg, Pb

(c) the most negative electron affinity: As, B, Cl, K, Mg, S

(d) the largest number of unpaired electrons: F, N, S^{2-}, Mg^{2+}, Sc^{3+}, Ti^{3+}

43. The boiling points of the noble gases increase down the group as follows: He, 4.2; Ne, 27.1; Ar, 87.3; Kr, 119.7; and Xe, 165 K. What would you predict to be the boiling point of radon?

44. Estimate the missing boiling point in the following series of compounds.

(a) CH_4, −164 °C; SiH_4, −112 °C; GeH_4, −90 °C; SnH_4, ? °C

(b) H_2O, ? °C; H_2S, −61 °C; H_2Se, −41 °C; H_2Te, −2 °C

Does your estimate in part (b) agree with the known value?

45. Match each of the lettered items on the left with an appropriate numbered item on the right. All the numbered items should be used, and some more than once.

(a) $Z = 32$
(b) $Z = 8$
(c) $Z = 53$
(d) $Z = 38$
(e) $Z = 48$
(f) $Z = 20$

1. two unpaired p electrons
2. diamagnetic
3. more negative electron affinity than elements on either side of it in the same period
4. first ionization energy lower than that of Ca but greater than that of Cs

46. Match each of the lettered items in the column on the left with the most appropriate numbered item(s) in the column on the right. Some of the numbered items may be used more than once and some not at all.

(a) Tl
(b) $Z = 70$
(c) Ni
(d) $[Ar]4s^2$
(e) a metalloid
(f) a nonmetal

1. an alkaline earth metal
2. element in period 5 and group 15
3. largest atomic radius of all the elements
4. an element in period 4 and group 16
5. $3d^8$
6. one p electron in the shell of highest n
7. lowest ionization energy of all the elements
8. an f-block element

47. Which of the following ions are unlikely to be found in chemical compounds: K^+, Ga^{4+}, Fe^{6+}, S^{2-}, Ge^{5+}, or Br^-? Explain briefly.

48. Which of the following ions are likely to be found in chemical compounds: Na^{2+}, Li^+, Al^{4+}, F^{2-}, or Te^{2-}? Explain briefly.

Integrative and Advanced Exercises

49. Complete and balance the following equations. If no reaction occurs, so state.

(a) $Rb(s) + H_2O(l) \longrightarrow$

(b) $I_2(s) + Na^+(aq) + Br^-(aq) \longrightarrow$

(c) $SrO(s) + H_2O(l) \longrightarrow$

(d) $SO_3(g) + H_2O(l) \longrightarrow$

50. Write balanced equations to represent

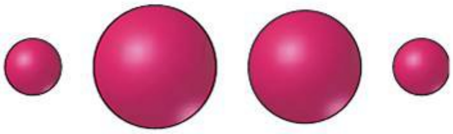
(a) the displacement of a halide anion from aqueous solution by liquid bromine

(b) the reaction with water of an alkali metal with $Z > 50$

(c) the reaction of tetraphosphorus decoxide with water

(d) the reaction of aluminum oxide with aqueous sulfuric acid

51. Four atoms and/or ions are sketched below in accordance with their relative atomic and/or ionic radii.



Which of the following sets of species are compatible with the sketch? Explain. **(a)** C, Ca^{2+}, Cl^-, Br^-; **(b)** Sr, Cl, Br^-, Na^+; **(c)** Y, K, Ca, Na^+; **(d)** Al, Ra^{2+}, Zr^{2+}, Mg^{2+}; **(e)** Fe, Rb, Co, Cs.

52. Sketch a periodic table that would include *all* the elements in the main body of the table. How many "numbers" wide would the table be?

53. In Mendeleev's time, indium oxide, which is 82.5% In by mass, was thought to be InO. If this were the case, in which group of Mendeleev's table (page 362) should indium be placed?

54. Instead of accepting the atomic mass of indium implied by the data in Exercise 53, Mendeleev proposed that the formula of indium oxide is In_2O_3. Show that this assumption places indium in the proper group of Mendeleev's periodic table on page 362.

55. Listed below are two atomic properties of the element germanium. Refer only to the periodic table on the inside front cover and indicate probable values for each of the following elements, expressed as greater than, about equal to, or less than the value for Ge.

Element	Atomic Radius	First Ionization Energy
Ge	122 pm	762 kJ/mol
Al	?	?
In	?	?
Se	?	?

56. In estimating the boiling point and melting point of bromine in Example 9-5, could we have used Celsius or Fahrenheit instead of Kelvin temperature? Explain.

57. In the formula X_2, if the two X atoms are the same halogen, the substance is a halogen element (for example, Cl_2, Br_2). If the two X atoms are different halogens (such as Cl and Br), the substance is an *interhalogen compound*. Use data from Table 9.5 to estimate the melting points and boiling points of the interhalogen compounds BrCl and ICl.

58. Refer to Figure 9-9 and explain why the difference between the ionic radii of the 1− and 2− anions does not remain constant from top to bottom of the periodic table.

59. Explain why the third ionization energy of Li(g) is an easier quantity to calculate than either the first or second ionization energies. Calculate I_3 for Li, and express the result in kJ/mol.

60. Two elements, A and B, have the electron configurations shown.

$$\text{A} = [\text{Ar}]4s^1 \qquad \text{B} = [\text{Ar}]3d^{10}4s^24p^3$$

(a) Which element is a metal?
(b) Which element has the greater ionization energy?
(c) Which element has the larger atomic radius?
(d) Which element has the greater electron affinity?

61. Two elements, A and B, have the electron configurations shown.

$$\text{A} = [\text{Kr}]4s^2 \qquad \text{B} = [\text{Ar}]3d^{10}4s^24p^5$$

(a) Which element is a metal?
(b) Which element has the greater ionization energy?
(c) Which element has the larger atomic radius?
(d) Which element has the greater electron affinity?

62. Studies done in 1880 showed that a chloride of uranium had 37.34% Cl by mass and an approximate formula mass of 382 u. Other data indicated the specific heat of uranium to be 0.0276 cal $g^{-1}\,°C^{-1}$. Are these data in agreement with the atomic mass of uranium assigned by Mendeleev, 240 u? [*Hint:* Refer to Feature Problem 121 of Chapter 7.]

63. Assume that atoms are hard spheres, and use the metallic radius of 186 pm for Na to estimate the volumes of one Na atom and of one mole of Na atoms. How does your result compare with the atomic volume found in Figure 9-1? Why is there so much disagreement between the two values?

64. When sodium chloride is strongly heated in a flame, the flame takes on the yellow color associated with the emission spectrum of sodium atoms. The reaction that occurs in the *gaseous* state is

$$\text{Na}^+(g) + \text{Cl}^-(g) \longrightarrow \text{Na}(g) + \text{Cl}(g).$$

Calculate ΔH for this reaction.

65. Use information from Chapters 8 and 9 to calculate the *second* ionization energy for the He atom. Compare your result with the tabulated value of 5251 kJ/mol.

66. Refer only to the periodic table on the inside front cover, and arrange the following ionization energies in order of increasing value: I_1 for F; I_2 for Ba; I_3 for Sc; I_2 for Na; I_3 for Mg. Explain the basis of any uncertainties.

67. Refer to the footnote on page 375. Then use values of basic physical constants and other data from the appendices to show that 1 eV/atom = 96.49 kJ/mol.

68. Plot a graph of the square roots of the ionization energies versus the nuclear charge for the two series Li, Be^+, B^{2+}, C^{3+}, and Na, Mg^+, Al^{2+}, Si^{3+}. Explain the observed relationship with the aid of Bohr's expression for the binding energy of an electron in a one-electron atom.

Feature Problems

69. The work functions for a number of metals are given in the following table. How do the work functions vary
(a) down a group?
(b) across a period?
(c) Estimate the work function for potassium and compare it with a published value.
(d) What periodic property is the work function most like?

Metal	Work Function, J × 10^{19}
Al	6.86
Cs	3.45
Li	4.6
Mg	5.86
Na	4.40
Rb	3.46

70. The following are a few elements and their characteristic X-ray wavelengths:

Element	X-ray Wavelength, pm
Mg	987
S	536
Ca	333
Cr	229
Zn	143
Rb	93

Use these data to determine the constants *A* and *b* in Moseley's relationship (page 363). Compare your value of *A* with the value obtained from Bohr's theory for the frequencies emitted by one-electron atoms. Suggest a reasonable interpretation of the quantity *b*.

71. Gaseous sodium atoms absorb quanta with the energies shown in the table below.

Energy of Quanta, kJ mol^{-1}	Electron Configuration
0	$[\text{Ne}]3s^1$
203	$[\text{Ne}]3p^1$
308	$[\text{Ne}]4s^1$
349	$[\text{Ne}]3d^1$
362	$[\text{Ne}]4p^1$

(a) The ionization energy of the ground state is 496 kJ mol^{-1}. Calculate the ionization energies for each of the states given in the table.
(b) Calculate Z_{eff} for each state.
(c) Calculate $\bar{r}_{nl}$ for each state.
(d) Interpret the results obtained from parts (b) and (c) in terms of penetration and screening.

72. A method for estimating electron affinities is to extrapolate Z_{eff} values for atoms and ions that contain the same number of electrons as the negative ion of interest. Use the data in the table on the next page to answer the questions that follow.

Atom or Ion: $I(\text{kJ mol}^{-1})$	Atom or Ion: $I(\text{kJ mol}^{-1})$	Atom or Ion: $I(\text{kJ mol}^{-1})$
Ne: 2080	F: 1681	O: 1314
Na^+: 4565	Ne^+: 3963	F^+: 3375
Mg^{2+}: 7732	Na^{2+}: 6912	Ne^{2+}: 6276
Al^{3+}: 11,577	Mg^{3+}: 10,548	Na^{3+}: 9540

(a) Estimate the electron affinity of F, and compare it with the experimental value.
(b) Estimate the electron affinities of O and N.
(c) Examine your results in terms of penetration and screening.

73. We have seen that the wave functions of hydrogen-like atoms contain the nuclear charge Z for hydrogen-like atoms and ions, but modified through equation (9.3) to account for the phenomenon of shielding or screening. In 1930, John C. Slater devised the following set of empirical rules to calculate a shielding constant for a designated electron in the orbital ns or np:

(i) Write the electron configuration of the element, and group the subshells as follows: $(1s),(2s,2p),(3s,3p),(3d),(4s,4p),(4d),(4f),(5s,5p)$, etc.
(ii) Electrons in groups to the right of the (ns, np) group contribute nothing to the shielding constant for the designated electron.
(iii) All the other electrons in the (ns, np) group shield the designated electron to the extent of 0.35 each.
(iv) All electrons in the $n - 1$ shell shield to the extent of 0.85 each.
(v) All electrons in the $n - 2$ shell, or lower, shield completely—their contributions to the shielding constant are 1.00 each.

When the designated electron being shielded is in an nd or nf group, rules (ii) and (iii) remain the same but rules (iv) and (v) are replaced by

(vi) Each electron in a group lying to the left of the nd or nf group contributes 1.00 to the shielding constant.

These rules are a simplified generalization based on the average behavior of different types of electrons. Use these rules to do the following:
(a) Calculate Z_{eff} for a valence electron of oxygen.
(b) Calculate Z_{eff} for the 4s electron in Cu.
(c) Calculate Z_{eff} for a 3d electron in Cu.
(d) Evaluate the Z_{eff} for the valence electrons in the group 1 elements (including H), and show that the ionization energies observed for this group are accounted for by using the Slater rules. [*Hint:* Do not overlook the effect of n on the orbital energy.]
(e) Evaluate Z_{eff} for a valence electron in the elements Li through Ne, and use the results to explain the observed trend in first ionization energies for these elements.
(f) Using the radial functions given in Table 8.1 and Z_{eff} estimated with the Slater rules, compare plots of the radial probability for the 3s, 3p, and 3d orbitals for the H atom and the Na atom. What do you observe from these plots regarding the effect of shielding on radial probability distributions?

Self-Assessment Exercises

74. In your own words, define the following terms: **(a)** isoelectronic; **(b)** valence-shell electrons; **(c)** metal; **(d)** nonmetal; **(e)** metalloid.

75. Briefly describe each of the following ideas or phenomena: **(a)** the periodic law; **(b)** ionization energy; **(c)** electron affinity; **(d)** paramagnetism.

76. Explain the important distinctions between each pair of terms: **(a)** actinide and lanthanide element; **(b)** covalent and metallic radius; **(c)** atomic number and effective nuclear charge; **(d)** ionization energy and electron affinity; **(e)** paramagnetic and diamagnetic.

77. The element whose atoms have the electron configuration $[\text{Kr}]4d^{10}5s^25p^3$ **(a)** is in group 13 of the periodic table; **(b)** bears a similarity to the element Bi; **(c)** is similar to the element Te; **(d)** is a transition element.

78. The fourth-period element with the largest atom is **(a)** K; **(b)** Br; **(c)** Pb; **(d)** Kr.

79. The largest of the following is **(a)** an Ar atom; **(b)** a K^+ ion; **(c)** a Ca^{2+} ion; **(d)** a Cl^- ion.

80. The highest first ionization energy of the following is that of **(a)** Cs; **(b)** Cl; **(c)** I; **(d)** Li.

81. The most negative electron affinity of the following elements is that of **(a)** Br; **(b)** Sn; **(c)** Ba; **(d)** Li.

82. An ion that is isoelectronic with Se^{2-} is **(a)** S^{2-}; **(b)** I^-; **(c)** Xe; **(d)** Sr^{2+}.

83. Write electron configurations to show the first two ionizations for Cs. Explain why the second ionization energy is much greater than the first.

84. Explain why the first ionization energy of Mg is greater that of Na, whereas the second ionization of Na is greater than that of Mg.

85. Answer each of the following questions:
(a) Which of the elements P, As, and S has the largest atomic radius?
(b) Which of the following has the smallest radius: Xe, O^{2-}, N^{3-}, or F^-?
(c) Which should have the largest difference between the first and second ionization energy: Al, Si, P, or Cl?
(d) Which has the largest ionization energy: C, Si, or Sn?
(e) Which has the largest electron affinity: Na, B, Al, or C?

86. The first ionization energies of Si, P, S, and Cl are given in Table 9.4. Briefly provide an explanation for this trend.

87. Find three pairs of elements that are out of order in the periodic table in terms of their atomic masses. Why is it necessary to invert their order in the table?

88. For the atom $^{119}_{50}\text{Sn}$, indicate the number of **(a)** protons in the nucleus; **(b)** neutrons in the nucleus; **(c)** 4d electrons; **(d)** 3s electrons; **(e)** 5p electrons; **(f)** electrons in the valence shell.

89. Refer to the periodic table on the inside front cover and indicate **(a)** the most nonmetallic element; **(b)** the transition metal with lowest atomic number; **(c)** a metalloid whose atomic number is exactly midway between those of two noble gas elements.

90. Give the symbol of the element **(a)** in group 14 that has the smallest atoms; **(b)** in period 5 that has the largest atoms; **(c)** in group 17 that has the lowest first ionization energy.

91. Refer only to the periodic table on the inside front cover and indicate which of the atoms, Bi, S, Ba, As, and Ca, **(a)** is most metallic; **(b)** is most nonmetallic; **(c)** has the intermediate value when the five are arranged in order of increasing first ionization energy.

92. Arrange the following elements in order of decreasing metallic character: Sc, Fe, Rb, Br, O, Ca, F, Te.

93. In multielectron atoms many of the periodic trends can be explained in terms of Z_{eff}. Consider the following statements and discuss whether or not the statement is true or false.

(a) Electrons in a *p* orbital are more effective than electrons in the *s* orbitals in shielding other electrons from the nuclear charge.

(b) Z_{eff} for an electron in an *s* orbital is lower than that for an electron in a *p* orbital in the same shell.

(c) Z_{eff} is usually less than Z.

(d) Electrons in orbitals having $\ell = 1$ penetrate better than those with $\ell = 2$.

(e) Z_{eff} for the orbitals of the elements Na(3*s*), Mg(3*s*), Al(3*p*), P(3*p*), and S(3*p*) are in the order $Z_{\text{eff}}(\text{Na}) < Z_{\text{eff}}(\text{Mg}) > Z_{\text{eff}}(\text{Al}) < Z_{\text{eff}}(\text{P}) > Z_{\text{eff}}(\text{S})$.

94. Consider a nitrogen atom in the ground state and comment on whether the following statements are true or false.

(a) Z_{eff} for an electron in a 2*s* orbital is greater than that for the 1*s* orbital.

(b) The Z_{eff} for the 2*p* and 2*s* orbitals is the same.

(c) More energy is required to remove an electron from a 2*s* orbital than from the 2*p* orbital.

(d) The 2*s* electron is less shielded than the 2*p* electron.

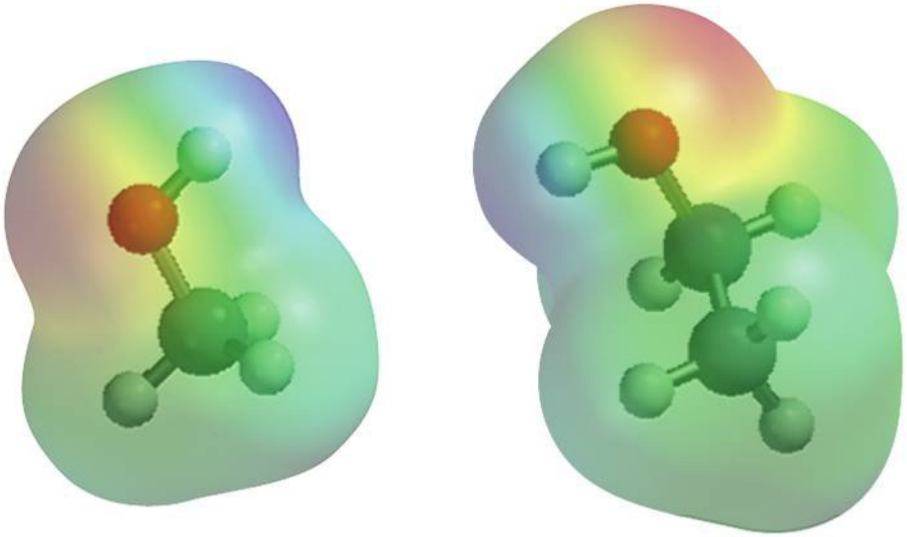
95. Describe how the ionization energies of the ions He^-, Li^-, Be^-, B^-, C^-, N^-, O^-, and F^- vary with atomic number.

96. Describe how the ionization energies of the ions Be^+, B^+, C^+, N^+, O^+, F^+, Ne^+, and Na^+ vary with atomic number.

97. Construct a concept map (see Appendix E) connecting the ideas that govern the periodic law and the periodic variation of atomic properties.

10

Chemical Bonding I: Basic Concepts



Computer-generated electrostatic potential maps of methanol (CH_3OH) and ethanol (CH_3CH_2OH). The surface encompassing each molecule shows the extent of electron charge density while the colors show the distribution of charge in the molecule. In this chapter, we study ideas that enable us to predict the geometric shapes and polarity of molecules.

10-6 Exceptions to the Octet Rule
10-7 Shapes of Molecules
10-8 Bond Order and Bond Lengths
10-9 Bond Energies

Consider all that we already know about chemical compounds. We can determine their compositions and write their formulas. We can represent the reactions of compounds by chemical equations and perform stoichiometric and thermochemical calculations based on these equations. And we can do all this without really having to consider the ultimate structure of matter—the structure of atoms and molecules. Yet the shape of a molecule—that is, the arrangement of its atoms in space—often defines its chemistry. If water had a different shape, its properties would be significantly different, and life as we know it would not be possible.

In this chapter, we will describe the interactions between atoms called *chemical bonds*. Most of the discussion centers on the Lewis theory, which provides one of the simplest methods of representing chemical bonding. We will also explore another relatively simple theory, one for predicting probable molecular shapes. Throughout the chapter, we will try to relate these theories to what is known about molecular structures from experimental measurements. In Chapter 11 we will examine the subject of chemical bonding in greater depth, and in Chapter 12 we will describe intermolecular forces—forces between molecules—and explore further the relationship between molecular shape and the properties of substances.

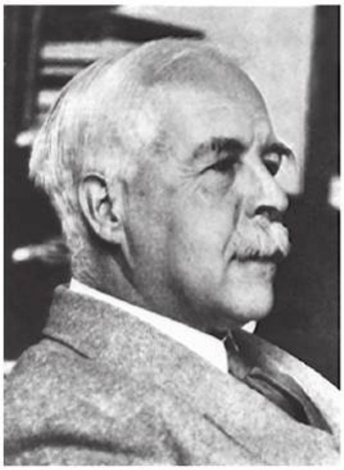
10-1 Lewis Theory: An Overview

In the period from 1916 to 1919, two Americans, G. N. Lewis and Irving Langmuir, and a German, Walther Kossel, advanced an important proposal about chemical bonding: Something unique in the electron configurations of noble gas atoms accounts for their inertness, and atoms of other elements combine with one another to acquire electron configurations like those of noble gas atoms. The theory that grew out of this model has been most closely associated with G. N. Lewis and is called the **Lewis theory**. Some fundamental ideas associated with Lewis's theory follow:

▶ Since 1962, a number of compounds of Xe and Kr have been synthesized. As we will see in this chapter, a focus on noble-gas electron configurations can still be useful, even if the idea that they confer complete inertness is invalid.

1. Electrons, especially those of the outermost (valence) electronic shell, play a fundamental role in chemical bonding.
2. In some cases, electrons are *transferred* from one atom to another. Positive and negative ions are formed and attract each other through electrostatic forces called **ionic bonds**.
3. In other cases, one or more pairs of electrons are *shared* between atoms. A bond formed by the sharing of electrons between atoms is called a **covalent bond**.
4. Electrons are transferred or shared in such a way that each atom acquires an especially stable electron configuration. Usually this is a noble gas configuration, one with eight outer-shell electrons, or an **octet**.

▶ The term *covalent* was introduced by Irving Langmuir.



▲ **Gilbert Newton Lewis (1875–1946)**
Lewis's contribution to the study of chemical bonding is evident throughout this text. Equally important, however, was his pioneering introduction of thermodynamics into chemistry.

Lewis Symbols and Lewis Structures

Lewis developed a special set of symbols for his theory. A **Lewis symbol** consists of a chemical symbol to represent the nucleus and *core* (inner-shell) *electrons* of an atom, together with dots placed around the symbol to represent the *valence* (outer-shell) *electrons*. Thus, the Lewis symbol for silicon, which has the electron configuration $[\text{Ne}]3s^2 3p^2$, is

$$\cdot\overset{\cdot}{\underset{\cdot}{\text{Si}}}\cdot$$

Electron spin had not yet been proposed when Lewis framed his theory, and so he did not show that two of the valence electrons ($3s^2$) are paired and two ($3p^2$) are unpaired. We will write Lewis symbols in the way Lewis did. We will place single dots on the sides of the symbol, up to a maximum of four. Then we will pair up dots until we reach an octet. Lewis symbols are commonly written for main-group elements but much less often for transition elements. Lewis symbols for several main-group elements are written in Example 10-1.

A **Lewis structure** is a combination of Lewis symbols that represents either the transfer or the sharing of electrons in a chemical bond.

Ionic bonding (transfer of electrons):

$$\text{Na}\times \;+\; \cdot\overset{\cdot\cdot}{\underset{\cdot\cdot}{\text{Cl}}}\!: \longrightarrow [\text{Na}]^{+}[{}_{\times}\!\cdot\overset{\cdot\cdot}{\underset{\cdot\cdot}{\text{Cl}}}\!:]^{-} \qquad (10.1)$$

Lewis symbols Lewis structure

Covalent bonding (sharing of electrons):

$$\text{H}\times \;+\; \cdot\overset{\cdot\cdot}{\underset{\cdot\cdot}{\text{Cl}}}\!: \longrightarrow \text{H}\overset{\cdot}{\times}\overset{\cdot\cdot}{\underset{\cdot\cdot}{\text{Cl}}}\!: \qquad (10.2)$$

Lewis symbols Lewis structure

EXAMPLE 10-1 Writing Lewis Symbols

Write Lewis symbols for the following elements: **(a)** N, P, As, Sb, Bi; **(b)** Al, I, Se, Ar.

Analyze

The position of the element in the periodic table determines the number of valence electrons in the Lewis symbol. For main-group elements, the number of valence electrons, and hence the number of dots appearing in a Lewis symbol, is equal to the group number for the *s*-block elements and to the group number minus 10 for the *p*-block elements.

Solve

(a) These are group 15 elements, and their atoms all have five valence electrons (ns^2np^3). The Lewis symbols all have five dots.

(b) Al is in group 13; I, in group 17; Se, in group 16; Ar, in group 18.

Assess

This example, although very straightforward, is very important. The accurate counting of valence electrons is essential for many aspects of chemical bonding.

PRACTICE EXAMPLE A: Write Lewis symbols for Mg, Ge, K, and Ne.

PRACTICE EXAMPLE B: Write the Lewis symbols expected for Sn, Br^-, Tl^+, and S^{2-}.

In these two examples, we designated the electrons involved in bond formation differently—(×) from one atom and (•) from the other. This helps to emphasize that an electron is transferred in ionic bonding and that a pair of electrons is shared in covalent bonding. Of course, it is impossible to distinguish between electrons, and henceforth we will use only dots (•) to represent electrons in Lewis structures. In Lewis theory, we use square brackets to identify ions, as we did in equation (10.1). The charge on the ion is given as a superscript.

Lewis's work dealt mostly with covalent bonding, which we will emphasize throughout this chapter. However, Lewis's ideas also apply to ionic bonding, and we briefly describe this application next.

Lewis Structures for Ionic Compounds

In Section 3-2, we learned that the formula unit of an ionic compound is the simplest electrically neutral collection of cations and anions from which the chemical formula of the compound can be established. The Lewis structure of sodium chloride (structure 10.1) represents its formula unit. For an ionic compound of a main-group element, (1) the Lewis symbol of the metal ion has no dots if all the valence electrons are lost, and (2) the ionic charges of both cations and anions are shown. These ideas are further illustrated through Example 10-2.

◀ No bond is 100% ionic. All ionic bonds have some covalent character.

EXAMPLE 10-2 Writing Lewis Structures of Ionic Compounds

Write Lewis structures for the following compounds: **(a)** BaO; **(b)** $MgCl_2$; **(c)** aluminum oxide.

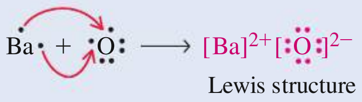
Analyze

Our approach here is to write the Lewis symbol and determine how many electrons each atom must gain or lose to acquire a noble-gas-electron configuration.

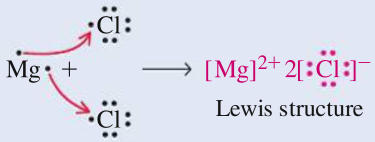
(continued)

Solve

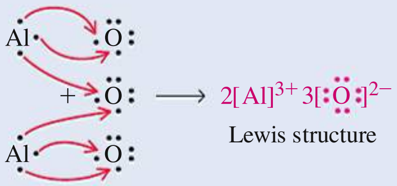
(a) Ba loses two electrons, and O gains two.



(b) A Cl atom can accept only one electron because it already has seven valence electrons. One more will give it a complete octet. Conversely, a Mg atom must lose two electrons to have the electron configuration of the noble gas neon. So two Cl atoms are required for each Mg atom.



(c) The formula of aluminum oxide follows directly from the Lewis structure. The combination of one Al atom, which loses three electrons, and one O atom, which gains two, leaves an excess of one lost electron. To match the numbers of electrons lost and gained, the formula unit must be based on *two* Al atoms and *three* O atoms.



Assess

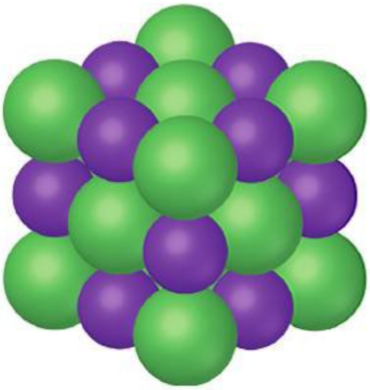
We almost never write Lewis structures for ionic compounds, except when we want to emphasize the ratio in which the ions combine. The structures of ionic compounds are much more complicated than is suggested by the Lewis structure. See, for example, the structure of NaCl shown in Figure 10-1.

PRACTICE EXAMPLE A: Write plausible Lewis structures for **(a)** Na_2S and **(b)** Mg_3N_2.

PRACTICE EXAMPLE B: Write plausible Lewis structures for **(a)** calcium iodide; **(b)** barium sulfide; **(c)** lithium oxide.

The compounds described in Example 10-2 are *binary ionic compounds* consisting of monatomic cations and monatomic anions. Commonly encountered *ternary ionic compounds* consist of monatomic and polyatomic ions. Bonding between atoms within the polyatomic ions is covalent. Some ternary ionic compounds are considered later in the chapter.

With the exception of ion pairs, such as (Na^+Cl^-), that may be found in the *gaseous* state, formula units of solid ionic compounds do not exist as separate entities. Instead, each cation is surrounded by anions and each anion by cations. These very large numbers of ions are arranged in an orderly network called an *ionic crystal* (Fig. 10-1). Ionic crystal structures and the energy changes accompanying the formation of ionic crystals are described in Chapter 12.



▲ FIGURE 10-1
Portion of an ionic crystal
This structure of alternating Na^+ and Cl^- ions extends in all directions and involves countless numbers of ions.

10-1 CONCEPT ASSESSMENT

How many valence electrons do the Lewis symbols for the elements in group 16 have? Which of the following are correct Lewis symbols for sulfur?

10-2 Covalent Bonding: An Introduction

A chlorine atom shows a tendency to gain an electron, as indicated by its electron affinity (-349 kJ/mol). From which atom, sodium or hydrogen, can the electron most readily be extracted? Neither atom gives up an electron freely, but the energy required to extract an electron from Na ($I_1 = 496$ kJ/mol) is much smaller than that for H ($I_1 = 1312$ kJ/mol). In Chapter 9 we learned that the lower its ionization energy, the more metallic an element is; sodium is much more metallic than hydrogen (recall Figure 9-12). In fact, hydrogen is considered to be a nonmetal. A hydrogen atom in the gaseous state does not give up an electron to another nonmetal atom. Bonding between a hydrogen atom and a chlorine atom involves the sharing of electrons, which leads to a *covalent bond*.

To emphasize the sharing of electrons, let us think of the Lewis structure of HCl in this manner.

The broken circles represent the outermost electron shells of the bonded atoms. The number of dots lying on or within each circle represents the effective number of electrons in each valence shell. The H atom has two dots, as in the electron configuration of He. The Cl atom has eight dots, corresponding to the outer-shell configuration of Ar. Note that we counted the two electrons between H and Cl (:) *twice*. These two electrons are shared by the H and Cl atoms. This shared pair of electrons constitutes the covalent bond. Written below are two additional Lewis structures of simple molecules.

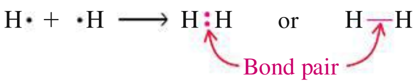
Water

Dichlorine monoxide

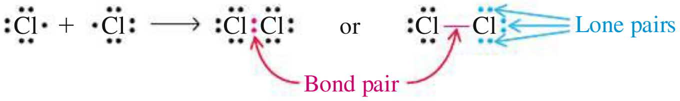
◀ The Lewis structures for H_2O and Cl_2O suggest that these molecules have a linear shape. They do not. Lewis theory by itself does not address the question of molecular shape (see Section 10-7).

As was the case for Cl in HCl, the O atom in the Lewis structure of H_2O and in Cl_2O is surrounded by eight electrons (when the bond-pair electrons are double counted). In attaining these eight electrons, the O atom conforms to the **octet rule**—a requirement of eight valence-shell electrons for the atoms in a Lewis structure. Note, however, that the H atom is an exception to this rule. The H atom can accommodate only two valence-shell electrons.

Lewis theory helps us to understand why elemental hydrogen and chlorine exist as diatomic molecules, H_2 and Cl_2. In each case, a pair of electrons is shared between the two atoms. The sharing of a single pair of electrons between bonded atoms produces a **single covalent bond**. To underscore the importance of electron pairs in the Lewis theory the term **bond pair** applies to a pair of electrons in a covalent bond, while **lone pair** applies to electron pairs that are not involved in bonding. Also, in writing Lewis structures it is customary to replace bond pairs with lines (—). These features are shown in the following Lewis structures.



(10.3)



(10.4)

Coordinate Covalent Bonds

The Lewis theory of bonding describes a covalent bond as the sharing of a pair of electrons, but this does not necessarily mean that each atom contributes an electron to the bond. A covalent bond in which a single atom contributes both of the electrons to a shared pair is called a **coordinate covalent bond**.

EXAMPLE 10-3 Writing Simple Lewis Structures

Write a Lewis structure for the ammonia molecule, NH_3.

Analyze

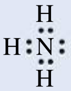
To write a Lewis structure we must know the number of valence electrons associated with each atom.

Solve

The valence electrons can then be represented in the Lewis symbols, as shown here.

$$\mathrm{H\cdot}\quad \mathrm{H\cdot}\quad \mathrm{H\cdot}\quad \cdot\underset{\cdot}{\dot{\mathrm{N}}}:$$

Now we can assemble one N and three H atoms into a structure that gives the N atom a valence-shell octet and each of the H atoms two valence electrons (producing the electron configuration of He).



$$\mathrm{H}:\overset{\mathrm{H}}{\underset{\mathrm{H}}{\mathrm{N}}}:$$

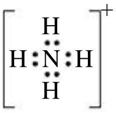
Assess

The application of the octet rule has led us to the correct Lewis structure for ammonia, but, as we will see later in this text, many molecules do not obey the octet rule.

PRACTICE EXAMPLE A: Write Lewis structures for Br_2, CH_4, and HOCl.

PRACTICE EXAMPLE B: Write Lewis structures for NI_3, N_2H_4, and C_2H_6.

If we attempt to attach a fourth H atom to the Lewis structure of NH_3 shown in Example 10-3, we encounter a difficulty. The electron brought by the fourth H atom would raise the total number of valence electrons around the N atom to *nine*, so there would no longer be an octet. The *molecule* NH_4 does not form, but the *ammonium ion*, NH_4^+, does, as suggested in Figure 10-2. That is, the lone pair of electrons on a NH_3 molecule extracts an H atom from a HCl molecule, and the electrons in the H—Cl bond remain on the Cl atom. The result is equivalent to a H^+ ion joining with the NH_3 molecule to form the NH_4^+ ion,

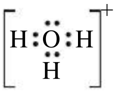


$$\left[\mathrm{H}:\overset{\mathrm{H}}{\underset{\mathrm{H}}{\mathrm{N}}}:\mathrm{H}\right]^+ \tag{10.5}$$

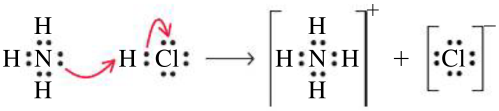
As shown in Figure 10-2, the electron pair from the H — Cl bond remains on the Cl atom, converting it to a Cl^- ion.

The bond formed between the N atom of NH_3 and the H^+ ion in structure (10.5) is a *coordinate covalent bond*. It is important to note, however, that once the bond has formed, it is impossible to say which of the four N—H bonds is the coordinate covalent bond. Thus, a coordinate covalent bond is indistinguishable from a regular covalent bond.

Another example of coordinate covalent bonding is found in the familiar hydronium ion.



$$\left[\mathrm{H}:\underset{\mathrm{H}}{\ddot{\mathrm{O}}}:\mathrm{H}\right]^+ \tag{10.6}$$



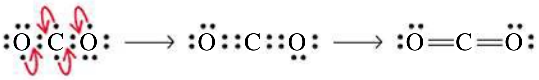
▶ FIGURE 10-2
Formation of the ammonium ion, NH_4^+
The H atom of HCl leaves its electron with the Cl atom and, as H^+, attaches itself to the NH_3 molecule through the lone-pair electrons on the N atom. The ions NH_4^+ and Cl^- are formed.

Multiple Covalent Bonds

In the preceding description of the Lewis model for covalent chemical bonding, we have used a single pair of electrons between two atoms to describe a single covalent bond. Often, however, more than one pair of electrons must be shared if an atom is to attain an octet (noble gas electron configuration). CO_2 and N_2 are two molecules in which atoms share more than one pair of electrons.

First, let's apply the ideas about Lewis structures to CO_2. From the Lewis symbols, we see that the C atom can share a valence electron with each O atom, thus forming two carbon-to-oxygen single bonds.

But this leaves the C atom and both O atoms still shy of an octet. The problem is solved by shifting the unpaired electrons into the region of the bond, as indicated by the red arrows.



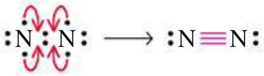
(10.7)

In Lewis structure (10.7), the bonded atoms are seen to share *two* pairs of electrons (a total of four electrons) between them—a **double covalent bond** (═).

Now let's try our hand at writing a Lewis structure for the N_2 molecule. Our first attempt might again involve a single covalent bond and the incorrect structure shown below.

(*Incorrect*)

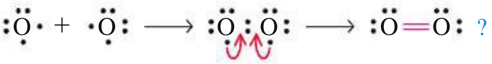
Each N atom appears to have only six outer-shell electrons, not the expected eight. The situation can be corrected by bringing the four unpaired electrons into the region between the N atoms and using them for additional bond pairs. In all, we now show the sharing of *three* pairs of electrons between the N atoms. The bond between the N atoms in N_2 is a **triple covalent bond** (≡). Double and triple covalent bonds are known as **multiple covalent bonds**.



(10.8)

The triple covalent bond in N_2 is a very strong bond that is difficult to break in a chemical reaction. The unusual strength of this bond makes $N_2(g)$ quite inert. As a result, $N_2(g)$ coexists with $O_2(g)$ in the atmosphere and forms oxides of nitrogen only in trace amounts at high temperatures. The lack of reactivity of N_2 with O_2 is an essential condition for life on Earth. The inertness of $N_2(g)$ also makes it difficult to synthesize nitrogen compounds.

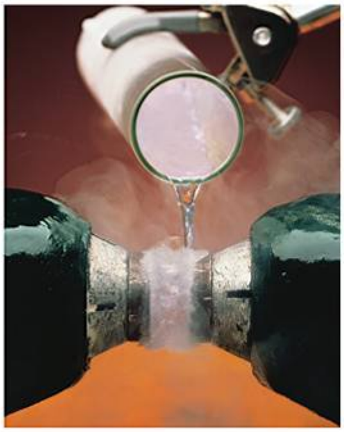
Another molecule whose Lewis structure features a multiple bond is O_2, which has a double bond.



(10.9)

The blue question mark suggests that there is some doubt about the validity of structure (10.9), and the source of the doubt is illustrated in Figure 10-3. The structure fails to account for the *paramagnetism* of oxygen—the O_2 molecule must have *unpaired* electrons. Unfortunately, no completely satisfactory Lewis structure is possible for O_2, but in Chapter 11, bonding in the O_2 molecule is described in a way that accounts for both the double bond and the observed paramagnetism.

We could continue applying ideas introduced in this section, but our ability to write plausible Lewis structures will be greatly aided by a couple of new ideas that we introduce in Section 10-3.



▲ FIGURE 10-3
Paramagnetism of oxygen
Liquid oxygen is attracted into the magnetic field of a large magnet.

KEEP IN MIND

that merely being able to write a plausible Lewis structure does not prove that it is the correct electronic structure. Proof can come only through confirming experimental evidence.

10-2 CONCEPT ASSESSMENT

What types of bonds can be used to describe the chemical bonds in BF_4^-?

10-3 CONCEPT ASSESSMENT

In which groups of the periodic table are the elements most likely to use multiple bonds?

10-3 Polar Covalent Bonds and Electrostatic Potential Maps

We have introduced ionic and covalent bonds as though they are of two distinctly different types: ionic bonds involving a *complete transfer* of electrons and covalent bonds involving an *equal sharing* of electron pairs. Such is not the case, however, and most chemical bonds fall between the two extremes of 100% ionic and 100% covalent. A covalent bond in which electrons are not shared equally between two atoms is called a **polar covalent bond**. In such a bond, electrons are displaced toward the more nonmetallic element. The unequal sharing of the electrons leads to a partial negative charge on the more nonmetallic element, signified by $\delta-$, and a corresponding partial positive charge on the more metallic element, designated by $\delta+$. Thus we can represent the polar bond in HCl by a Lewis structure in which the partial charges $\delta+$ and $\delta-$ indicate that the bond pair of electrons lies closer to the Cl than to the H.

$$^{\delta+}\mathrm{H}\;:\!\overset{\cdot\cdot}{\underset{\cdot\cdot}{\mathrm{Cl}}}\!:^{\delta-}$$

The advent of inexpensive, fast computers has allowed chemists to develop methods for displaying the electron distribution within molecules. This distribution is obtained, in principle, by solving the Schrödinger equation for a molecule. Although the solution can be obtained only by using approximate methods, these methods provide an **electrostatic potential map**, a way to visualize the charge distribution within a molecule.

Before discussing these maps let us first review the notion of electron density, or charge density, introduced in Chapter 8. There we saw that the behavior of electrons in atoms can be described by mathematical functions called orbitals. The probability of finding an electron at some point in the three-dimensional region associated with an orbital is related to the square of an atomic orbital function. Typically, we refer to the region encompassing 95% of the probability of finding the electron as the shape of the orbital. In a similar way we can map the total electron density throughout a molecule, that is, not just the density of a single orbital. The electron density surface that encompasses 95% of the charge density in ammonia is depicted in Figure 10-4.

The *electrostatic potential* is the work done in moving a unit of positive charge at a constant speed from one region of a molecule to another. The electrostatic potential map is obtained by hypothetically probing an electron density surface with a positive point charge. The positive point charge will be attracted to an electron-rich region—a region of excess negative charge when all the charges of the nuclei and electrons have been taken into account—and the electrostatic potential will be *negative*. Conversely, if the point charge is placed in an electron-poor region, a region of excess positive charge, the positive point charge will be repelled, and the electrostatic potential will be *positive*. The procedure for making an electrostatic potential map is illustrated in Figure 10-4, which shows the distribution of electron density in ammonia.

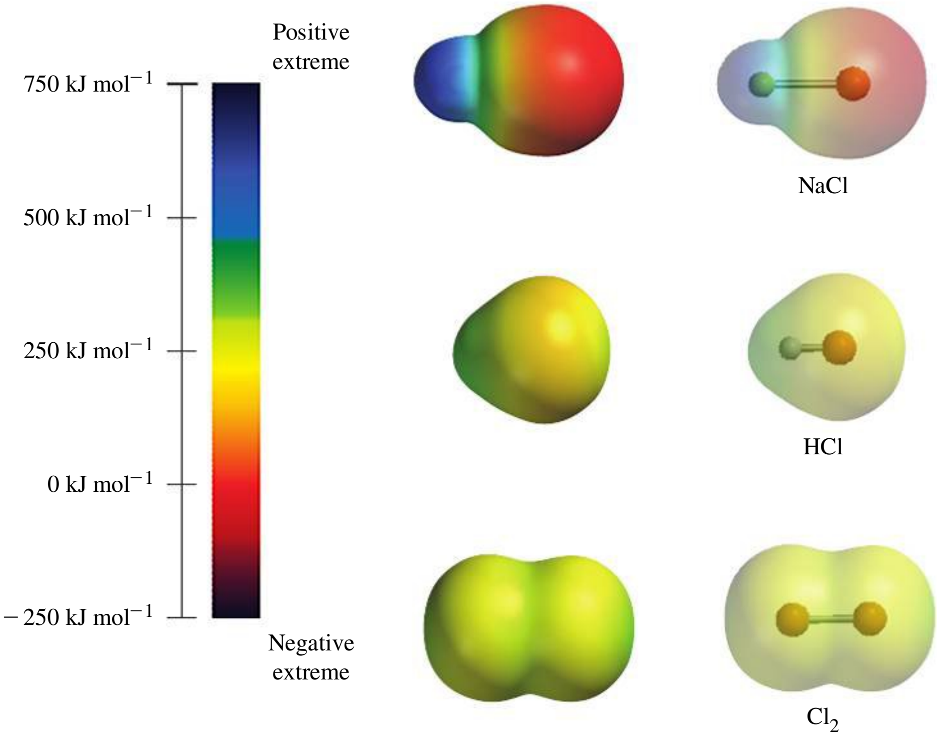
◀ FIGURE 10-4
Determination of the electrostatic potential map for ammonia
The electrostatic potential at any point on the charge density surface of a molecule is defined as the change in energy that occurs when a unit positive charge is brought to this point, starting from another point that is infinitely far removed from the molecule. The surface encompassing the ammonia molecule is analogous to the 95% surface of electron charge density for atomic orbitals discussed in Chapter 8. The electrostatic potential map gives information about the distribution of electron charge within this surface.

An electrostatic potential map gives information about the distribution of electron charge in a molecule. For example, in a neutral molecule, if the potential at a point is positive, it is likely that an atom at this point carries a net positive charge. An arbitrary "rainbow" color scheme is adopted in the display of an electrostatic potential map. Red, the low-energy end of the spectrum, is used for regions of the most negative electrostatic potential, and blue is used to color regions of the most positive electrostatic potential. Intermediate colors represent intermediate values of the electrostatic potential. Thus, the potential increases from red through yellow to blue, as seen in the scale in Figure 10-5. For example,

◀ Electrostatic potential is the work done in moving a unit of positive charge at a constant speed from one region of a molecule to another.



Positive extreme
750 kJ mol^{-1}
500 kJ mol^{-1}
250 kJ mol^{-1}
0 kJ mol^{-1}
-250 kJ mol^{-1}
Negative extreme
NaCl
HCl
Cl_2

◀ FIGURE 10-5
The electrostatic potential maps for sodium chloride, hydrogen chloride, and chlorine
The dark red and dark blue on the electrostatic potential map correspond to the extremes of the electrostatic potential, negative to positive, for the particular molecule for which the map is calculated. To get a reliable comparison of different molecules, the values of the extremes in electrostatic potential (in kJ mol^{-1}) must be the same for all of the molecules compared. In the maps shown here the range is -250 to 750 kJ mol^{-1}.

the blue-green color surrounding the hydrogen atoms in Figure 10-4 suggests that they carry a slight positive charge. The nitrogen atom, being closest to the red region, carries a net negative charge.

Let us now look at the computed electrostatic potential maps for NaCl, Cl_2, and HCl (Fig. 10-5). We see that Cl_2 has a uniform distribution of electron charge density as depicted by the uniform color distribution in the electrostatic potential map. This is typical for a nonpolar covalent bond and occurs in all diatomic molecules containing identical atoms. The sodium chloride molecule, conversely, exhibits a highly nonuniform distribution of electron charge density. The sodium atom is almost exclusively in the blue extreme of positive charge and the chlorine in the red extreme of negative charge. This electrostatic potential map is typical of an ionic bond, yet it is clear from the map that the transfer of electron density from the sodium atom to the chlorine atom is not complete. That is, the NaCl bond is not completely ionic. Experiments show that the bond is only about 80% ionic. The molecule HCl also has an unsymmetrical distribution of electron charge density, as indicated by the gradation of color in the electrostatic potential map. Note, however, that in this case the chlorine atom is not completely in the extreme dark red corresponding to a large negative charge. Instead, it is in the orange-red region indicating a partial negative charge. Correspondingly, the hydrogen atom has a partial positive charge, as indicated by the pale blue. The electrostatic potential map clearly depicts the polar nature of the bond in HCl.

Electronegativity

We expect the H—Cl bond to be polar because the Cl atom has a greater affinity for electrons than does the H atom. Electron affinity is an atomic property, however, and more meaningful predictions about bond polarities are those based on a molecular property, one that relates to the ability of atoms to lose or gain electrons when they are part of a molecule rather than isolated from other atoms.

Electronegativity (EN) describes an atom's ability to compete for electrons with other atoms to which it is bonded. As such, electronegativity is related to ionization energy (I) and electron affinity (EA). To see how they are related consider the reaction between two hypothetical elements, A and B, which could give the products A^+B^- or A^-B^+. We represent these two reactions by the expressions

$$A + B \longrightarrow A^+B^- \qquad \Delta E_1 = (I_A + EA_B) \tag{10.10}$$

$$A + B \longrightarrow A^-B^+ \qquad \Delta E_2 = (I_B + EA_A) \tag{10.11}$$

If the bonding electrons are shared approximately equally in these hypothetic structures, we would expect that $\Delta E_1 = \Delta E_2$ because neither extreme (A^+B^- or A^-B^+) is favored. If we make the assumption that the resultant bond is nonpolar, then

$$(I_A + EA_B) = (I_B + EA_A)$$

which gives, after collecting terms for each atom,

$$(I_A - EA_A) = (I_B - EA_B) \tag{10.12}$$

Equation (10.12) tells us that a nonpolar bond will result when the difference between the ionization energy and the electron affinity is the same for both atoms involved in the bond. The quantity $(I - EA)$ provides a measure of the ability of an atom to attract electrons (or electron charge density) to itself relative to some other atom. Thus it is related to the electronegativity of the atom.

$$EN_A \propto (I_A - EA_A)$$

An element with a high ionization energy and an electron affinity that is large and negative, such as fluorine, will have a large electronegativity

▲ FIGURE 10-6
Electronegativities of the elements
As a general rule, electronegativities *decrease* from *top to bottom* in a group and *increase* from *left to right* in a period of elements. The values are from L. Pauling, *The Nature of the Chemical Bond*, 3rd ed., Cornell University, Ithaca, NY, 1960, page 93. Values may be somewhat different when based on other electronegativity scales.

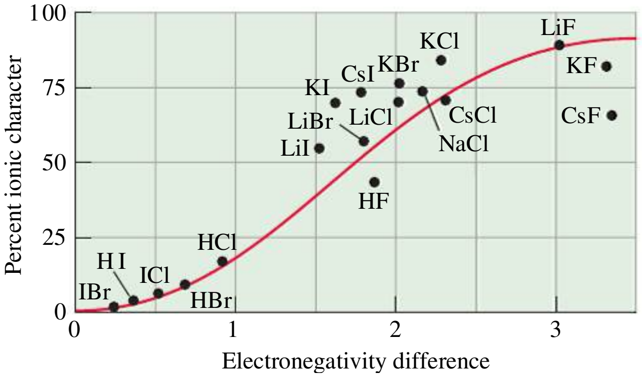
relative to an atom with a low ionization energy and a small electron affinity, such as sodium.

There are several methods for converting qualitative comparisons to actual numerical values of the electronegativities of the elements. One widely used electronegativity scale, with values given in Figure 10-6, is that devised by Linus Pauling (1901–1994). Pauling's EN values range from about 0.7 to 4.0. In general, the lower its EN, the more metallic the element is, and the higher the EN, the more nonmetallic it is. From Figure 10-6 we also see that electronegativity decreases from top to bottom in a group and increases from left to right in a period of the periodic table. These are the expected trends when we interpret electronegativity in terms of the quantity $(I - EA)$. That is, as the ionization energy (I) increases across the period we expect the electronegativity to increase. The distinction between electron affinity and electronegativity is clearly seen when we consider the electron affinities of F $(-328\ \mathrm{kJ\ mol^{-1}})$ and chlorine $(-349\ \mathrm{kJ\ mol^{-1}})$: Although the electron affinity of Cl $(-349\ \mathrm{kJ/mol})$ is somewhat more negative than that of F $(-328\ \mathrm{kJ/mol})$, the EN of Cl (3.0) is significantly lower than that of F (4.0) because of the decreased ionization energy of chlorine (1251 kJ/mol) relative to fluorine (1681 kJ/mol).

10-4 CONCEPT ASSESSMENT

With the aid of only a periodic table, decide which is the most electronegative atom of each of the following sets of elements: **(a)** As, Se, Br, I; **(b)** Li, Be, Rb, Sr; **(c)** Ge, As, P, Sn.

Electronegativity values allow an insight into the amount of polar character in a covalent bond based on **electronegativity difference, ΔEN**—the absolute value of the difference in EN values of the bonded atoms. If ΔEN for two



▶ FIGURE 10-7
Percent ionic character of a chemical bond as a function of electronegativity difference

atoms is very small, the bond between them is essentially covalent. If ΔEN is large, the bond is essentially ionic. For intermediate values of ΔEN, the bond is described as polar covalent. A useful rough relationship between ΔEN and percent ionic character of a bond is presented in Figure 10-7.

Large EN differences are found between the more metallic and the more nonmetallic elements. Combinations of these elements are expected to produce bonds that are essentially ionic. Small EN differences are expected for two nonmetal atoms, and the bond between them should be essentially covalent. Thus, even without a compilation of EN values at hand, you should be able to predict the essential character of a bond between two atoms. Simply assess the metallic/nonmetallic characters of the bonded elements from the periodic table (recall Figure 9-12).

▶ Although Figure 10-7 suggests that the bond between two identical metal atoms should be covalent [as it is in $Li_2(g)$, for example], in *solid* metals, where bonding extends throughout a network of many, many atoms, the bonding is of a type called *metallic* (explored in the next chapter).

EXAMPLE 10-4 Assessing Electronegativity Differences and the Polarity of Bonds

(a) Which bond is more polar, H—Cl or H—O?
(b) What is the percent ionic character of each of these bonds?

Analyze

To decide which bond is more polar, look up EN values for H, Cl, and O in Figure 10-6, and then compute electronegativity differences, ΔEN, for H—Cl and H—O bonds. The greater the electronegativity difference, the more polar the bond. To determine the percentage ionic character, we use the curve in Figure 10-7.

Solve

(a) $\text{EN}_\text{H} = 2.1$; $\text{EN}_\text{Cl} = 3.0$; $\text{EN}_\text{O} = 3.5$. For the H—Cl bond, $\Delta\text{EN} = 3.0 - 2.1 = 0.9$. For the H—O bond, $\Delta\text{EN} = 3.5 - 2.1 = 1.4$. Because its ΔEN is somewhat greater, we expect the H—O bond to be the more polar bond.

(b) Determine the percent ionic character from Figure 10-7.

H—Cl bond: $\Delta\text{EN} = 0.9$ ≈20% ionic
H—O bond: $\Delta\text{EN} = 1.4$ ≈35% ionic

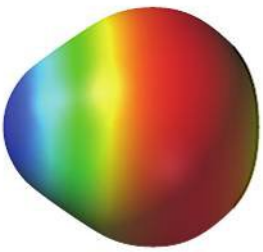
Assess

In this example, we used EN values to decide which of two bonds is more polar. EN values can also be used to decide which end of a given bond will be slightly negative. For example, because EN_Cl is greater than EN_H, we conclude that the Cl end of the H—Cl bond will be slightly negative; thus, the H end will be slightly positive.

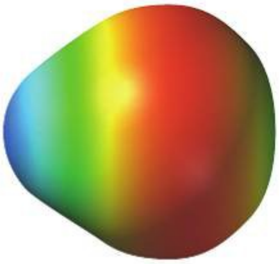
PRACTICE EXAMPLE A: Which of the following bonds are the most polar, that is, have the greatest ionic character: H—Br, N—H, N—O, P—Cl?

PRACTICE EXAMPLE B: Which is the most polar bond: C—S, C—P, P—O, or O—F?

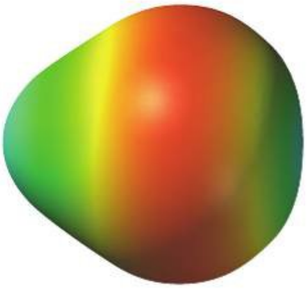
To illustrate the variation of bond polarity with electronegativity using electrostatic potential maps, consider the electrostatic potential maps for HCl, HBr and HI displayed below.



HCl



HBr



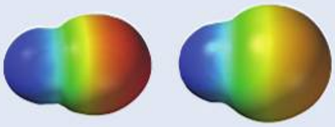
HI

The gradation of the charge on the H atom ranges from quite positive in HCl to less positive in HBr and HI, as is seen in the gradation of color on the H atom from dark blue to pale blue. This trend of decreasing charge separation in these three molecules corresponds to the decrease in electronegativity of the halogen atoms from Cl to Br to I. Correspondingly, the halogen atom becomes less red—signifying a decreasing negative charge in going from chlorine to iodine. Electrostatic potential maps are a powerful way of displaying the variation of polarity within a group of related molecules. We will use computed electrostatic potential maps later in this chapter and in subsequent chapters, whenever charge separation within a molecule contributes significantly to understanding the topic at hand.

◀ You may have noticed that the electrostatic potential map shown here for HCl has a different range of colors than the one shown in Figure 10-5. In Fig. 10-5, the electrostatic potential map for NaCl shows the greatest range of colors because, of the molecules shown there, NaCl has the greatest ionic character. Here, the electrostatic potential map for HCl shows the greatest range of colors because, compared to HBr and HI, HCl has the greatest ionic character. (See Fig. 10-7.)

EXAMPLE 10-5 Identifying a Molecular Structure Using Electronegativity and Electrostatic Potential Maps

Two electrostatic potential maps are shown below. One corresponds to NaF and the other to NaH. Which map corresponds to which molecule?



Analyze

Look up EN values for H, F, and Na in Figure 10-6, and then compute electronegativity differences for NaF and NaH bonds. The bond with the greatest electronegativity difference will be more polar, and its electrostatic potential map will show a greater range of colors.

Solve

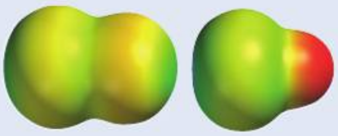
$\mathrm{EN_H} = 2.1$; $\mathrm{EN_{Na}} = 0.9$; $\mathrm{EN_F} = 4.0$. For the H—Na bond, $\Delta\mathrm{EN} = 2.1 - 0.9 = 1.2$. For the F—Na bond, $\Delta\mathrm{EN} = 4.0 - 0.9 = 3.1$. Because ΔEN for NaF is greater, we expect the F—Na bond to be the more polar bond. We conclude that the electrostatic potential map on the left represents NaF.

Assess

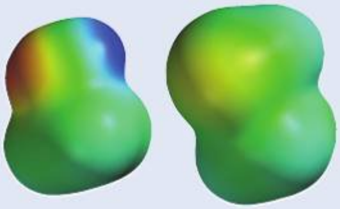
It may seem surprising that, in the electrostatic potential maps shown for NaF and NaH, the H "atom" in NaH appears larger than the F "atom" in NaF. Bear in mind that the bonds in both molecules have significant ionic character, and so, when comparing the electrostatic potentials maps for these two molecules, it is more appropriate to think in terms of F^- and H^- ions. Various studies suggest that the NaH bond is probably between 50% and 80% ionic and that the NaF bond is about 90% ionic. Studies on solid NaH suggest that the radius of a H^- ion is somewhere between that of F^- (133 pm) and that of Cl^- (181 pm).

(continued)

PRACTICE EXAMPLE A: Which of the following electrostatic potential maps corresponds to IF, and which to IBr?



PRACTICE EXAMPLE B: Which of the following electrostatic potential maps corresponds to CH_3OH, and which to CH_3SH?



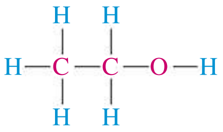
10-4 Writing Lewis Structures

In this section we combine the ideas introduced in the preceding three sections with a few new concepts to write a variety of Lewis structures. Let us begin with a reminder of some of the essential features of Lewis structures that we have already encountered.

- *All* the valence electrons of the atoms in a Lewis structure must appear in the structure.
- *Usually*, all the electrons in a Lewis structure are paired.
- *Usually*, each atom acquires an outer-shell octet of electrons. Hydrogen, however, is limited to two outer-shell electrons.
- *Sometimes*, multiple covalent bonds (double or triple bonds) are needed. Multiple covalent bonds are formed most readily by C, N, O, P, and S atoms.

Skeletal Structures

The usual starting point in writing a Lewis structure is to designate the **skeletal structure**—all the atoms in the structure arranged in the order in which they are bonded to one another. In a skeletal structure with more than two atoms, we generally need to distinguish between central and terminal atoms. A **central atom** is bonded to two or more atoms, and a **terminal atom** is bonded to just one other atom. As an example, consider ethanol, CH_3CH_2OH. Its skeletal structure is the same as the following structural formula. In this structure, the *central atoms*—both C atoms and the O atom—are printed in red. The *terminal atoms*—all six H atoms—are printed in blue.

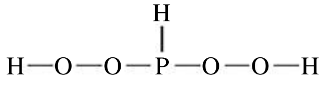


$$\begin{array}{ccccccc} & & H & & H & & \\ & & | & & | & & \\ H & - & C & - & C & - & O - H \\ & & | & & | & & \\ & & H & & H & & \end{array} \qquad (10.13)$$

Here are a few additional facts about central atoms, terminal atoms, and skeletal structures.

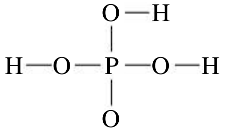
- *Hydrogen atoms are always terminal atoms.* This is because an H atom can accommodate only two electrons in its valence shell, so it can form only one bond to another atom. (An interesting and rare exception occurs in some boron–hydrogen compounds.)

- *Central atoms are generally those with the lowest electronegativity.* In the skeletal structure (10.13), the atoms of lowest electronegativity (EN = 2.1) happen to be H atoms, but as noted above, H atoms can be only terminal atoms. Next lowest in electronegativity (EN = 2.5) are the C atoms, and these are central atoms. The O atom has the highest electronegativity (3.5) but nevertheless is also a central atom. For O to be a terminal atom in structure (10.13) would require it to exchange places with an H atom, but this would make the H atom a central atom and that is not possible. The chief cases where O atoms are central atoms are in structures with a *peroxo* linkage (—O—O—) or a *hydroxy* group (—O—H). Otherwise, expect an O atom to be a *terminal* atom.
- *Carbon atoms are always central atoms.* This is a useful fact to keep in mind when writing Lewis structures of organic molecules.
- Except for the very large number of chain-like organic molecules, *molecules and polyatomic ions generally have compact, symmetrical structures.* Thus, of the two skeletal structures below, the more compact structure on the right is the one actually observed for phosphoric acid, H_3PO_4.



$$\mathrm{H{-}O{-}O{-}\overset{\displaystyle H}{\overset{|}{P}}{-}O{-}O{-}H}$$

(*Incorrect*)



$$\mathrm{H{-}O{-}\underset{\displaystyle O}{\underset{|}{\overset{\displaystyle O{-}H}{\overset{|}{P}}}}{-}O{-}H}$$

(*Correct*)

A Strategy for Writing Lewis Structures

At this point, let us incorporate a number of the ideas that we have considered so far into a specific approach to writing Lewis structures. This strategy is designed to give you a place to begin, as well as consecutive steps to follow to achieve a plausible Lewis structure.

1. Determine the total number of valence electrons that must appear in the structure.

   Examples: In the *molecule* CH_3CH_2OH, there are *4* valence electrons for each C atom, or *8* for the two C atoms; *1* for each H atom, or *6* for the six H atoms; and *6* for the lone O atom. The total number of valence electrons in the Lewis structure of CH_3CH_2OH is

   $$8 + 6 + 6 = 20$$

   In the *polyatomic ion* PO_4^{3-}, there are *5* valence electrons for the P atom and *6* for each O atom, or *24* for all four O atoms. To produce the charge of 3−, an additional *3* valence electrons must be brought into the structure. The total number of valence electrons in the Lewis structure of PO_4^{3-} is

   $$5 + 24 + 3 = 32$$

   In the *polyatomic ion* NH_4^+, there are *5* valence electrons for the N atom and *1* for each H atom, or *4* for all four H atoms. To account for the charge of 1+, one of the electrons must be *lost*. The total number of valence electrons in NH_4^+ is

   $$5 + 4 - 1 = 8$$

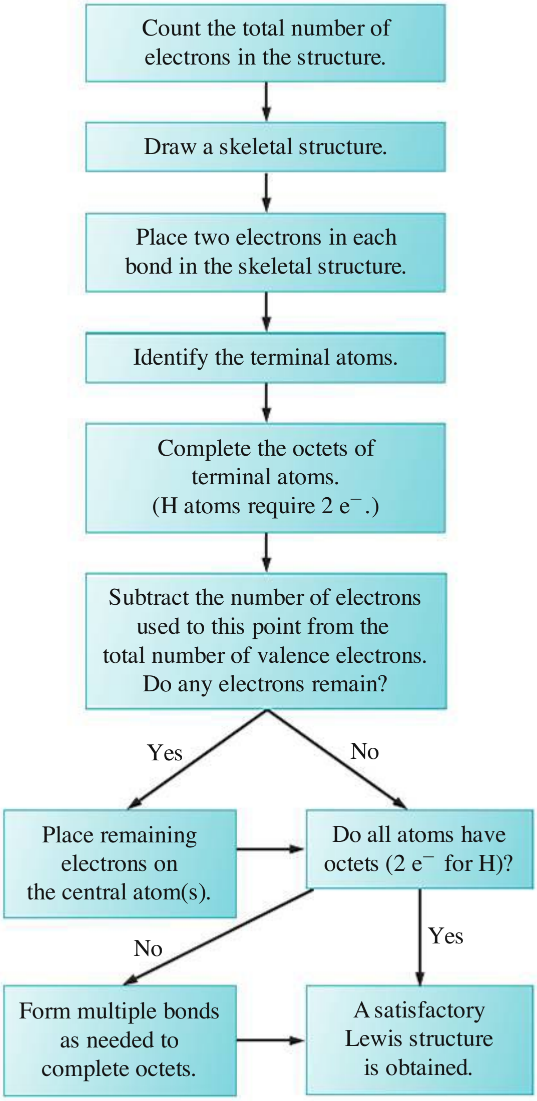
2. Identify the central atoms(s) and terminal atoms.
3. Write a plausible skeletal structure. Join the atoms in the skeletal structure by *single* covalent bonds (single dashes, representing two electrons each).
4. For each bond in the skeletal structure, subtract *two* from the total number of valence electrons.
5. With the valence electrons remaining, *first* complete the octets of the terminal atoms. *Then*, to the extent possible, complete the octets of the central

atom(s). If there are just enough valence electrons to complete octets for all the atoms, the structure at this point is a satisfactory Lewis structure.

6. If one or more central atoms are left with an incomplete octet after step 5, move lone-pair electrons from one or more terminal atoms to form *multiple* covalent bonds to central atoms. Do this to the extent necessary to give all atoms complete octets, thereby producing a satisfactory Lewis structure.

Figure 10-8 summarizes this procedure for writing Lewis structures.

▶ It requires a lot of practice to become proficient at writing Lewis structures. Begin by writing structures of molecules that have only one central atom before trying to write the structures of more complicated molecules.



Count the total number of electrons in the structure.
Draw a skeletal structure.
Place two electrons in each bond in the skeletal structure.
Identify the terminal atoms.
Complete the octets of terminal atoms. (H atoms require 2 e⁻.)
Subtract the number of electrons used to this point from the total number of valence electrons. Do any electrons remain?
Yes
No
Place remaining electrons on the central atom(s).
Do all atoms have octets (2 e⁻ for H)?
No
Yes
Form multiple bonds as needed to complete octets.
A satisfactory Lewis structure is obtained.

▶ FIGURE 10-8
Summary scheme for drawing Lewis structures

EXAMPLE 10-6 Applying the General Strategy for Writing Lewis Structures

Write a plausible Lewis structure for *cyanogen*, C_2N_2, a poisonous gas used as a fumigant and rocket propellant.

Analyze

Here, we apply the scheme for constructing Lewis structures (Fig. 10-8).

Solve

Step 1. Determine the total number of valence electrons. Each of the two C atoms (group 14) has *four* valence electrons, and each of the two N atoms (group 15) has *five*. The total number of valence electrons is $4 + 4 + 5 + 5 = 18$.

Step 2. Identify the central atom(s) and terminal atoms. Because the C atoms have a lower electronegativity (2.5) than do the N atoms (3.0), C atoms are central atoms, and N atoms are terminal atoms.

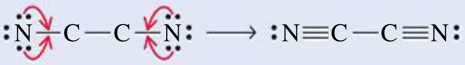
Step 3. Write a plausible skeletal structure by joining atoms through *single* covalent bonds.

$$\mathrm{N{-}C{-}C{-}N}$$

Step 4. Subtract *two* electrons for each bond in the skeletal structure. The three bonds in this structure account for *6* of the 18 valence electrons. This leaves *12* valence electrons to be assigned.

Step 5. Complete octets for the terminal N atoms, and to the extent possible, the central C atoms. The remaining *12* valence electrons are sufficient only to complete the octets of the N atoms.

Step 6. Move lone pairs of electrons from the terminal N atoms to form multiple bonds to the central C atoms. Each C atom has only four electrons in its valence shell and needs four more to complete an octet. Thus, each C atom requires two additional pairs of electrons, which it acquires if we move two lone pairs from each N atom into its bond with a C atom, as shown below.



Assess

The construction of correct Lewis structures is an important skill that all chemists have to master. It is imperative to be able to apply the scheme without referring to the steps on page 409 or in Figure 10-8.

PRACTICE EXAMPLE A: Write plausible Lewis structures for **(a)** CS_2, **(b)** HCN, and **(c)** $COCl_2$.

PRACTICE EXAMPLE B: Write plausible Lewis structures for **(a)** formic acid, HCOOH, and **(b)** acetaldehyde, CH_3CHO.

EXAMPLE 10-7 Writing a Lewis Structure for a Polyatomic Ion

Write the Lewis structure for the *nitronium* ion, NO_2^+.

Analyze

Again, we use the strategy illustrated in Figure 10-8.

Solve

Step 1. Determine the total number of valence electrons. The N atom (group 15) has *five* valence electrons, and each of the two O atoms (group 16) has *six*. However, *one* valence electron must be removed to produce the charge of 1+.

The total number of valence electrons is $5 + 6 + 6 - 1 = 16$

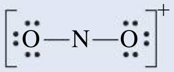
Step 2. Identify the central atom(s) and terminal atoms. The N atom has a lower electronegativity (3.0) than the O atoms (3.5). N is the central atom, and the O atoms are the terminal atoms.

Step 3. Write a plausible skeletal structure by joining atoms through *single* covalent bonds.

$$\mathrm{O{-}N{-}O}$$

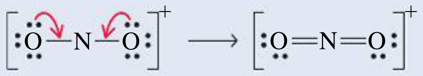
Step 4. Subtract *two* electrons for each bond in the skeletal structure. The two bonds in this structure account for *4* of the 16 valence electrons. This leaves *12* valence electrons to be assigned.

Step 5. Complete octets for the terminal O atoms, and to the extent possible, the central N atom. The remaining *12* valence electrons are sufficient only to complete the octets of the O atoms.



(continued)

Step 6. Move lone pairs of electrons from the terminal O atoms to form multiple bonds to the central N atom. The N atom has only four electrons in its valence shell and needs four more to complete an octet. Thus, the N atom requires two additional pairs of electrons, which it acquires if we move one lone pair from each O atom into its bond with the N atom, as shown below.



(10.14)

Assess

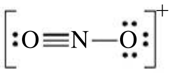
After drawing a Lewis structure, and before moving on to the next step of a problem or to the next exercise, check the structure. Each atom is surrounded by 8 electrons (each atom has an octet), and the structure has a total valence of 16 (we have not inadvertently added or dropped electrons). In assessing the structure, we must remember that each line represents *two* electrons (a bonding pair).

PRACTICE EXAMPLE A: Write plausible Lewis structures for the following ions: **(a)** NO^+; **(b)** $N_2H_5^+$; **(c)** O^{2-}.

PRACTICE EXAMPLE B: Write plausible Lewis structures for the following ions: **(a)** BF_4^-; **(b)** NH_3OH^+; **(c)** NCO^-.

Formal Charge

Instead of writing Lewis structure (10.15) for the nitronium ion in Example 10-6, we might have written the following structure.



(*Improbable*) **(10.15)**

Despite the fact that this structure satisfies the usual requirements—the correct number of valence electrons and an octet for each atom—we have marked it improbable because it fails in one additional requirement. Have you noticed that in our strategy for writing Lewis structures, once the total number of valence electrons has been determined, there is no need to keep track of which electrons came from which atoms? Nevertheless, after we have a plausible Lewis structure, we can go back and assess where each electron apparently came from, and in this way we can evaluate formal charges. **Formal charges (FC)** are apparent charges on certain atoms in a Lewis structure that arise when atoms have not contributed equal numbers of electrons to the covalent bonds joining them. In cases where more than one Lewis structure seems possible, formal charges are used to ascertain which sequence of atoms and arrangement of bonds is most satisfactory.

The formal charge on an atom in a Lewis structure is the number of valence electrons in the free (uncombined) atom minus the number of electrons assigned to that atom in the Lewis structure, with the electrons assigned in the following way.

- Count *lone-pair electrons* as belonging entirely to the atom on which they are found.
- Divide *bond-pair electrons* equally between the bonded atoms.

Assigning electrons (e^-) in this way is equivalent to writing that

$$\begin{aligned}&e^- \text{ assigned to a bonded atom in a Lewis structure}\\&\qquad = \text{number lone-pair } e^- + \frac{1}{2}\text{number bond-pair } e^-\end{aligned}$$

Because formal charge is the difference between the assignment of valence electrons to a free (uncombined) atom and to the atom in a Lewis structure, it can be expressed as

$$\text{FC} = \text{number valence } e^- \text{ in free atom} - \text{number lone-pair } e^- - \frac{1}{2}\text{number bond-pair } e^- \qquad \textbf{(10.16)}$$

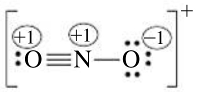
Now, let us assign formal charges to the atoms in structure (10.15), proceeding from left to right.

$$:\!O\equiv \quad \text{FC} = 6 \text{ valence } e^- \text{ in O} - 2 \text{ lone-pair } e^- - \tfrac{1}{2}(6 \text{ bond-pair } e^-) = 6 - 2 - 3 = +1$$

$$\equiv N - \quad \text{FC} = 5 \text{ valence } e^- \text{ in N} - 0 \text{ lone-pair } e^- - \tfrac{1}{2}(8 \text{ bond-pair } e^-) = 5 - 0 - 4 = +1$$

$$-\overset{\cdot\cdot}{\underset{\cdot\cdot}{O}}\!: \quad \text{FC} = 6 \text{ valence } e^- \text{ in O} - 6 \text{ lone-pair } e^- - \tfrac{1}{2}(2 \text{ bond-pair } e^-) = 6 - 6 - 1 = -1$$

Formal charges in a Lewis structure can be shown by using small, encircled numbers.



(10.17)

The following are general rules that can help to determine the plausibility of a Lewis structure based on its formal charges.

- The sum of the formal charges in a Lewis structure must equal *zero* for a neutral molecule and must equal the magnitude of the charge for a polyatomic ion. [Thus for structure (10.17), this sum is $+1 + 1 - 1 = +1$.]
- Where formal charges are required, they should be as small as possible.
- Negative formal charges usually appear on the most electronegative atoms; positive formal charges, on the least electronegative atoms.
- Structures having formal charges of the same sign on adjacent atoms are unlikely.

◀ We will see some exceptions to the idea that formal charges should be kept to a minimum in Section 10-6.

Lewis structure (10.17) conforms to the first two rules, but is not in good accordance with the third rule. Despite the fact that O is the most electronegative element in the structure, one of the O atoms has a positive formal charge. The greatest failing, though, is in the fourth rule. Both the O atom on the left and the N atom adjacent to it have positive formal charges. Structure (10.17) is not the most satisfactory Lewis structure. By contrast, the Lewis structure of NO_2^+ derived in Example 10-7 has only one formal charge, +1, on the central N atom. It conforms to the rules completely and is the most satisfactory Lewis structure.

EXAMPLE 10-8 Using Formal Charges in Writing Lewis Structures

Write the most plausible Lewis structure of nitrosyl chloride, NOCl, one of the oxidizing agents present in *aqua regia*, a mixture of concentrated nitric and hydrochloric acids capable of dissolving gold.

Analyze

Although the formula is written as NOCl, we can reject the skeletal structure N—O—Cl because it places the most electronegative atom as the central atom. (We are asked to consider N—O—Cl in Practice Example A.) Having ruled out N—O—Cl as a possible skeletal structure, we are left with the following as possibilities:

O—Cl—N and O—N—Cl

(continued)

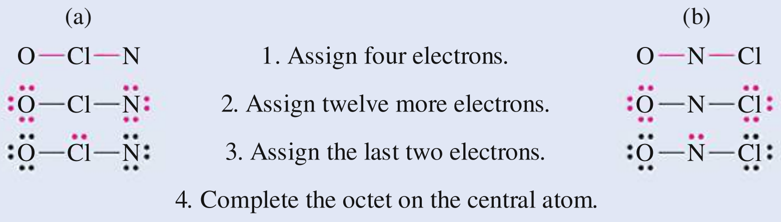
To determine the best structure, we must first complete the skeletal structures and then assign formal charges. The best structure will have the fewest and smallest formal charges.

Solve

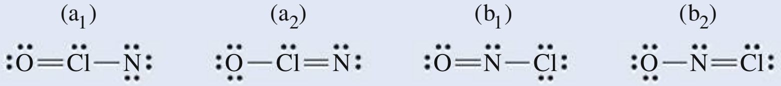
Regardless of the skeletal structure chosen, the number of valence electrons (dots) that must appear in the final Lewis structure is

$$5 \text{ from N} + 6 \text{ from O} + 7 \text{ from Cl} = 18$$

When we apply the four steps listed below to the two possible skeletal structures, we obtain a total of four Lewis structures—two for each skeletal structure. This doubling occurs because in step 4, there are two ways to complete the octets of the central atoms. The final Lewis structures obtained are labeled (a_1), (a_2), (b_1), and (b_2).



1. Assign four electrons.
2. Assign twelve more electrons.
3. Assign the last two electrons.
4. Complete the octet on the central atom.



Evaluate formal charges by using equation (10.16). In structure (a_1),

for the N atom,

$$\text{FC} = 5 - 6 - \frac{1}{2}(2) = -2$$

for the O atom,

$$\text{FC} = 6 - 4 - \frac{1}{2}(4) = 0$$

for the Cl atom,

$$\text{FC} = 7 - 2 - \frac{1}{2}(6) = +2$$

Proceed in a similar manner for the other three structures. Summarize the formal charges for the four structures.

	(a_1)	(a_2)	(b_1)	(b_2)
N:	−2	−1	0	0
O:	0	−1	0	−1
Cl:	+2	+2	0	+1

Select the best Lewis structure in terms of the formal-charge rules. First, note that all four structures obey the requirement that formal charges of a neutral molecule add up to zero. In structure (a_1), the formal charges are large (+2 on Cl and −2 on N) and the negative formal charge is not on the most electronegative atom. Structure (a_2) has formal charges on all atoms, one of them large (+2 on Cl). Structure (b_1) is the ideal we seek—no formal charges. In structure (b_2), we again have formal charges. The best Lewis structure of nitrosyl chloride is

$$:\ddot{O}=\ddot{N}-\underset{\cdot\cdot}{\ddot{Cl}}:$$

Assess

Based on structure (b_1), ONCl is a better way to write the formula of nitrosyl chloride.

PRACTICE EXAMPLE A: Write a Lewis structure for nitrosyl chloride based on the skeletal structure N—O—Cl, and show that this structure is not as plausible as the one obtained in Example 10-8.

PRACTICE EXAMPLE B: Write two Lewis structures for cyanamide, NH_2CN, an important chemical of the fertilizer and plastics industries. Use the formal charge concept to choose the more plausible structure.

10-5 CONCEPT ASSESSMENT

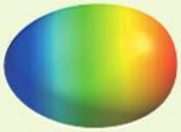
For molecules, the most satisfactory Lewis structure may have no formal charges (FC = 0) in some cases and formal charges in others. For polyatomic ions, minimally the most satisfactory Lewis structure has a formal charge on at least one atom. Explain the basis of these observations.

10-1 ARE YOU WONDERING...

Do formal charges represent actual charges on the atoms?

Formal charges are not actual charges, which can be seen from a comparison of the electrostatic potential map of the HCN molecule and the formal charges derived from the Lewis structure.

$$\underset{\textcircled{0}}{\mathrm{H}}-\underset{\textcircled{0}}{\mathrm{C}}\equiv\underset{\textcircled{0}}{\mathrm{N}}\mathpunct{:}$$



Although the formal charges are all zero, the electrostatic potential map shows that the H atom in the HCN molecule is slightly positive (blue) and that the nitrogen atom is slightly negative (red). In molecules, the true charges on atoms are usually, but not always, between +1 and −1. For example, in the HCl molecule, the charge on H is about +0.17 and that on Cl is about −0.17. (See page 431.)

The method used for assigning formal charges is really just a form of "electron bookkeeping." In this text, we have now discussed two different concepts—oxidation states and formal charges—that are used for electron bookkeeping. Oxidation states and formal charges are both very useful. They are compared in the table below.

	Interpretation	Comments
Oxidation state	The charge an atom would have if the bonding electrons in each bond were *transferred* to the more electronegative atom.	• The oxidation state concept tends to exaggerate the ionic character of the bonding between atoms. • Oxidation states are used to predict and rationalize chemical properties of compounds.
Formal charge	The charge an atom would have if the bonding electrons in each bond were *divided equally* between the two atoms involved.	• The formal charge concept tends to exaggerate the covalent character of the bonding between atoms. • Formal charges are used to assess which Lewis structure is the most satisfactory representation of the true structure.

For many molecules, the bonding is closer to being "pure covalent" than it is to being "pure ionic" and so the formal charge on an atom is often—but not always—numerically closer to the true charge. That's why we focus on formal charges when assessing the relative importance of different Lewis structures. That being said, it is important to emphasize that chemists still question and debate whether it is true that the best structure is the one having the fewest and smallest formal charges.

10-5 Resonance

The ideas presented in the previous section allow us to write many Lewis structures, but some structures still present problems. We describe these problems in the next two sections.

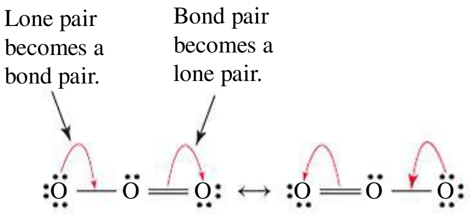
Although we usually think of the formula of oxygen as O_2, there are actually two different oxygen molecules. Familiar oxygen is *dioxygen*, O_2; the other molecule is *trioxygen*—ozone, O_3. The term used to describe the existence of two or more forms of an element that differ in their bonding and molecular structure is *allotropy*—O_2 and O_3 are allotropes of oxygen. Ozone is found naturally in the stratosphere and is also produced in the lower atmosphere as a constituent of smog.

When we apply the usual rules for Lewis structures for ozone, we come up with these *two* possibilities.

▶ Bond lengths are discussed more fully in Section 10-8.

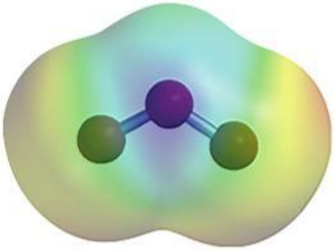
$$:\ddot{O}=\ddot{O}-\underset{..}{\ddot{O}}: \qquad :\underset{..}{\ddot{O}}-\ddot{O}=\ddot{O}:$$

Each structure suggests that one oxygen-to-oxygen bond is single and the other is double. Yet experimental evidence indicates that the two oxygen-to-oxygen bonds are the same; each has a length of 127.8 pm. This bond length is shorter than the O—O single-bond length of 147.5 pm in hydrogen peroxide, $H-\underset{..}{\ddot{O}}-\underset{..}{\ddot{O}}-H$, but it is longer than the double-bond length of 120.74 pm in diatomic oxygen, $:\ddot{O}=\ddot{O}:$. The bonds in ozone are intermediate between a single and a double bond. The difficulty is resolved if we say that the true Lewis structure of O_3 is *neither* of the previously proposed structures but a composite, or *hybrid*, of the two, a fact that we can represent as

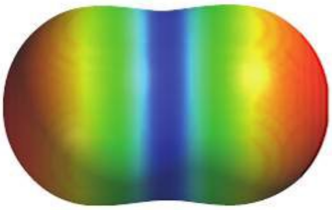


Lone pair becomes a bond pair.
Bond pair becomes a lone pair.

(10.18)



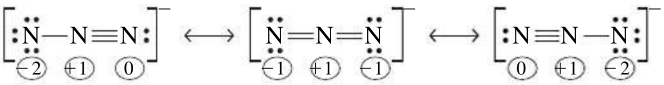
▲ **Electrostatic potential map of ozone**
All the atoms in an ozone molecule have the same electronegativity and yet the distribution of electron density is nonuniform. The reason will become apparent when we describe in a more sophisticated way the bonding in this molecule.



▲ **Electrostatic potential map of the azide anion**

The situation in which two or more plausible Lewis structures contribute to the "correct" structure is called **resonance**. The true structure is a *resonance hybrid* of plausible contributing structures. Acceptable contributing structures to a resonance hybrid must all have the same skeletal structure (the atomic positions cannot change); they can differ only in how electrons are distributed within the structure. In expression (10.18), the two contributing structures are joined by a double-headed arrow. The arrow does *not* mean that the molecule has one structure part of the time and the other structure the rest of the time. *It has the same structure all the time.* By averaging the single bond in one structure with the double bond in the other, we might say that the oxygen-to-oxygen bonds in ozone are halfway between a single and double bond, that is, 1.5 bonds. The fact that the electrons in ozone are distributed over the whole molecule so as to produce two equivalent bonds is readily seen in the electrostatic potential map of ozone, shown in the margin.

The two resonance structures in expression (10.18) are equivalent; that is, they contribute equally to the structure of the resonance hybrid. In many cases, several contributing resonance structures do not contribute equally. For example, consider the azide anion, N_3^-, for which three resonance structures are given below.



We can decide which resonance structure likely contributes most to the hybrid by applying the general rules for formal charges (page 413). The central resonance structure avoids the unlikely large formal charge of −2 found on an N atom in the other two structures. Consequently, we expect that structure to contribute most to the resonance hybrid of the azide anion.

EXAMPLE 10-9 Representing the Lewis Structure of a Resonance Hybrid

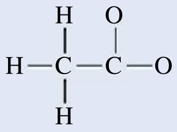
Write the Lewis structure of the acetate ion, CH_3COO^-.

Analyze

A key concept is that resonance structures differ only in how electrons are distributed within the structure. We cannot change the positions of the atoms. First, we draw a skeletal structure (see the electrostatic potential map shown in the margin), and then we complete it by using the strategy we've used previously. Finally, we generate additional structures (resonance structures) by moving electron pairs.

Solve

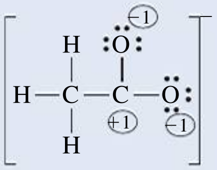
The skeletal structure has the three H atoms as terminal atoms bonded to a C atom as a central atom. The second C atom is also a central atom bonded to the first. The two O atoms are terminal atoms bonded to the second C atom.



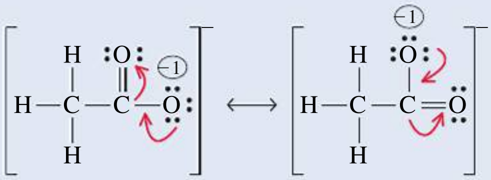
The number of valence electrons (dots) that must appear in the Lewis structure is

$$\underset{\text{From H}}{(3 \times 1)} + \underset{\text{From C}}{(2 \times 4)} + \underset{\text{From O}}{(2 \times 6)} + \underset{\substack{\uparrow \\ \text{To establish charge of } 1-}}{1} = 3 + 8 + 12 + 1 = 24$$

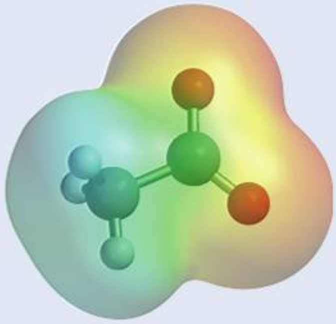
Twelve of the valence electrons are used in the bonds in the skeletal structure, and the remaining twelve are distributed as lone-pair electrons on the two O atoms.



In completing the octet of the C atom on the right, we discover that we can write two completely equivalent Lewis structures, depending on which of the two O atoms furnishes the lone pair of electrons to form a carbon-to-oxygen double bond. The true Lewis structure is a resonance hybrid of the following two contributing structures.



(10.19)



▲ Acetate anion

Assess

Even though the formal process of converting one resonance structure to another moves electrons, resonance is not meant to indicate the motion of electrons. The acetate anion has a structure that is a composite of the two resonance forms that we have constructed.

PRACTICE EXAMPLE A: Draw Lewis structures to represent the resonance hybrid for the SO_2 molecule.

PRACTICE EXAMPLE B: Draw Lewis structures to represent the resonance hybrid for the nitrate ion.

10-6 CONCEPT ASSESSMENT

Is resonance possible in the acetic acid (CH_3CO_2H) molecule? Explain.

10-6 Exceptions to the Octet Rule

The octet rule has been our mainstay in writing Lewis structures, and it will continue to be one. Yet at times, we must depart from the octet rule, as we will see in this section.

Odd-Electron Species

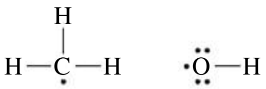
The molecule NO has 11 valence electrons, an odd number. If the number of valence electrons in a Lewis structure is odd, there must be an unpaired electron somewhere in the structure. Lewis theory deals with electron pairs and does not tell us where to put the unpaired electron; it could be on either the N or the O atom. To obtain a structure free of formal charges, however, we will put the unpaired electron on the N atom.

$$\cdot\ddot{N}=\ddot{O}:$$

The presence of unpaired electrons causes odd-electron species to be paramagnetic. NO is paramagnetic. Molecules with an even number of electrons are expected to have all electrons paired and to be diamagnetic. An important exception is seen in the case of O_2, which is paramagnetic despite having 12 valence electrons. Lewis theory does not provide a good electronic structure for O_2, but the molecular orbital theory that we will consider in the next chapter is much more successful.

▶ Experimental evidence for the paramagnetism of O_2 is shown in Figure 10-3.

The number of stable odd-electron molecules is quite limited. More common are **free radicals**, or simply *radicals*, highly reactive molecular fragments with one or more unpaired electrons. The formulas of free radicals are usually written with a dot to emphasize the presence of an unpaired electron, such as in the *methyl* radical, $\cdot CH_3$, and the *hydroxyl* radical, $\cdot OH$. The Lewis structures of these two free radicals are



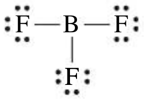
Both of these free radicals are commonly encountered as transitory species in flames. In addition, $\cdot OH$ is formed in the atmosphere in trace amounts as a result of photochemical reactions.

$$\cdot OH + CO \longrightarrow CO_2 + \cdot H$$

Many important atmospheric reactions involve free radicals as reactants, such as in the above oxidation of CO to CO_2. Free radicals, because of their unpaired electron, are highly reactive species. The hydroxyl radical, for example, is implicated in DNA damage that can lead to cancer.

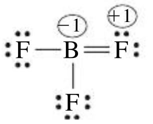
Incomplete Octets

Our initial attempt to write the Lewis structure of boron trifluoride leads to a structure in which the B atom has only *six* electrons in its valence shell—an *incomplete octet*.



(10.20)

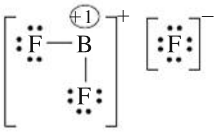
We have learned to complete the octets of central atoms by shifting lone-pair electrons from terminal atoms to form multiple bonds. One of three equivalent structures with a boron-to-fluorine double bond is shown below.



(10.21)

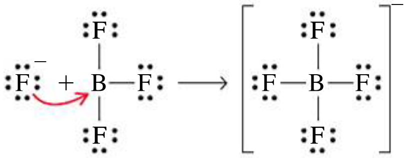
An observation in support of structure (10.21) is that the B—F bond length in BF_3 (130 pm) is less than expected for a single bond. A shorter bond suggests that more than two electrons are present, that is, that there is multiple-bond character in the bond. However, the placement of formal charges in structure (10.18) breaks an important rule—negative formal charge should be found on the more electronegative atom in the bond. In this structure, the positive formal charge is on the most electronegative of all atoms—F.

The high electronegativity of fluorine (4.0) and the much lower one of boron (2.0) suggest an appreciable ionic character to the boron-to-fluorine bond (see Figure 10-7). This suggests the possibility of such ionic structures as the following.



(10.22)

In view of its molecular properties and chemical behavior, the best representation of BF_3 appears to be a resonance hybrid of structures (10.20, 10.21, and 10.22), with perhaps the most important contribution made by the structure with an incomplete octet (10.20). Whichever BF_3 structure we choose to emphasize, an important characteristic of BF_3 is its strong tendency to form a coordinate covalent bond with a species capable of donating an electron pair to the B atom. This can be seen in the formation of the BF_4^- ion.



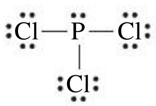
In BF_4^-, the bonds are single bonds and the bond length is 145 pm.

The number of species with incomplete octets is limited to some beryllium, boron, and aluminum compounds. Perhaps the best examples are the boron hydrides. Bonding in the boron hydrides will be discussed in Chapter 22.

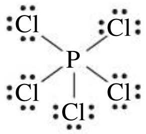
Expanded Valence Shells

We have consistently tried to write Lewis structures in which all atoms except H have a complete octet, that is, in which each atom has eight valence electrons. There are a few Lewis structures that break this rule by having 10 or even 12 valence electrons around the central atom, creating what is called an **expanded valence shell**. Describing bonding in these structures is an area of active interest among chemists.

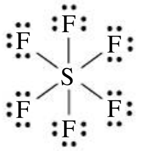
Molecules with expanded valence shells typically involve nonmetal atoms of the third period and beyond that are bonded to highly electronegative atoms. For example, phosphorus forms two chlorides, PCl_3 and PCl_5. We can write a Lewis structure for PCl_3 with the octet rule. In PCl_5, with five Cl atoms bonded directly to the central P atom, the outer shell of the P atom appears to have *ten* electrons. We might say that the valence shell has expanded to ten electrons. In the SF_6 molecule, the valence shell appears to expand to 12.



Octet

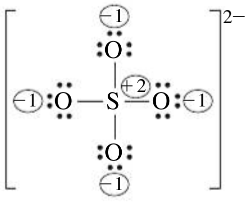


Expanded valence shell

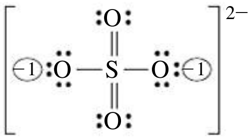


Expanded valence shell

Expanded valence shells have also been used in cases where they appear to give a better Lewis structure than strict adherence to the octet rule, as suggested by the two Lewis structures for the sulfate ion that follow.

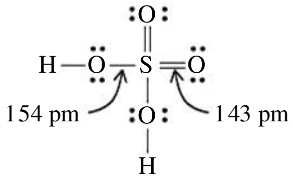


Normal octet



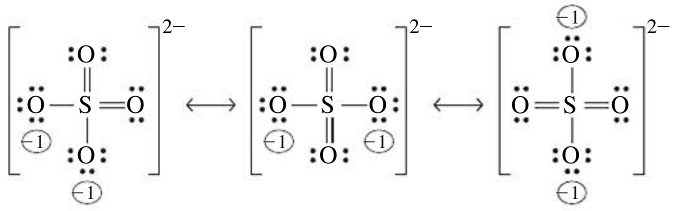
Expanded valence shell

The argument for including the expanded valence-shell structure is that it reduces formal charges. Also, the experimentally determined sulfur-to-oxygen bond lengths in SO_4^{2-} and H_2SO_4 are in agreement with this idea. The experimental results for H_2SO_4, summarized in structure (10.23), indicate that the S—O bond with O as a central atom and with an attached H atom is longer than the S—O bond with O as a terminal atom.



(10.23)

Experimental evidence appears to support using an expanded valence shell in the Lewis structure of sulfuric acid. The experimentally determined S—O bond length in the sulfate anion—149 pm—lies between the two S—O bond lengths found in sulfuric acid, suggesting a partial double-bond character. The expanded valence-shell structure is suggestive of this partial double-bond character, whereas the octet structure is not. For the sulfate anion, best agreement with the observed S—O bond lengths is found in a resonance hybrid having strong contributions from a series of resonance structures (10.24) based on expanded valence shells.



(10.24)

The problem with expanded valence-shell structures is, of course, to explain where the "extra" electrons go. This expansion has been rationalized by assuming that after the 3*s* and 3*p* subshells of the central atom fill to capacity (eight electrons), extra electrons go into the empty 3*d* subshell. If we assume that the energy difference between the 3*p* and 3*d* levels is not very large, the valence-shell expansion scheme seems reasonable. But is this a valid assumption? The use of the 3*d* orbitals for valence-shell expansion is a matter of scientific dispute.* Although unresolved questions about the expanded

---

*L. Suidan et al., *J. Chem. Educ.*, **72**, 583 (1995); G. H. Purser, *J. Chem. Educ.*, **78**, 981 (2001).

valence-shell concept may be unsettling, the point to keep in mind is that the unmodified octet rule works perfectly well for most uses of Lewis structures. We will return to this topic, together with several other unsettled issues, in the concluding section of Chapter 11.

10-7 CONCEPT ASSESSMENT

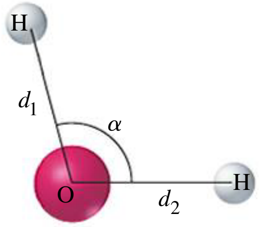
On page 416, we reasoned that because of resonance, oxygen–oxygen bonds in O_3 were halfway between single and double bonds, that is, 1.5 bonds. Do you expect the sulfur–oxygen bonds in SO_2 to be single, double, or 1.5 bonds? Explain your answer, bearing in mind the ability of sulfur to expand its valence shell.

10-7 Shapes of Molecules

The Lewis structure for water gives the impression that the constituent atoms are arranged in a straight line.

$$\mathrm{H{-}\ddot{\underset{\cdot\cdot}{O}}{-}H}$$

However, the experimentally determined shape of the molecule is not linear. The molecule is *bent*, as shown in Figure 10-9. Does it really matter that the H_2O molecule is bent rather than linear? The answer is, decidedly, yes. As we will learn in Chapter 12, the bent shape of water molecules helps to account for the fact that water is a liquid rather than a gas at room temperature. In Chapter 13, we will find that it also accounts for the ability of liquid water to dissolve so many different substances.



▲ FIGURE 10-9
Geometric shape of a molecule
To establish the shape of the triatomic H_2O molecule shown here, we need to determine the distances between the nuclei of the bonded atoms and the angle between adjacent bonds. In H_2O, the bond lengths $d_1 = d_2 = 95.8$ pm and the bond angle $\alpha = 104.45°$.

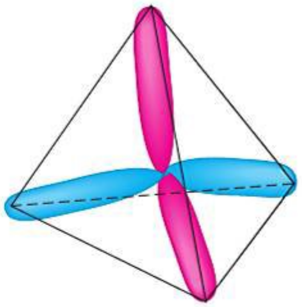
What we seek in this section is a simple model for predicting the approximate shape of a molecule. Unfortunately, Lewis theory tells us nothing about the shapes of molecules, but it is an excellent place to begin. The next step is to use an idea based on repulsions between valence-shell electron pairs. We will discuss this idea after defining a few terms.

By molecular shape, we mean the geometric figure we get when joining the nuclei of bonded atoms by straight lines. Figure 10-9 depicts the *triatomic* (three-atom) water molecule using a ball-and-stick model. The balls represent the three atoms in the molecule, and the straight lines (sticks), the bonds between atoms. In reality, the atoms in the molecule are in close contact, but for clarity we show only the centers of the atoms. To have a complete description of the shape of a molecule, we need to know not only the bond lengths, the distances between the nuclei of bonded atoms, but also the **bond angles**, the angles between adjacent lines representing bonds. We will concentrate on bond angles in this section and bond lengths in Section 10-8.

A diatomic molecule has only one bond and no bond angle. Because the geometric shape determined by two points is a straight line, *all diatomic molecules are linear*. A triatomic molecule has two bonds and one bond angle. If the bond angle is 180°, the three atoms lie on a straight line, and the molecule is *linear*. For any other bond angle, a triatomic molecule is said to be *angular, bent*, or *V-shaped*. Some polyatomic molecules with more than three atoms have planar or even linear shapes. More commonly, however, the centers of the atoms in these molecules define a three-dimensional geometric figure.

Valence-Shell Electron-Pair Repulsion (VSEPR) Theory

The shape of a molecule is established by experiment or by a quantum mechanical calculation confirmed by experiment. The results of these experiments and calculations are generally in good agreement with the **valence-shell electron-pair repulsion theory (VSEPR)**. In VSEPR theory, we focus on *pairs* of electrons in the *valence* electron shell of a central atom in a structure.



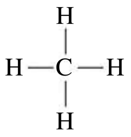
▲ FIGURE 10-10
Balloon analogy to valence-shell electron-pair repulsion
When two elongated balloons are twisted together, they separate into four lobes. To minimize interferences, the lobes spread out into a tetrahedral pattern. (A regular tetrahedron has four faces, each an equilateral triangle.) The lobes are analogous to valence-shell electron pairs.

> Electron pairs repel each other, whether they are in chemical bonds (bond pairs) or unshared (lone pairs). Electron pairs assume orientations about an atom to minimize repulsions.

This, in turn, results in particular geometric shapes for molecules.

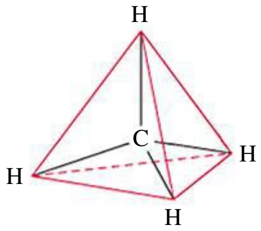
Another aspect of VSEPR theory is a focus not just on electron pairs but on electron *groups*. A group of electrons can be a pair, either a lone pair or a bond pair, or it can be a single unpaired electron on an atom with an incomplete octet, as in NO. A group can also be a double or triple bond between two atoms. Thus in the $\underset{\cdot\cdot}{\ddot{O}}=C=\underset{\cdot\cdot}{\ddot{O}}$ molecule, the central C atom has *two* electron groups in its valence shell. Each of the double bonds with its two electron pairs is treated as *one* electron group.

Consider the methane molecule, CH_4, in which the central C atom has acquired the electron configuration of Ne by forming covalent bonds with four H atoms.



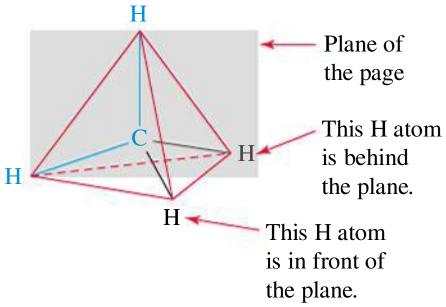
$$\begin{array}{ccccc} & & H & & \\ & & | & & \\ H & — & C & — & H \\ & & | & & \\ & & H & & \end{array}$$

What orientation will the four electron groups (bond pairs) assume? The balloon analogy of Figure 10-10 suggests that electron-group repulsions will force the groups as far apart as possible—to the corners of a tetrahedron having the C atom at its center. The VSEPR method predicts, correctly, that CH_4 is a *tetrahedral* molecule.



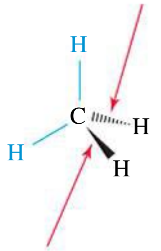
Having established that the molecular shape of methane is tetrahedral, the following question arises: How can we represent the three-dimensional shape of molecule on a sheet of paper? In the diagram in the margin, we have enclosed a methane molecule in a tetrahedron (red lines).

We see that the C—H bonds point to the vertices of the tetrahedron. Any two of the C—H bonds define a plane, and in the figures below we choose two C—H bonds (shown in blue) to lie in the plane of the page.



H
Plane of the page
C
H
H
This H atom is behind the plane.
H
This H atom is in front of the plane.

The dashed wedge represents a bond that points behind the plane of the page.



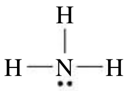
The solid wedge represents a bond that points out of the plane of the page.

When examining the figure above, we can see that the other two C—H bonds do not lie in the plane of the page. One of the C—H bonds points out of the plane of the page (toward us) and the other points behind (away from us). In the figure in the lower margin, we use a solid wedge to represent the bond that points toward us and a dashed wedge to represent the bond that points away.

The *dash and wedge* symbolism described above is routinely used by chemists to represent three-dimensional structures of molecules. The symbolism is based on the following conventions:

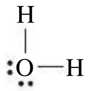
- Ordinary lines are used to represent bonds that lie in the plane of the paper.
- Solid wedges are used to represent bonds that point toward the viewer, that is, in front of the plane of the paper.
- Dashed wedges are used to represent bonds that point away from the viewer, that is, behind the plane of the paper.

In NH_3 and H_2O, the central atom is also surrounded by four groups of electrons, but these molecules *do not* have a tetrahedral shape.



$$H-\underset{\cdot\cdot}{\overset{\overset{\displaystyle H}{|}}{N}}-H$$

and

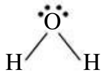


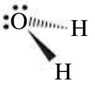
$$:\underset{\cdot\cdot}{\overset{\overset{\displaystyle H}{|}}{O}}-H$$

Here is the situation: VSEPR theory predicts the distribution of electron groups, and in these molecules, electron groups are arranged tetrahedrally about the central atom. The shape of a molecule, however, is determined by the location of the atomic nuclei. To avoid confusion, we will call the geometric distribution of electron groups the **electron-group geometry** and the geometric arrangement of the atomic nuclei—the actual determinant of the molecular shape—the **molecular geometry**.

In the NH_3 molecule, only three of the electron groups are bond pairs; the fourth is a lone pair. Joining the N nucleus to the H nuclei by straight lines outlines a pyramid with the N atom at the apex and the three H atoms at the base; it is called a *trigonal pyramid*. We say that the electron-group geometry is tetrahedral and the molecular geometry is trigonal-pyramidal.

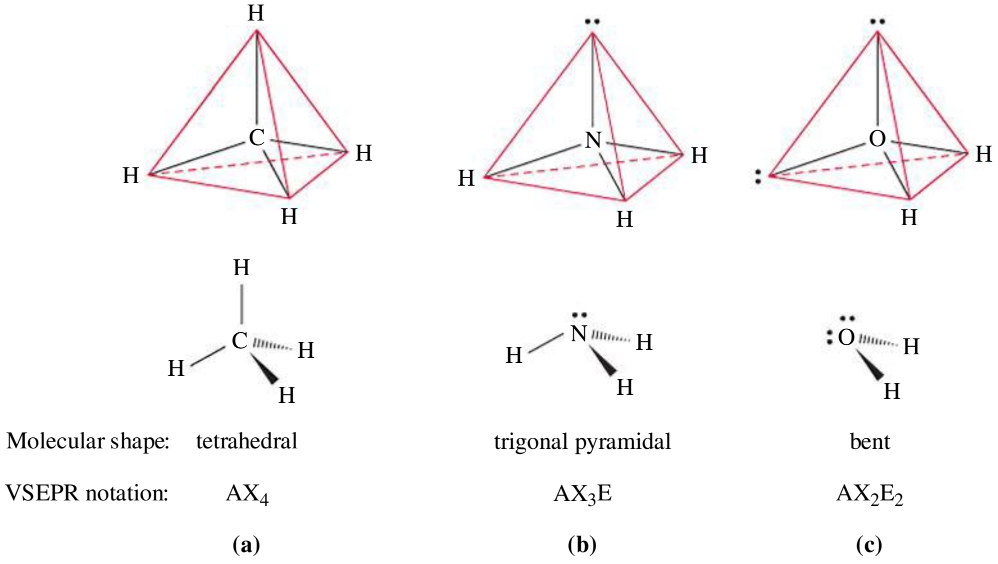
In the H_2O molecule, two of the four electron groups are bond pairs and two are lone pairs. The molecular shape is obtained by joining the two H nuclei to the O nucleus with straight lines. For H_2O, the electron-group geometry is tetrahedral and the molecular geometry is V-shaped, or bent. In the diagram below, the Lewis structure for water is drawn in two ways.





In the first diagram, which is how we usually draw the structure, all the atoms lie on the plane of the paper. In the second structure, we use dash and wedge symbols to indicate that one of the bonds points toward us and the other points away.

The geometric shapes of CH_4, NH_3, and H_2O are summarized in Figure 10-11. In the VSEPR notation used in Figure 10-11, A is the central atom, X



▲ FIGURE 10-11
Molecular shapes based on tetrahedral electron-group geometry of CH_4, NH_3, and H_2O
All three molecules have a tetrahedral arrangement of electron groups around the central atom. However, molecular shapes (or molecular geometries) are established by focusing only on the positions of the atoms. Pretend that lone pairs are invisible when visualizing the molecular shapes. In (a), there are no lone pairs and the C atom sits at the center of a tetrahedron; the molecular shape is tetrahedral. Pretending the lone pair on the N atom in (b) is invisible, the N atom is the vertex in a pyramid having a triangular base; the molecular shape is called trigonal pyramidal. In (c), the O and H atoms form a V-shape and the molecular shape is V-shaped or bent.

is a terminal atom or group of atoms bonded to the central atom, and E is a lone pair of electrons. Thus, the symbol AX_2E_2 signifies that *two* atoms or groups (X) are bonded to the central atom (A). The central atom also has *two* lone pairs of electrons (E). H_2O is an example of a molecule of the AX_2E_2 type.

For tetrahedral electron-group geometry, we expect bond angles of 109.5°, known as the *tetrahedral* bond angle. In the CH_4 molecule, the measured bond angles are, in fact, 109.5°. The bond angles in NH_3 and H_2O are slightly smaller: 107° for the H—N—H bond angle and 104.5° for the H—O—H bond angle. We can explain these less-than-tetrahedral bond angles by the fact that the charge cloud of the lone-pair electrons spreads out. This forces the bond-pair electrons closer together and reduces the bond angles.

VSEPR theory works best for second-period elements. The predicted bond angle of 109.5° for H_2O is close to the measured angle of 104.5°. For H_2S, however, the predicted value of 109.5° is not in good agreement with the observed value, 92°. Even though VSEPR theory does not give an accurate prediction for the angle in H_2S, it does provide an indication that the molecule is bent.

Possibilities for Electron-Group Distributions

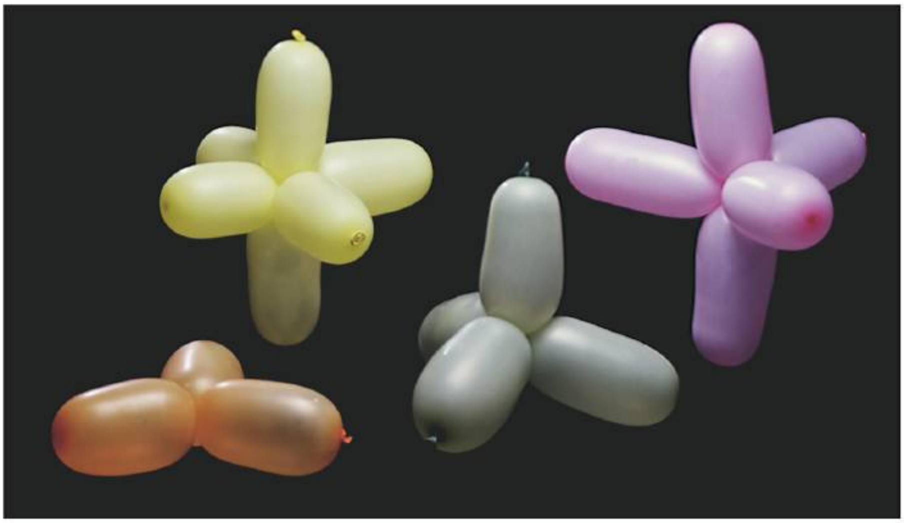
The most common situations are those in which central atoms have two, three, four, five, or six electron groups distributed around them.

Electron-group geometries

- two electron groups: linear
- three electron groups: trigonal planar
- four electron groups: tetrahedral
- five electron groups: trigonal bipyramidal
- six electron groups: octahedral

Figure 10-12 extends the balloon analogy to these cases. The cases for five- and six-electron groups are typified by PCl_5 and SF_6, molecules with expanded valence shells.

The molecular geometry is the same as the electron-group geometry *only* when all electron groups are bond pairs. These are for the VSEPR notation AX_n (that is, AX_2, AX_3, AX_4, and so on). In Table 10.1, the AX_n cases are illustrated by



▶ FIGURE 10-12
Several electron-group geometries illustrated
The electron-group geometries pictured are trigonal-planar (orange), tetrahedral (gray), trigonal-bipyramidal (pink), and octahedral (yellow). The atoms at the ends of the balloons are not shown and are not important in this model.

TABLE 10.1 Molecular Geometry as a Function of Electron-Group Geometry

Number of Electron Groups	Electron-Group Geometry	Number of Lone Pairs	VSEPR Notation	Molecular Geometry	Ideal Bond Angles	Example	
2	linear	0	AX_2	 (linear)	180°	$BeCl_2$	
3	trigonal planar	0	AX_3	 (trigonal planar)	120°	BF_3	
	trigonal planar	1	AX_2E	 (bent)	120°	SO_2^a	
4	tetrahedral	0	AX_4	 (tetrahedral)	109.5°	CH_4	
	tetrahedral	1	AX_3E	 (trigonal pyramidal)	109.5°	NH_3	
	tetrahedral	2	AX_2E_2	 (bent)	109.5°	OH_2	
5	trigonal bipyramidal	0	AX_5	 (trigonal bipyramidal)	90°, 120°	PCl_5	

(continued)

TABLE 10.1 Molecular Geometry as a Function of Electron-Group Geometry (Continued)

Number of Electron Groups	Electron-Group Geometry	Number of Lone Pairs	VSEPR Notation	Molecular Geometry	Ideal Bond Angles	Example

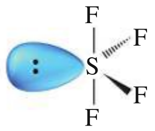
[b] For a discussion of the placement of the lone-pair electrons in this structure, see page 427.

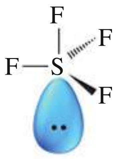
photographs of ball-and-stick models. If one or more electron groups are lone pairs, the molecular geometry is different from the electron-group geometry, although still derived from it. The relationship between electron-group geometry and molecular geometry is summarized in Table 10.1. To understand all the cases in Table 10.1, we need two more ideas.

- *The closer together two groups of electrons are forced, the stronger the repulsion between them.* The repulsion between two electron groups is much stronger at an angle of 90° than at 120° or 180°.
- *Lone-pair electrons spread out more than do bond-pair electrons.* As a result, the repulsion of one lone pair of electrons for another lone pair is greater than, say, between two bond pairs. The order of repulsive forces, from strongest to weakest, is

$$\text{lone pair–lone pair} > \text{lone pair–bond pair} > \text{bond pair–bond pair}$$

Consider SF_4, with the VSEPR notation AX_4E. Two possibilities for its structure are presented in the margin, but only one is correct. The correct structure (top)





EXAMPLE 10-10 Using VSEPR Theory to Predict a Geometric Shape

Predict the molecular geometry of the polyatomic anion ICl_4^-.

Analyze

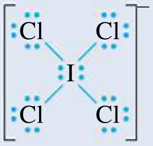
To solve this problem, apply the four steps outlined on page 428.

Solve

Step 1. Write the Lewis structure. The number of valence electrons is

From I	From Cl	To establish ionic charge of -1	
(1×7)	$(4 \times 7) +$	1	$= 36$

To join 4 Cl atoms to the central I atom and to provide octets for all the atoms, we need 32 electrons. In order to account for all 36 valence electrons, we need to place an *additional* four electrons around the I atom as lone pairs. That is, we are forced to expand the valence shell of the I atom to accommodate all the electrons required in the Lewis structure.



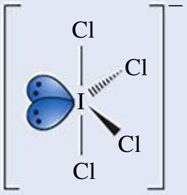
Step 2. There are six electron groups around the I atom, four *bond pairs* and two *lone pairs*.

Step 3. The electron-group geometry (the orientation of six electron groups) is *octahedral*.

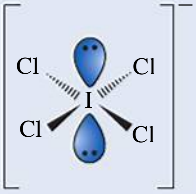
Step 4. The ICl_4^- anion is of the type AX_4E_2, which according to Table 10.1, leads to a molecular geometry that is square planar.

Assess

Figure 10-13 suggests two possibilities for distributing bond pairs and lone pairs in ICl_4^-. The square planar structure is correct because the lone pair–lone pair interaction is kept at 180°. In the incorrect structure, this interaction is at 90°, which results in a strong repulsion.



(Incorrect)



(Correct)

▲ FIGURE 10-13
Example 10-10 illustrated
The observed structure of ICl_4^- is square planar. The iodine atom has a formal charge of −1 (not shown in the structures above).

PRACTICE EXAMPLE A: Predict the molecular geometry of nitrogen trichloride.

PRACTICE EXAMPLE B: Predict the molecular geometry of phosphoryl chloride, $POCl_3$, an important chemical in the manufacture of gasoline additives, hydraulic fluids, and fire retardants.

places a lone pair of electrons in the central plane of the bipyramid. As a result, *two* lone pair–bond pair interactions are 90°. In the incorrect structure (bottom), the lone pair of electrons is at the bottom of the bipyramid and results in *three* lone pair–bond pair interactions of 90°. This is a less favorable arrangement.

KEEP IN MIND

that we need to expand a valence shell only if more than eight electrons must be accommodated by the central atom in a Lewis structure. This leads to structures based on five or six electron groups. Otherwise, octet-based Lewis structures are perfectly satisfactory when applying the VSEPR theory.

Applying VSEPR Theory

The following four-step strategy can be used for predicting the shapes of molecules.

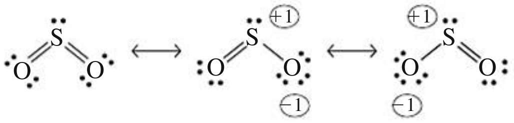
1. Draw a plausible Lewis structure of the species (molecule or polyatomic ion).
2. Determine the number of electron groups around the central atom, and identify them as being either *bond-pair* electron groups or *lone pairs* of electrons.
3. Establish the electron-group geometry around the central atom—linear, trigonal planar, tetrahedral, trigonal bipyramidal, or octahedral.
4. Determine the molecular geometry from the positions of the atoms bonded directly to the central atom. (Refer to Table 10.1.)

10-8 CONCEPT ASSESSMENT

The ions ICl_2^- and ICl_2^+ differ by only two electrons. Would you expect them to have the same geometric shape? Explain.

Structures with Multiple Covalent Bonds

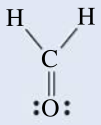
In a multiple covalent bond, all electrons in the bond are confined to the region between the bonded atoms, and together constitute one group of electrons. Let us test this idea by predicting the molecular geometry of sulfur dioxide. S is the central atom, and the total number of valence electrons is 3 × 6 = 18. The Lewis structure is the resonance hybrid of the three contributing structures shown below.



Because we count the electrons in the double covalent bond as one group, the electron-group geometry around the central S atom is that of *three* electron groups—*trigonal-planar*. Of the three electron groups, two are bonding groups and one is a lone pair. This is the case of AX_2E (see Table 10.1). The molecular shape is *angular*, or *bent*, with an expected bond angle of 120°. (The measured bond angle in SO_2 is 119°.)

EXAMPLE 10-11 Using VSEPR Theory to Predict the Shape of a Molecule with a Multiple Covalent Bond

Predict the molecular geometry of formaldehyde, H_2CO, used to make a number of polymers, such as melamine resins. The Lewis structure of the H_2CO molecule is shown here.



Analyze

We see from the Lewis structure that the carbon–oxygen bond is a double bond. When considering molecules with double or triple bonds, we treat a double or triple bond as a single electron group.

Solve

There are three electron groups around the C atom, two groups in the carbon-to-hydrogen single bonds and the third group in the carbon-to-oxygen double bond. The electron-group geometry for three electron groups is *trigonal-planar*. Because all the electron groups are involved in bonding, the VSEPR notation for this molecule is AX_3. The molecular geometry is also trigonal-planar.

Assess

Because the geometry is trigonal planar, we expect the angle between the two H—C bonds to be close to 120°.

PRACTICE EXAMPLE A: Predict the shape of the COS molecule.

PRACTICE EXAMPLE B: Nitrous oxide, N_2O, is the familiar laughing gas used as an anesthetic in dentistry. Predict the shape of the N_2O molecule.

Molecules with More Than One Central Atom

Although many of the structures of interest to us have only one central atom, VSEPR theory can also be applied to molecules or polyatomic anions with more than one central atom. In such cases, the geometric distribution of terminal atoms around *each* central atom must be determined and the results then combined into a single description of the molecular shape. We use this idea in Example 10-12.

EXAMPLE 10-12 Applying VSEPR Theory to a Molecule with More Than One Central Atom

Methyl isocyanate, CH_3NCO, is used in the manufacture of insecticides, such as carbaryl (Sevin). In the CH_3NCO molecule, the three H atoms and the O atom are terminal atoms and the two C and one N atom are central atoms. Draw the structure of this molecule, using dash and wedge symbols, and indicate the various bond angles.

Analyze

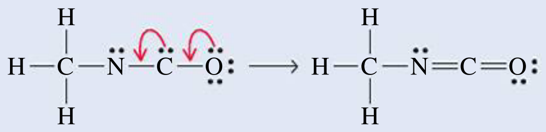
We must first draw a plausible Lewis structure. Then, we determine the electron group geometry around each atom and estimate the angles between pairs of bonds.

Solve

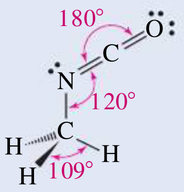
The number of valence electrons in the structure is

From C	From N	From O	From H	
(2 × 4)	(1 × 5)	(1 × 6)	(3 × 1)	= 22

In drawing the skeletal structure and assigning valence electrons, we first obtain a structure with incomplete octets. By shifting the indicated electrons, we can give each atom an octet.



The C atom on the left has four electron groups around it—all bond pairs. The shape of this end of the molecule is *tetrahedral*. The C atom to the right, by forming two double bonds, is treated as having two groups of electrons around it. This distribution is *linear*. For the N atom, three groups of electrons are distributed in a *trigonal planar* manner. The C—N—C bond angle should be about 120°.



Assess

The strategy outlined above can be applied to molecules of varying complexity.

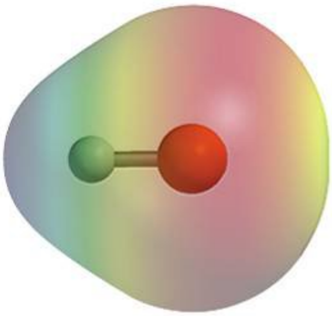
(continued)

PRACTICE EXAMPLE A: Sketch, by using dash and wedge symbols, the methanol molecule, CH_3OH. Indicate the bond angles in this molecule.

PRACTICE EXAMPLE B: Glycine, an amino acid, has the formula H_2NCH_2COOH. Sketch, by using dash and wedge symbols, the glycine molecule, and indicate the various bond angles.

10-9 CONCEPT ASSESSMENT

Methyl isocyanate, CH_3NCO, can be represented as a hybrid of three Lewis structures. The most satisfactory structure is the one given above in Example 10-12. Draw the other two structures. On the basis of formal charges, which of the structures is least satisfactory?



Molecular Shapes and Dipole Moments

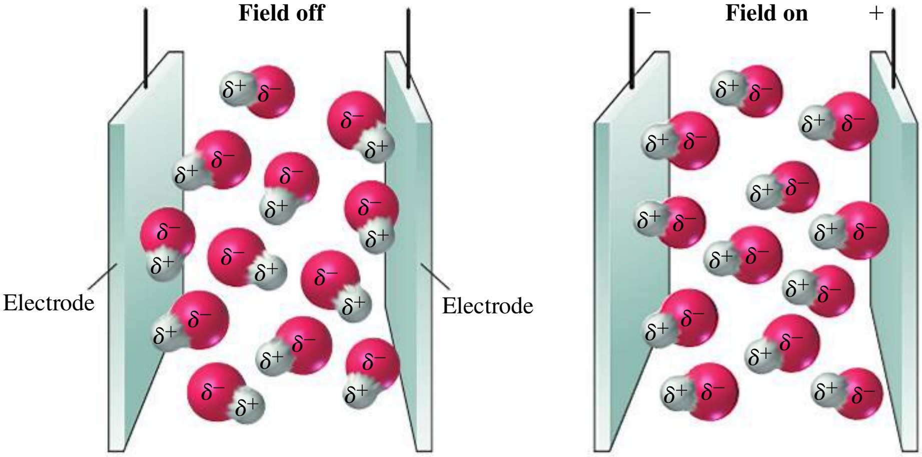
Let us recall some facts that we learned about polar covalent bonds in Section 10-3. In the HCl molecule, the Cl atom is more electronegative than the H atom. Electrons are displaced toward the Cl atom, as shown in the electrostatic potential map in the margin. The HCl molecule is a **polar molecule**. In the representation below, we use a cross-base arrow ($\longleftrightarrow$) that points to the atom that attracts electrons more strongly.

$$^{\delta+}\mathrm{H} \longleftrightarrow \mathrm{Cl}^{\delta-}$$

The extent of the charge displacement in a polar covalent bond is given by the **dipole moment**, μ. The dipole moment is the product of a partial charge (δ) and distance (d).

$$\mu = \delta \times d \tag{10.25}$$

If the product, $\delta \times d$, has a value of 3.34×10^{-30} coulomb · meter (C · m), the dipole moment, μ, has a value called 1 *debye*, D (pronounced duh-bye). One experimental method of determining dipole moments is based on the behavior of polar molecules in an electric field, suggested in Figure 10-14.



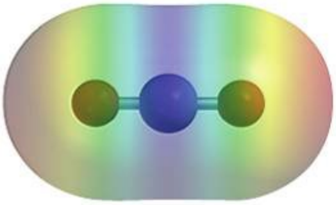
▲ FIGURE 10-14
Polar molecules in an electric field
The device pictured is called an electrical condenser (or capacitor). It consists of a pair of electrodes separated by a medium that does not conduct electricity but consists of polar molecules. (a) When the field is off, the molecules orient randomly. (b) When the electric field is turned on, the polar molecules orient in the field between the charged plates so that the negative ends of the molecules are toward the positive plate and vice versa.

The polarity of the H—Cl bond, as demonstrated on page 402, involves a shift of the electron charge density toward the Cl atom, and this produces a separation of the centers of positive and negative charge. Suppose, instead of a shift in electron charge density, we think of an equivalent situation—the transfer of a *fraction* of the charge of an electron from the H atom to the Cl atom through the entire internuclear distance. Let us determine the magnitude of this partial charge, δ. To do this, we need the measured dipole moment, 1.03 D; the H—Cl bond length, 127.4 pm; and equation (10.25) rearranged to

$$\delta = \frac{\mu}{d} = \frac{1.03\ \text{D} \times 3.34 \times 10^{-30}\ \text{C}\cdot\text{m/D}}{127.4 \times 10^{-12}\ \text{m}} = 2.70 \times 10^{-20}\ \text{C}$$

This charge is about 17% of the charge on an electron (1.602×10^{-19} C) and suggests that HCl is about 17% ionic. This assessment of the percent ionic character of the H—Cl bond agrees well with the 20% we made based on electronegativity differences (recall Example 10-4).

CO_2. Carbon dioxide molecules are *nonpolar*. To understand this observation, we need to distinguish between the displacement of electron charge density in a particular bond and in the molecule as a whole. The electronegativity difference between C and O causes a displacement of electron charge density toward the O atom in each carbon-to-oxygen bond and gives rise to a *bond dipole*. However, because the two bond dipoles are equal in magnitude and point in opposite directions, they cancel each other and lead to a *resultant* dipole moment of zero for the molecule. The symmetrical nature of the electron charge density is clear in the electrostatic potential map for CO_2 shown in the margin.



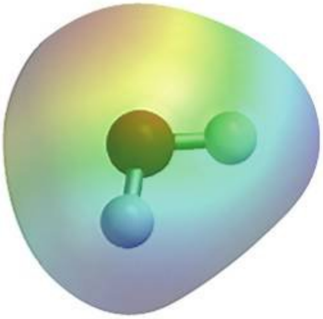
▲ **Electrostatic potential map of carbon dioxide**

$\mu = 0$

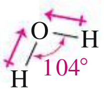
The fact that CO_2 is nonpolar is experimental proof that the three atoms in the molecule lie along a straight line in the order O—C—O. Of course, we can also predict that CO_2 is a linear molecule with the VSEPR theory, based on the Lewis structure

$$:\ddot{O}{=}C{=}\ddot{O}:$$

H_2O. Water molecules are *polar*. They have bond dipoles because of the electronegativity difference between H and O, and the bond dipoles combine to produce a resultant dipole moment of 1.84 D. The electrostatic potential map for water provides visual evidence of a net dipole moment on the water molecule. The molecule cannot be linear, for this would lead to a cancellation of bond dipoles, just as with CO_2. We have predicted with the VSEPR theory that the H_2O molecule is bent, and the observation that it is a polar molecule simply confirms the prediction.



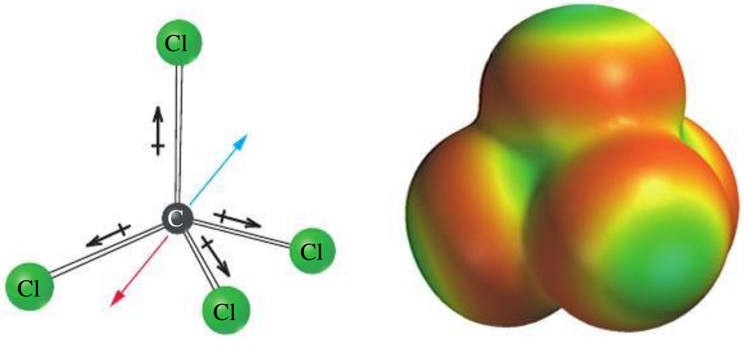
▲ **Electrostatic potential map of water**



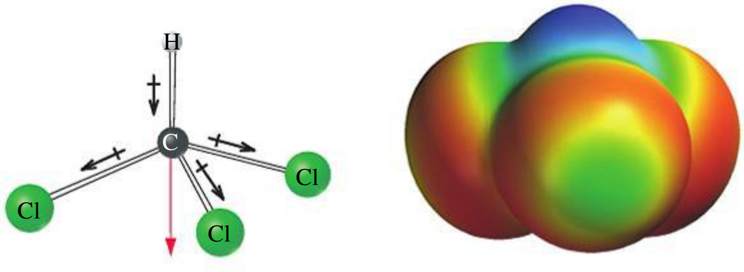
CCl_4. Carbon tetrachloride molecules are *nonpolar*. Based on the electronegativity difference between Cl and C, we expect a bond dipole for the C—Cl bond. The fact that the resultant dipole moment is *zero* means that the bond dipoles must be oriented in such a way that they cancel. The tetrahedral molecular geometry of CCl_4 provides the symmetrical distribution of bond dipoles that leads to this cancellation, as shown in Figure 10-15(a). Can you see that the molecule will be polar if one of the Cl atoms is replaced by an atom with a different electronegativity, say H? In the molecule, $CHCl_3$, there is a resultant dipole moment (Fig. 10-15b).

KEEP IN MIND

that the lack of a molecular dipole moment cannot distinguish between the two possible molecular geometries: tetrahedral and square planar. To do this, other experimental evidence, such as X-ray diffraction, is required.



(a) CCl_4: a nonpolar molecule



(b) $CHCl_3$: a polar molecule

▶ FIGURE 10-15

Molecular shapes and dipole moments

(a) The resultant of two of the C—Cl bond dipoles is shown as a red arrow, and that of the other two, as a blue arrow. The red and blue arrows point in opposite directions and cancel. The CCl_4 molecule is nonpolar. The balance of the charge distribution in CCl_4 is clearly seen in the electrostatic potential map. (b) The individual bond dipoles do combine to yield a resultant dipole moment (red arrow) of 1.04 D. The electrostatic potential map indicates that the hydrogen atom has a partial positive charge.

EXAMPLE 10-13 Determining the Relationship Between Geometric Shapes and the Resultant Dipole Moments of Molecules

Which of these molecules would you expect to be polar: Cl_2, ICl, BF_3, NO, SO_2?

Analyze

We will use the methods described above to determine the shape of the molecule, and then ascertain whether or not bond dipoles, if present, produce a net permanent dipole moment.

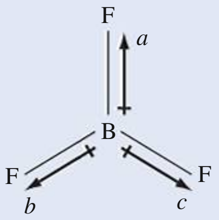
Solve

Polar: ICl, NO, SO_2. ICl and NO are diatomic molecules with an electronegativity difference between the bonded atoms. SO_2 is a bent molecule with an electronegativity difference between the S and O atoms.

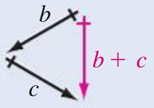
Nonpolar: Cl_2 and BF_3. Cl_2 is a diatomic molecule of identical atoms; hence no electronegativity difference. For BF_3, refer to Table 10.1. BF_3 is a symmetrical planar molecule (120° bond angles). The B—F bond dipoles cancel each other.

Assess

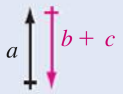
Bond dipoles are vector quantities. When adding them together, we must add them as vectors, that is, "head-to-tail," as illustrated below.



The bond dipoles are labeled *a*, *b*, and *c*.



Add *b* and *c* "head-to-tail" to form the vector sum *b* + *c*.



The vector sum of *a* and *b* + *c* is a vector of zero length (no dipole).

PRACTICE EXAMPLE A: Only one of the following molecules is polar. Which is it, and why? SF_6, H_2O_2, C_2H_4.

PRACTICE EXAMPLE B: Only one of the following molecules is *nonpolar*. Which is it, and why? Cl_3CCH_3, PCl_5, CH_2Cl_2, NH_3.

10-10 CONCEPT ASSESSMENT

The molecule NH_3 has the dipole moment $\mu = 1.47$ D, whereas for the similar molecule NF_3, $\mu = 0.24$ D. Why do you suppose there is such a large difference in these two values? [*Hint:* What is the effect of the lone-pair electrons on the N atom?]

10-8 Bond Order and Bond Lengths

The term **bond order** describes whether a covalent bond is *single* (bond order = 1), *double* (bond order = 2), or *triple* (bond order = 3). Think of electrons as the "glue" that binds atoms together in covalent bonds. The higher the bond order—that is, the more electrons present—the more glue and the more tightly the atoms are held together.

Bond length is the distance between the centers of two atoms joined by a covalent bond. A double bond between atoms is shorter than a single bond, and a triple bond is shorter still. You can see this relationship clearly in Table 10.2 by comparing the three different bond lengths for the nitrogen-to-nitrogen bond. For example, the measured length of the nitrogen-to-nitrogen triple bond in N_2 is 109.8 pm, whereas the nitrogen-to-nitrogen single bond in hydrazine, $H_2N{-}NH_2$, is 147 pm.

Perhaps you can now also better understand the meaning of covalent radius that we introduced in Section 9-3. The single covalent radius is one-half the distance between the centers of identical atoms joined by a *single* covalent bond. Thus, the single covalent radius of chlorine in Figure 9-9 (99 pm) is one-half the bond length given in Table 10.2, that is, $\frac{1}{2} \times 199$ pm. Furthermore, as a rough generalization,

> the length of the covalent bond between two atoms can be approximated as the sum of the covalent radii of the two atoms.

Some of these ideas about bond length are applied in Example 10-14.

TABLE 10.2 Some Average Bond Lengths[a]

Bond	Bond Length, pm	Bond	Bond Length, pm	Bond	Bond Length, pm
H—H	74.14	C—C	154	N—N	145
H—C	110	C═C	134	N═N	123
H—N	100	C≡C	120	N≡N	109.8

H—Br	141.4	C═O	120	F—F	143
H—I	160.9	C—Cl	178	Cl—Cl	199
				Br—Br	228
				I—I	266

[a] Most values (C—H, N—H, C—H, and so on) are averaged over a number of species containing the indicated bond and may vary by a few picometers. Where a diatomic molecule exists, the value given is the actual bond length in that molecule (H_2, N_2, HF, and so on) and is known more precisely.

EXAMPLE 10-14 Estimating Bond Lengths

Provide the best estimate you can of these bond lengths for the **(a)** the nitrogen-to-hydrogen bonds in NH_3: **(b)** the bromine-to-chlorine bond in BrCl.

Analyze

If no bond length is listed for a particular bond, A—B, then look up the bond lengths for A—A and B—B. The A—B bond length can then be estimated as one-half the A—A bond length plus one-half the B—B bond length.

Solve

(a) The Lewis structure of ammonia (page 400) shows the nitrogen-to-hydrogen bonds as single bonds. The value listed in Table 10.2 for the N—H bond is 100 pm, so this is the value we would predict. (The measured N—H bond length in NH_3 is 101.7 pm.)

(b) There is no bromine-to-chlorine bond length in Table 10.2, so we need to calculate an approximate bond length using the relationship between bond length and covalent radii. BrCl contains a Br—Cl *single* bond [imagine substituting one Br atom for one Cl atom in structure (10.4)]. The length of the Br—Cl bond is one-half the Cl—Cl bond length *plus* one-half the Br—Br bond length: $\left(\frac{1}{2} \times 199\text{ pm}\right) + \left(\frac{1}{2} \times 228\text{ pm}\right) = 214\text{ pm}$. (The measured bond length is 213.8 pm.)

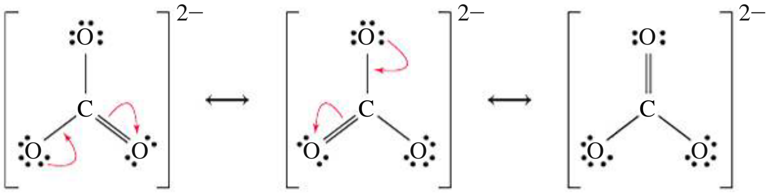
Assess

The data in Table 10.2 can be used to make estimates of bond lengths in a variety of molecules.

PRACTICE EXAMPLE A: Estimate the bond lengths of the carbon-to-hydrogen bonds and the carbon-to-bromine bond in CH_3Br.

PRACTICE EXAMPLE B: In the thiocyanate ion, SCN^-, the length of the carbon-to-nitrogen bond is 115 pm. Write a plausible Lewis structure for this ion and describe its geometric shape.

An interesting situation arises for molecules in which resonance is present. In such molecules, fractional bond orders are possible. Consider, for example, the carbonate anion, CO_3^{2-}, shown below.



Each resonance form has one double bond and two single bonds. Because the actual structure of the carbonate anion is an average of these three structures, the average bond order is $\frac{1}{3}(1 + 1 + 2) = 1\frac{1}{3}$. The CO bond distance in the carbonate anion is 129 pm, which is intermediate between a C—O single bond (143 pm) and a C═O double bond (120 pm), as we might expect for a fractional bond order.

10-11 CONCEPT ASSESSMENT

NO_2^- and NO_2^+ are made up of the same atoms. How would you expect the nitrogen-to-oxygen bond lengths in these two ions to compare?

10-9 Bond Energies

Together with bond lengths, bond energies can be used to assess the suitability of a proposed Lewis structure. Bond energy, bond length, and bond order are interrelated properties in this sense: the higher the bond order, the shorter the bond between two atoms and the greater the bond energy.

Energy is *released* when isolated atoms join to form a covalent bond, and energy must be *absorbed* to break apart covalently bonded atoms. **Bond-dissociation energy**, *D*, is the quantity of energy required to break one mole of covalent bonds in a *gaseous* species. The SI units are kilojoules per mole of bonds (kJ/mol).

We can think of bond-dissociation energy as an enthalpy change or a heat of reaction, as discussed in Chapter 7. For example,

$$\textit{Bond breakage:}\quad H_2(g) \longrightarrow 2\,H(g) \qquad \Delta H = D(H{-}H) = +435.93\ \text{kJ/mol}$$

$$\textit{Bond formation:}\quad 2\,H(g) \longrightarrow H_2(g) \qquad \Delta H = -D(H{-}H) = -435.93\ \text{kJ/mol}$$

It is not hard to picture the meaning of bond energy for a diatomic molecule, because there is only one bond in the molecule. It is also not difficult to see that the bond-dissociation energy of a diatomic molecule can be expressed rather precisely, as is that of $H_2(g)$. With a polyatomic molecule, such as H_2O, the situation is different (Fig. 10-16). The energy needed to dissociate one mole of H atoms by breaking one O—H bond per H_2O molecule,

$$H{-}OH(g) \longrightarrow H(g) + OH(g) \qquad \Delta H = D(H{-}OH) = +498.7\ \text{kJ/mol}$$

is different from the energy required to dissociate one mole of H atoms by breaking the bonds in OH(g):

$$O{-}H(g) \longrightarrow H(g) + O(g) \qquad \Delta H = D(O{-}H) = +428.0\ \text{kJ/mol}$$

The two O—H bonds in H_2O are identical; therefore, they should have identical energies. This energy, which we can call the O—H bond energy in H_2O, is the *average* of the two values listed above: 463.4 kJ/mol. The O—H bond energy in other molecules containing the OH group will be somewhat different from that in H—O—H. For example, in methanol, CH_3OH, the O—H bond-dissociation energy, which we can represent as $D(H{-}OCH_3)$, is 436.8 kJ/mol. The usual method of tabulating bond energies (Table 10.3) is as *averages*. An **average bond energy** is the average of bond-dissociation energies for a number of different species containing the particular bond. Understandably, average bond energies cannot be stated as precisely as specific bond-dissociation energies.

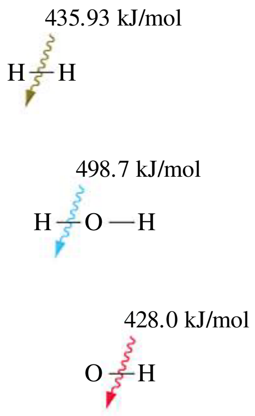
As you can see from Table 10.3, double bonds have higher bond energies than do single bonds between the same atoms, but they are *not* twice as large. Triple bonds are stronger still, but their bond energies are *not* three times as

TABLE 10.3 Some Average Bond Energies[a]

Bond	Bond Energy, kJ/mol	Bond	Bond Energy, kJ/mol	Bond	Bond Energy, kJ/mol
H—H	436	C—C	347	N—N	163
H—C	414	C═C	611	N═N	418
H—N	389	C≡C	837	N≡N	946
H—O	464	C—N	305	N—O	222
H—S	368	C═N	615	N═O	590
H—F	565	C≡N	891	O—O	142
H—Cl	431	C—O	360	O═O	498
H—Br	364	C═O	736[b]	F—F	159
H—I	297	C—Cl	339	Cl—Cl	243
				Br—Br	193
				I—I	151

[a] Although all data are listed with about the same precision (three significant figures), some values are actually known more precisely. Specifically, the values for the diatomic molecules H_2, HF, HCl, HBr, HI, N_2 (N≡N), O_2 (O═O), F_2, Cl_2, Br_2, and I_2 are actually bond-dissociation energies, rather than average bond energies.

[b] The value for the C═O bonds in CO_2 is 799 kJ/mol.



▲ FIGURE 10-16
Some bond energies compared
The same quantity of energy, 435.93 kJ/mol, is required to break all H—H bonds. In H_2O, more energy is required to break the first bond (498.7 kJ/mol) than to break the second (428.0 kJ/mol). The second bond broken is that in the OH radical. The O—H bond energy in H_2O is the average of the two values: 463.4 kJ/mol.

KEEP IN MIND

that tabulated bond energies are for isolated molecules in the gaseous state. They do not apply to molecules in close contact in liquids and solids.

large as single bonds between the same atoms. This observation about bond order and bond energy will seem quite reasonable after multiple bonds are more fully described in the next chapter.

Bond energies also have some interesting uses in thermochemistry. For a reaction involving *gases*, visualize the process

$$\text{gaseous reactants} \longrightarrow \text{gaseous atoms} \longrightarrow \text{gaseous products}$$

In this hypothetical process, we first break all the bonds in reactant molecules and form gaseous atoms. For this step, the enthalpy change is $\Delta H\,(\text{bond breakage}) = \Sigma\text{BE}\,(\text{reactants})$, where BE stands for bond energy. Next, we allow the gaseous atoms to recombine into product molecules. In this step, bonds are formed and $\Delta H\,(\text{bond formation}) = -\Sigma\text{BE}\,(\text{products})$. The enthalpy change of the reaction, then, is

$$\begin{aligned}\Delta H &= \Delta H\,(\text{bond breakage}) + \Delta H\,(\text{bond formation})\\ &\approx \Sigma\text{BE}\,(\text{reactants}) - \Sigma\text{BE}\,(\text{products})\end{aligned} \qquad \textbf{(10.26)}$$

The approximately equal sign ($\approx$) in expression (10.26) signifies that some of the bond energies used are likely to be *average* bond energies rather than true bond-dissociation energies. Also, a number of terms often cancel out because some of the same types of bonds appear in the products as in the reactants. We can base the calculation of ΔH just on the *net* number and types of bonds broken and formed, as illustrated in Example 10-15.

KEEP IN MIND

that the difference in equation (10.26) is calculated as reactants minus products and not products minus reactants.

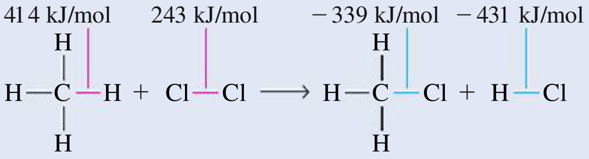
EXAMPLE 10-15 Calculating an Enthalpy of Reaction from Bond Energies

The reaction of methane (CH_4) and chlorine produces a mixture of products called chloromethanes. One of these is monochloromethane, CH_3Cl, used in the preparation of silicones. Calculate ΔH for the reaction

$$CH_4(g) + Cl_2(g) \longrightarrow CH_3Cl(g) + HCl(g)$$

Analyze

To identify which bonds are broken and formed, it helps to draw structural formulas (or Lewis structures), as in Figure 10-17. To apply expression (10.26) literally, we would break *four* C—H bonds and *one* Cl—Cl bond and form *three* C—H bonds, *one* C—Cl bond, and *one* H—Cl bond. The *net* change, however, is the breaking of *one* C—H bond and *one* Cl—Cl bond, followed by the formation of *one* C—Cl bond and *one* H—Cl bond.



▲ FIGURE 10-17
Net bond breakage and formation in a chemical reaction—Example 10-15 illustrated
Bonds that are broken are shown in red and bonds that are formed, in blue. Bonds that remain unchanged are black. The net change is that *one* C—H and *one* Cl—Cl bond break and *one* C—Cl and *one* H—Cl bond form.

Solve

ΔH for net bond breakage:	1 mol C—H bonds	+414 kJ
	1 mol Cl—Cl bonds	+243 kJ
	sum:	+657 kJ
ΔH for net bond formation:	1 mol C—Cl bonds	−339 kJ
	1 mol H—Cl bonds	−431 kJ
	sum:	−770 kJ
Enthalpy of reaction:	$\Delta H = 657 - 770 =$	−113 kJ

Assess

A number of terms cancel out because some of the same types of bonds appear in both reactants and products. Such a situation is not uncommon.

PRACTICE EXAMPLE A: Use bond energies to estimate the enthalpy change for the reaction

$$2\,H_2(g) + O_2(g) \longrightarrow 2\,H_2O(g)$$

PRACTICE EXAMPLE B: Use bond energies to estimate the enthalpy of formation of $NH_3(g)$.

In Chapter 7, we learned how to calculate ΔH for any reaction using ΔH_f° values—see equation (7.21). Equation (10.26) gives us another way to calculate ΔH for a gas-phase reaction. There is no advantage to using bond energies over enthalpy-of-formation data. Enthalpies of formation are generally known rather precisely, whereas bond energies are only average values. But when enthalpy-of-formation data are lacking, bond energies can prove particularly useful.

Another way to use bond energies is in predicting whether a reaction will be *endothermic* or *exothermic*. In general, if

$$\underset{\text{(reactants)}}{\text{weak bonds}} \longrightarrow \underset{\text{(products)}}{\text{strong bonds}} \qquad \Delta H < 0 \qquad \text{(exothermic)}$$

and

$$\underset{\text{(reactants)}}{\text{strong bonds}} \longrightarrow \underset{\text{(products)}}{\text{weak bonds}} \qquad \Delta H > 0 \qquad \text{(endothermic)}$$

Example 10-16 applies this idea to a reaction involving highly reactive, unstable species for which enthalpies of formation are not normally listed.

EXAMPLE 10-16 Using Bond Energies to Predict Exothermic and Endothermic Reactions

One of the steps in the formation of monochloromethane (Example 10-15) is the reaction of a gaseous chlorine *atom* (a chlorine radical) with a molecule of methane. The products are an unstable methyl radical and HCl(g). Is this reaction endothermic or exothermic?

$$CH_4 + \cdot Cl(g) \longrightarrow \cdot CH_3(g) + HCl(g)$$

Analyze

In the reaction, one C—H bond is broken for every H—Cl bond formed. Thus, we must compare the bond energies for the C—H and H—Cl bonds to decide whether the reaction is endothermic or exothermic.

Solve

For every molecule of CH_4 that reacts, *one* C—H bond *breaks*, requiring 414 kJ per mole of bonds; and *one* H—Cl bond *forms*, releasing 431 kJ per mole of bonds. Because more energy is released in forming new bonds than is absorbed in breaking old ones, we predict that the reaction is exothermic.

Assess

In the example above, we had to break only C—H bonds and form only H—Cl bonds. Most reactions involve breaking and forming several types of bonds, and so it is usually not obvious whether the reaction will be exothermic or endothermic. In such cases, we must calculate ΔH, by using equation (10.26), to see whether $\Delta H > 0$ or $\Delta H < 0$.

PRACTICE EXAMPLE A: Is the following reaction endothermic or exothermic?

$$CH_3COCH_3(g) + H_2(g) \longrightarrow (CH_3)_2CH(OH)(g)$$

PRACTICE EXAMPLE B: Predict whether the following reaction should be exothermic or endothermic:

$$H_2O(g) + Cl_2(g) \longrightarrow \frac{1}{2}O_2(g) + 2\,HCl(g).$$

MasteringCHEMISTRY www.masteringchemistry.com

It is almost a certainty that you are familiar with microwave radiation—have you ever cooked or heated food in a microwave oven? Microwave radiation plays a prominent role in a branch of science called rotational (or microwave) spectroscopy. For a discussion of rotational spectroscopy and how it is used not only to make precise measurements of bond lengths but also to detect molecules in interstellar space, go to the Focus On feature for Chapter 10, Molecules in Space: Measuring Bond Lengths, on the MasteringChemistry site.

Summary

10-1 Lewis Theory: An Overview—A **Lewis symbol** represents the valence electrons of an atom by using dots placed around the chemical symbol. A **Lewis structure** is a combination of Lewis symbols used to represent chemical bonding. Normally, all the electrons in a Lewis structure are paired, and each atom in the structure acquires an **octet**—that is, there are eight electrons in the valence shell. In **Lewis theory**, chemical bonds are classified as **ionic bonds**, which are formed by electron transfer between atoms, or **covalent bonds**, which are formed by electrons shared between atoms. Most bonds, however, have partial ionic and partial covalent characteristics.

10-2 Covalent Bonding: An Introduction—Atoms in molecules are often surrounded by eight valence-shell electrons (an octet) and thus conform to the **octet rule**. In covalent bonds, pairs of electrons shared between two atoms to form the bonds are called **bond pairs**, while pairs of electrons not shared in a chemical bond are called **lone pairs**. A single pair of electrons shared between two atoms constitutes a **single covalent bond**. When both electrons in a covalent bond between two atoms are provided by only one of the atoms, the bond is called a **coordinate covalent bond**. To construct a Lewis structure for a molecule in which all atoms obey the octet rule, it is often necessary for atoms to share more than one pair of electrons, thus forming **multiple covalent bonds**. Two shared electron pairs constitute a **double covalent bond** and three shared pairs a **triple covalent bond**.

10-3 Polar Covalent Bonds and Electrostatic Potential Maps—A covalent bond in which the electron pair is not shared equally by the bonded atoms is called a **polar covalent bond**. Whether a bond is polar or not can be predicted by comparing the **electronegativity (EN)** of the atoms involved (Fig. 10-6). The greater the **electronegativity difference** (Δ**EN**) between two atoms in a chemical bond, the more polar the bond and the more ionic its character. The electron charge distribution in a molecule can be visualized by computing an **electrostatic potential map** (Figs. 10-4 and 10-5). The variation of charge in the molecule is represented by a color spectrum in which red is the most negative and blue the most positive. Electrostatic potential maps are a powerful way of representing electron charge distribution in both polar and nonpolar molecules.

10-4 Writing Lewis Structures—To draw the Lewis structure of a covalent molecule, one needs to know the **skeletal structure**—that is, which is the **central atom** and what atoms are bonded to it. Atoms that are bonded to just one other atom are called **terminal atoms** (structure 10.13). Typically, the atom with the lowest electronegativity is a central atom. At times, the concept of **formal charge** (expression 10.16) is useful in selecting a skeletal structure and assessing the plausibility of a Lewis structure.

10-5 Resonance—Often, more than one plausible Lewis structure can be written for a species; this situation is called **resonance**. In these cases the true structure is a resonance hybrid of two or more contributing structures.

10-6 Exceptions to the Octet Rule—There are often exceptions to the octet rule. (1) Odd-electron species, such as NO, have an unpaired electron and are paramagnetic. Many of these species are reactive molecular fragments, such as OH, called **free radicals**. (2) A few molecules have incomplete octets in their Lewis structures, that is, not enough electrons to provide an octet for every atom. (3) **Expanded valence shells** occur in some compounds of nonmetals of the third period and beyond. In these, the valence shell of the central atom must be expanded to 10 or 12 electrons in order to write a Lewis structure.

10-7 Shapes of Molecules—A powerful method for predicting the **molecular geometry**, or molecular shape, of a species is the **valence-shell electron-pair repulsion theory** (**VSEPR**). The shape of a molecule or polyatomic ion depends on the geometric distribution of valence-shell electron groups—the **electron-group geometry**—and whether these groups contain bonding electrons or lone pairs (Fig. 10-11, Table 10.1). The angles between the electron groups provide a method for predicting **bond angles** in a molecule. An important use of information about the shapes of molecules is in establishing whether bonds in a molecule combine to produce a resultant **dipole moment** (Fig. 10-15). Molecules with a resultant dipole moment are **polar molecules**; those with no resultant dipole moment are nonpolar.

10-8 Bond Order and Bond Lengths—Single, double, and triple covalent bonds are said to have a **bond order** of 1, 2, and 3, respectively. **Bond length** is the distance between the centers of two atoms joined by a covalent bond. The greater the bond order, the shorter the bond length (Table 10.2).

10-9 Bond Energies—**Bond-dissociation energy**, D, is the quantity of energy required to break one mole of covalent bonds in a gaseous molecule. **Average bond energies** (Table 10.3) can be used to estimate enthalpy changes for reactions involving gases.

Integrative Example

Nitryl fluoride is a reactive gas useful in rocket propellants. Its mass percent composition is 21.55% N, 49.23% O, and 29.23% F. Its density is 2.7 g/L at 20 °C and 1.00 atm pressure. Describe the nitryl fluoride molecule as completely as possible—that is, its formula, Lewis structure, molecular shape, and polarity.

Analyze

First, determine the empirical formula of nitryl fluoride from the composition data and the molar mass based on that formula. Next, determine the true molar mass from the vapor density data. Now the two results can be compared to establish the molecular formula. Then, write a plausible Lewis structure based on the molecular formula, and apply VSEPR theory to the Lewis structure to predict the molecular shape. Finally, assess the polarity of the molecule from the molecular shape and electronegativity values.

Solve

To determine the empirical formula, use the method of Example 3-5 (page 80). In 100.0 g of the compound,

$$\text{mol N} = 21.55\ \text{g N} \times \frac{1\ \text{mol N}}{14.007\ \text{g N}} = 1.539\ \text{mol N}$$

$$\text{mol O} = 49.23\ \text{g O} \times \frac{1\ \text{mol O}}{15.999\ \text{g O}} = 3.077\ \text{mol O}$$

$$\text{mol F} = 29.23\ \text{g F} \times \frac{1\ \text{mol F}}{18.998\ \text{g F}} = 1.539\ \text{mol F}$$

The empirical formula is

$$N_{1.539}O_{3.077}F_{1.539} = NO_2F$$

The molar mass based on this formula is

$$14 + 32 + 19 = 65\ \text{g/mol}$$

Use the method of Example 6-7 (page 208) to determine the molar mass of the gas.

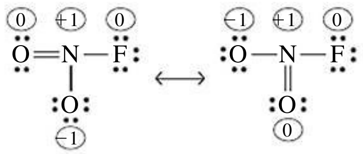
$$\text{molar mass} = \frac{mRT}{PV} = \frac{dRT}{P}$$

$$= \frac{2.7\ \text{g/L} \times 0.0821\ \text{L atm mol}^{-1}\ \text{K}^{-1} \times 293\ \text{K}}{1.00\ \text{atm}}$$

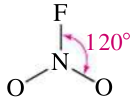
$$= 65\ \text{g/mol}$$

Because the two molar mass results are the same, the molecular and empirical formulas are the same: NO_2F.

Because N has the lowest electronegativity, it should be the lone central atom in the Lewis structure. There are two equivalent contributing structures to a resonance hybrid.



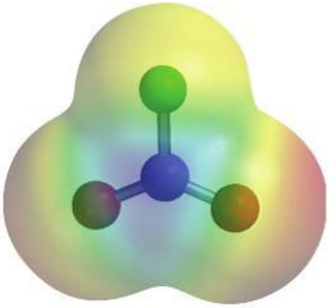
Three electron groups around the N atom produce a trigonal planar electron-group geometry. All the electron groups participate in bonding, so the molecular geometry is also trigonal planar. The predicted bond angles are 120°. (The experimentally determined F—N—O bond angle is 118°.)



The molecule has a symmetrical shape, but because the electronegativity of F is different from that of O, we should expect the electron charge distribution in the molecule to be nonsymmetrical, leading to a small resultant dipole moment. NO_2F is a polar molecule.

Assess

In the contributing structures to the resonance hybrid Lewis structure, the F atom has a formal charge of zero and the two O atoms have an average formal charge of $-\frac{1}{2}$. As a result, we might expect the oxygen-atom region of the molecule to be the most negative in electron charge density and the fluorine region to be more neutral. This conclusion is confirmed by the electrostatic potential map for NO_2F. Notice also the positive charge



density around the nitrogen nucleus, which is in accord with the fact that the nitrogen is the least electronegative of the three elements.

PRACTICE EXAMPLE A: Phosphorus pentachloride, $PCl_5(g)$, can be made from the reaction of $PCl_3(g)$ and $Cl_2(g)$. By using only data from Appendix D, estimate the average bond energy for the P—Cl bond. Assume that the P—Cl bond energies are the same in PCl_3 and PCl_5. With reference to the geometries of PCl_3 and PCl_5, explain why the P—Cl bond energies are probably not the same in these two molecules.

PRACTICE EXAMPLE B: The condensed structural formulas of formamide and formaldoxime are H_2NCHO and H_2CNOH, respectively. One of these molecules is much more stable than the other. **(a)** Sketch the structures of these molecules, using dash and wedge symbols, indicate the various bond angles, and use bond energies to determine which molecule is more stable. **(b)** Experiment shows that the H—N—H angle in formamide is 119° and the N—C—O angle is 124°. Draw a Lewis structure for formamide that is consistent with this structural information.

Exercises

Lewis Theory

1. Write Lewis symbols for the following atoms. **(a)** Kr; **(b)** Ge; **(c)** N; **(d)** Ga; **(e)** As; **(f)** Rb.
2. Write Lewis symbols for the following ions. **(a)** H^-; **(b)** Sn^{2+}; **(c)** K^+; **(d)** Br^-; **(e)** Se^{2-}; **(f)** Sc^{3+}.
3. Write plausible Lewis structures for the following molecules that contain only single covalent bonds. **(a)** FCl; **(b)** I_2; **(c)** SF_2; **(d)** NF_3; **(e)** H_2Te.
4. Each of the following molecules contains at least one multiple (double or triple) covalent bond. Give a plausible Lewis structure for **(a)** OCS; **(b)** CH_3CHO; **(c)** F_2CO; **(d)** Cl_2SO; **(e)** C_2H_2.
5. By means of Lewis structures, represent bonding between the following pairs of elements: **(a)** Cs and Br; **(b)** H and Sb; **(c)** B and Cl; **(d)** Cs and Cl; **(e)** Li and O; **(f)** Cl and I. Your structures should show whether the bonding is essentially ionic or covalent.
6. Which of the following have Lewis structures that *do not* obey the octet rule: NF_3, $AlCl_3$, $SiF_6{}^{2-}$, SO_3, $PH_4{}^+$, $PO_4{}^{3-}$, ClO_2?
7. Give several examples for which the following statement proves to be incorrect. "All atoms in a Lewis structure have an octet of electrons in their valence shells."
8. Suggest reasons why the following do not exist as stable molecules: **(a)** H_3; **(b)** HHe; **(c)** He_2; **(d)** H_3O.
9. Describe what is wrong with each of the following Lewis structures.

   (a) $\mathrm{H-H-\overset{\cdot\cdot}{N}-\overset{\cdot\cdot}{\underset{\cdot\cdot}{O}}-H}$

   (b) $\mathrm{Ca-\overset{\cdot\cdot}{\underset{\cdot\cdot}{O}}:}$

10. Describe what is wrong with each of the following Lewis structures.

    (a) $\mathrm{:\overset{\cdot\cdot}{\underset{\cdot\cdot}{O}}-\overset{\cdot\cdot}{\underset{\cdot\cdot}{Cl}}-\overset{\cdot\cdot}{\underset{\cdot\cdot}{O}}:}$

    (b) $\mathrm{[\cdot\overset{\cdot}{C}=\overset{\cdot\cdot}{N}:]^-}$

11. Only one of the following Lewis structures is correct. Select that one and indicate the errors in the others.

    (a) cyanate ion $\mathrm{[:\overset{\cdot\cdot}{\underset{\cdot\cdot}{O}}-C=\overset{\cdot\cdot}{N}:]^-}$

    (b) carbide ion $\mathrm{[C\equiv C:]^{2-}}$

    (c) hypochlorite ion $\mathrm{[:\overset{\cdot\cdot}{\underset{\cdot\cdot}{Cl}}-\overset{\cdot\cdot}{\underset{\cdot\cdot}{O}}:]^-}$

    (d) nitrogen(II) oxide $\mathrm{:\overset{\cdot\cdot}{N}=\overset{\cdot\cdot}{O}:}$

12. Indicate what is wrong with each of the following Lewis structures. Replace each one with a more acceptable structure.

    (a) $\mathrm{Mg\ :\overset{\cdot\cdot}{\underset{\cdot\cdot}{O}}:}$

    (b) $\mathrm{[:\overset{\cdot\cdot}{\underset{\cdot\cdot}{O}}-\overset{\cdot}{N}=\overset{\cdot\cdot}{O}:]^+}$

    (c) $\mathrm{[:\overset{\cdot\cdot}{\underset{\cdot\cdot}{Cl}}]^+[:\overset{\cdot\cdot}{\underset{\cdot\cdot}{O}}:]^{2-}[\overset{\cdot\cdot}{\underset{\cdot\cdot}{Cl}}:]^+}$

    (d) $\mathrm{[:\overset{\cdot\cdot}{S}-C=\overset{\cdot\cdot}{N}:]^-}$

Ionic Bonding

13. Write Lewis structures for the following ionic compounds: **(a)** calcium chloride; **(b)** barium sulfide; **(c)** lithium oxide; **(d)** sodium fluoride.

14. Under appropriate conditions, both hydrogen and nitrogen can form monatomic anions. What are the Lewis symbols for these ions? What are the Lewis structures of the compounds **(a)** lithium hydride; **(b)** calcium hydride; **(c)** magnesium nitride?

15. Derive the correct formulas for the following ionic compounds by writing Lewis structures. **(a)** lithium sulfide; **(b)** sodium fluoride; **(c)** calcium iodide; **(d)** scandium chloride.

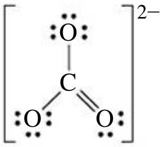
16. Each of the following ionic compounds consists of a combination of monatomic and polyatomic ions. Represent these compounds with Lewis structures. **(a)** $Al(OH)_3$; **(b)** $Ca(CN)_2$; **(c)** NH_4F; **(d)** $KClO_3$; **(e)** $Ba_3(PO_4)_2$.

Formal Charge

17. Assign formal charges to each of the atoms in the following structures.

(a) $[H—C{\equiv}C{:}]^-$

(b)



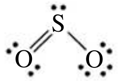
(c) $[CH_3—CH—CH_3]^+$

18. Assign formal charges to each of the atoms in the following structures.

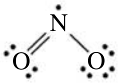
(a)

$:\ddot{\underset{..}{I}}—\ddot{\underset{..}{I}}:$

(b)



(c)



19. Both oxidation state and formal charge involve conventions for assigning valence electrons to bonded atoms in compounds, but clearly they are not the same. Describe several ways in which these concepts differ.

20. Although the notion that a Lewis structure in which formal charges are zero or held to a minimum seems to apply in most instances, describe several significant situations in which this appears not to be the case.

21. What is the formal charge of the indicated atom in each of the following structures?

(a) the central O atom in O_3
(b) Al in AlH_4^-
(c) Cl in ClO_3^-
(d) Si in SiF_6^{2-}
(e) Cl in ClF_3

22. Assign formal charges to the atoms in the following species, and then select the more likely skeletal structure.

(a) H_2NOH or H_2ONH
(b) SCS or CSS
(c) NFO or FNO
(d) $SOCl_2$ or $OSCl_2$ or OCl_2S
(e) F_3SN and F_3NS

23. The concept of formal charge helped us to choose the more plausible of the Lewis structures for NO_2^+ given in expressions (10.14) and (10.15). Can it similarly help us to choose a single Lewis structure as most plausible for CO_2H^+? Explain.

24. Show that the idea of minimizing the formal charges in a structure is at times in conflict with the observation that compact, symmetrical structures are more commonly observed than elongated ones with many central atoms. Use ClO_4^- as an illustrative example.

Lewis Structures

25. Write acceptable Lewis structures for the following molecules: **(a)** H_2NNH_2; **(b)** HOClO; **(c)** $(HO)_2SO$; **(d)** HOOH **(e)** SO_4^{2-}.

26. Two molecules that have the same formulas but different structures are said to be isomers. (In isomers, the same atoms are present but linked together in different ways.) Draw acceptable Lewis structures for *two* isomers of S_2F_2.

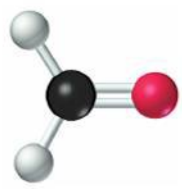
27. The following polyatomic anions involve covalent bonds between O atoms and the central nonmetal atom. Propose an acceptable Lewis structure for each. **(a)** SO_3^{2-}; **(b)** NO_2^-; **(c)** CO_3^{2-}; **(d)** HO_2^-.

28. Represent the following ionic compounds by Lewis structures: **(a)** barium hydroxide; **(b)** sodium nitrite; **(c)** magnesium iodate; **(d)** aluminum sulfate.

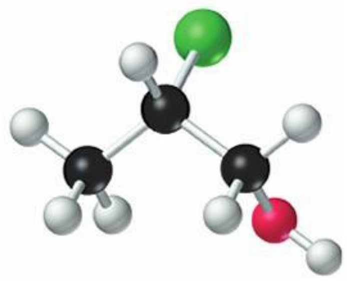
29. Write a plausible Lewis structure for crotonaldehyde, $CH_3CHCHCHO$, a substance used in tear gas and insecticides.

30. Write a plausible Lewis structure for C_3O_2, a substance known as carbon suboxide.

31. Write Lewis structures for the molecules represented by the following molecular models.

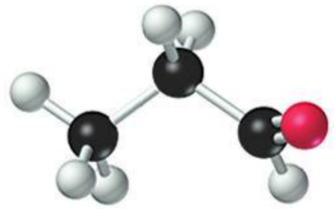


(a)

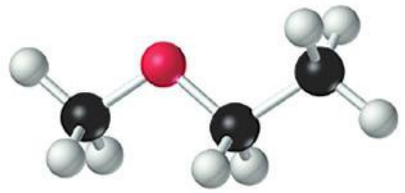


(b)

32. Write Lewis structures for the molecules represented by the following molecular models.



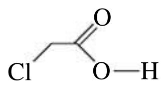
(a)



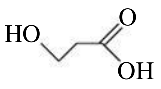
(b)

33. Write Lewis structures for the molecules represented by the following line-angle formulas. [*Hint:* Recall page 70 and Figure 3-2.]

(a)

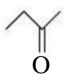


(b)



34. Write Lewis structures for the molecules represented by the following line-angle formulas. [*Hint:* Recall page 70 and Figure 3-2.]

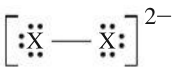
(a)



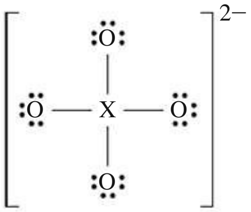
(b)

35. Identify the main group that the element X belongs to in each of the following Lewis structures. For the types of molecule shown, give an example that exists.

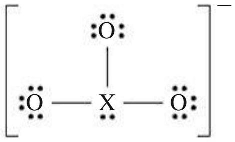
(a)



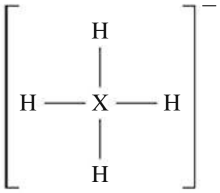
(b)



(c)



(d)

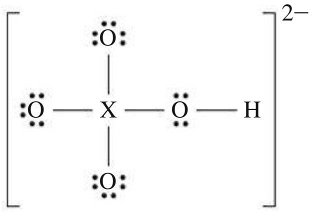


36. Identify the main group that the element X belongs to in each of the following Lewis structures. For the types of molecule shown, give an example that exists.

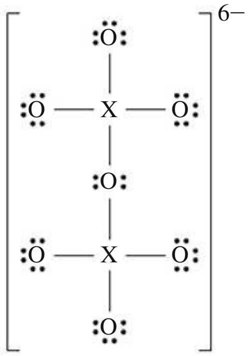
(a)

(b)

(c)



(d)



Polar Covalent Bonds and Electrostatic Potential Maps

37. Use your knowledge of electronegativities, but *do not* refer to tables or figures in the text, to arrange the following bonds in terms of *increasing* ionic character: C—H, F—H, Na—Cl, Br—H, K—F.

38. Which of the following molecules would you expect to have a resultant dipole moment (μ); **(a)** F_2, **(b)** NO_2, **(c)** BF_3, **(d)** HBr, **(e)** H_2CCl_2, **(f)** SiF_4, **(g)** OCS? Explain.

39. What is the percent ionic character of each of the following bonds: **(a)** S—H; **(b)** O—Cl; **(c)** Al—O; **(d)** As—O?

40. Plot the data of Figure 10-6 as a function of atomic number. Does the property of electronegativity conform to the periodic law? Do you think it should?

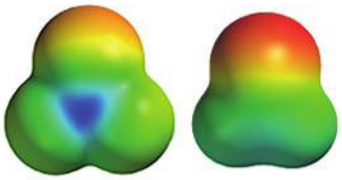
41. Use a cross-base arrow ($\longmapsto$) to represent the polarity of the bond in each of the following diatomic molecules. Then use the data below to calculate, in the manner described on page 431, the partial charges (δ) on the atoms in each molecule. Express the partial charges as a decimal fraction of the elementary charge, $e = 1.602 \times 10^{-19}$ C, for example $\delta = +0.17e$ or $\delta = -0.17e$.

	Bond Length, pm	Dipole Moment, D
ClF	162.8	0.8881
RbF	227.0	8.547
SnO	183.3	4.3210
BaO	194.0	7.954

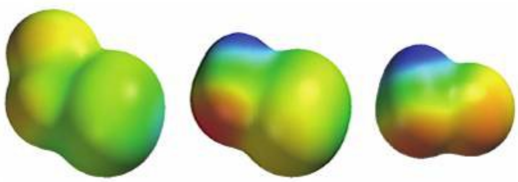
42. Use a cross-base arrow ($\longmapsto$) to represent the polarity of the bond in each of the following diatomic molecules. Then use the data below to calculate the partial charges (δ) on the atoms in each molecule. Express the partial charges in the manner described in Exercise 41.

	Bond Length, pm	Dipole Moment, D
OH	98.0	1.66
CH	131.1	1.46
CN	117.5	1.45
CS	194.4	1.96

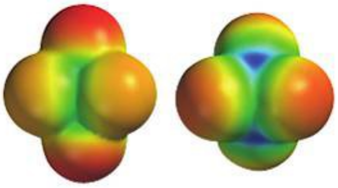
43. Which electrostatic potential map corresponds to $F_2C{=}O$, and which to $H_2C{=}O$?



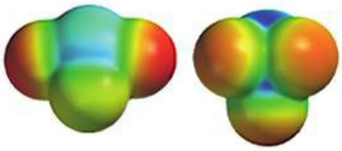
44. Match the correct electrostatic potential map corresponding to HOCl, FOCl, and HOF.



45. Two electrostatic potential maps are shown, one corresponding to a molecule containing only S and F, the other Si and F. Match them. What are the molecular formulas of the compounds?



46. Two electrostatic potential maps are shown, one corresponding to a molecule containing only Cl and F, the other P and F. Match them. What are the molecular formulas of the compounds?



Resonance

47. Through appropriate Lewis structures, show that the phenomenon of resonance is involved in the nitrite ion.

48. Which of the following species requires a resonance hybrid for its Lewis structure: **(a)** CO_2, **(b)** OCl^-, **(c)** CO_3^{2-}, or **(d)** OH^-? Explain.

49. Dinitrogen oxide (nitrous oxide, or "laughing gas") is sometimes used as an anesthetic. Here are some data about the N_2O molecule: N—N bond length = 113 pm; N—O bond length = 119 pm. Use these data and other information from the chapter to comment on the plausibility of each of the following Lewis structures shown. Are they all valid? Which ones do you think contribute most to the resonance hybrid?

$:\mathrm{N}\equiv\mathrm{N}-\underset{\cdot\cdot}{\ddot{\mathrm{O}}}:$

(a)

$:\ddot{\mathrm{N}}=\mathrm{N}=\ddot{\mathrm{O}}:$

(b)

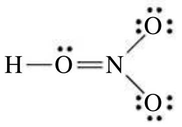
$:\underset{\cdot\cdot}{\ddot{\mathrm{N}}}-\mathrm{N}\equiv\mathrm{O}:$

(c)

$:\ddot{\mathrm{N}}=\mathrm{O}=\ddot{\mathrm{N}}:$

(d)

50. The Lewis structure of nitric acid, $HONO_2$, is a resonance hybrid. How important do you think the contribution of the following structure is to the resonance hybrid? Explain.



51. Draw Lewis structures for the following species, indicating formal charges and resonance where applicable:
(a) HCO_2^-
(b) HCO_3^-
(c) FSO_3^-
(d) $N_2O_3^{2-}$ (the nitrogen atoms are joined centrally with one oxygen atom on one N and two on the other)

52. Draw Lewis structures for the following species, indicating formal charges and resonance where applicable:
(a) $HOSO_3^-$
(b) H_2NCN
(c) FCO_2^-
(d) S_2N_2 (a cyclic structure with S and N alternating)

Odd-Electron Species

53. Write plausible Lewis structures for the following odd-electron species: **(a)** CH_3; **(b)** ClO_2; **(c)** NO_3.

54. Write plausible Lewis structures for the following free radicals: **(a)** $\cdot C_2H_5$; **(b)** $HO_2\cdot$; **(c)** $ClO\cdot$.

55. Which of the following species would you expect to be diamagnetic and which paramagnetic: **(a)** OH^-; **(b)** OH; **(c)** NO_3; **(d)** SO_3; **(e)** SO_3^{2-}; **(f)** HO_2?

56. Write a plausible Lewis structure for NO_2, and indicate whether the molecule is diamagnetic or paramagnetic. Two NO_2 molecules can join together (*dimerize*) to form N_2O_4. Write a plausible Lewis structure for N_2O_4, and comment on the magnetic properties of the molecule.

Expanded Valence Shells

57. In which of the following species is it *necessary* to employ an expanded valence shell to represent the Lewis structure: PO_4^{3-}, PI_3, ICl_3, $OSCl_2$, SF_4, ClO_4^-? Explain your choices.

58. Describe the carbon-to-sulfur bond in H_2CSF_4. That is, is it most likely a single, double, or triple bond?

Molecular Shapes

59. Use VSEPR theory to predict the geometric shapes of the following molecules and ions: **(a)** N_2; **(b)** HCN; **(c)** NH_4^+; **(d)** NO_3^-; **(e)** NSF.

60. Use VSEPR theory to predict the geometric shapes of the following molecules and ions: **(a)** PCl_3; **(b)** SO_4^{2-}; **(c)** $SOCl_2$; **(d)** SO_3; **(e)** BrF_4^+.

61. Each of the following is either linear, angular (bent), planar, tetrahedral, or octahedral. Indicate the correct shape of **(a)** H_2S; **(b)** N_2O_4; **(c)** HCN; **(d)** $SbCl_6^-$; **(e)** BF_4^-.

62. Predict the geometric shapes of **(a)** CO; **(b)** $SiCl_4$; **(c)** PH_3; **(d)** ICl_3; **(e)** $SbCl_5$; **(f)** SO_2; **(g)** AlF_6^{3-}.

63. One of the following ions has a *trigonal-planar* shape: SO_3^{2-}; PO_4^{3-}; PF_6^-; CO_3^{2-}. Which ion is it? Explain.

64. Two of the following have the same shape. Which two, and what is their shape? What are the shapes of the other two? NI_3, HCN, SO_3^{2-}, NO_3^-.

65. Each of the following molecules contains one or more multiple covalent bonds. Draw plausible Lewis structures to represent this fact, and predict the shape of each molecule. **(a)** CO_2; **(b)** Cl_2CO; **(c)** $ClNO_2$.

66. Sketch the probable geometric shape of a molecule of **(a)** N_2O_4 (O_2NNO_2); **(b)** C_2N_2 (NCCN); **(c)** C_2H_6 (H_3CCH_3); **(d)** C_2H_6O (H_3COCH_3).

67. Use the VSEPR theory to predict the shapes of the anions **(a)** ClO_4^-; **(b)** $S_2O_3^{2-}$ (that is, SSO_3^{2-}); **(c)** PF_6^-; **(d)** I_3^-.

68. Use the VSEPR theory to predict the shape of **(a)** the molecule OSF_2; **(b)** the molecule O_2SF_2; **(c)** the ion SF_5^-; **(d)** the ion ClO_4^-; **(e)** the ion ClO_3^-.

69. The molecular shape of BF_3 is planar (see Table 10.1). If a fluoride ion is attached to the B atom of BF_3 through a coordinate covalent bond, the ion BF_4^- results. What is the shape of this ion?

70. Explain why it is not necessary to find the Lewis structure with the smallest formal charges to make a successful prediction of molecular geometry in the VSEPR theory. For example, write Lewis structures for SO_2 having different formal charges, and predict the molecular geometry based on these structures.

71. Comment on the similarities and differences in the molecular structure of the following triatomic species: CO_2, NO_2^-, O_3, and ClO_2^-.

72. Comment on the similarities and differences in the molecular structure of the following four-atom species: NO_3^-, CO_3^{2-}, SO_3^{2-}, and ClO_3^-.

73. Draw a plausible Lewis structure for the following series of molecules and ions: **(a)** ClF_2^-; **(b)** ClF_3; **(c)** ClF_4^-; **(d)** ClF_5. Describe the electron group geometry and molecular structure of these species.

74. Draw a plausible Lewis structure for the following series of molecules and ions: **(a)** SiF_6^{2-}; **(b)** PF_5; **(c)** SF_4; **(d)** XeF_4. Describe the electron group geometry and molecular structure of these species.

Shapes of Molecules with More Than One Central Atom

75. Sketch the propyne molecule, $CH_3C{\equiv}CH$. Indicate the bond angles in this molecule. What is the maximum number of atoms that can be in the same plane?

76. Sketch the propene molecule, $CH_3CH{=}CH_2$. Indicate the bond angles in this molecule. What is the maximum number of atoms that can be in the same plane?

77. Lactic acid has the formula $CH_3CH(OH)COOH$. Sketch the lactic acid molecule, and indicate the various bond angles.

78. Levulinic acid has the formula $CH_3(CO)CH_2CH_2COOH$. Sketch the levulinic acid molecule, and indicate the various bond angles.

79. Sketch, by using the dash and wedge symbolism, the H_2NCH_2CHO molecule, and indicate the various bond angles.

80. One of the isomers of chloromethanol has the formula $ClCH_2OH$. Sketch, by using the dash and wedge symbolism, this isomer of chloromethanol, and indicate the various bond angles.

Polar Molecules

81. Predict the shapes of the following molecules, and then predict which would have resultant dipole moments: **(a)** SO_2; **(b)** NH_3; **(c)** H_2S; **(d)** C_2H_4; **(e)** SF_6; **(f)** CH_2Cl_2.

82. Which of the following molecules would you expect to be polar: **(a)** HCN; **(b)** SO_3; **(c)** CS_2; **(d)** OCS; **(e)** $SOCl_2$; **(f)** SiF_4; **(g)** POF_3? Give reasons for your conclusions.

83. The molecule H_2O_2 has a resultant dipole moment of 2.2 D. Can this molecule be linear? If not, describe a shape that might account for this dipole moment.

84. Refer to the Integrative Example. A compound related to nitryl fluoride is nitrosyl fluoride, FNO. For this molecule, indicate **(a)** a plausible Lewis structure and **(b)** the geometric shape. **(c)** Explain why the measured resultant dipole moment for FNO is larger than the value for FNO_2.

Bond Lengths

85. *Without* referring to tables in the text, indicate which of the following bonds you would expect to have the greatest bond length, and give your reasons. **(a)** O_2; **(b)** N_2; **(c)** Br_2; **(d)** BrCl.

86. Estimate the lengths of the following bonds and indicate whether your estimate is likely to be too high or too low: **(a)** I—Cl; **(b)** C—F.

87. A relationship between bond lengths and single covalent radii of atoms is given on page 443. Use this relationship together with appropriate data from Table 10.2 to estimate these single-bond lengths. **(a)** I—Cl; **(b)** O—Cl; **(c)** C—F; **(d)** C—Br.

88. In which of the following molecules would you expect the oxygen-to-oxygen bond to be the *shortest*: **(a)** H_2O_2, **(b)** O_2, **(c)** O_3? Explain.

89. Refer to the Integrative Example. Use data from the chapter to estimate the length of the N—F bond in FNO_2.

90. Write a Lewis structure of the hydroxylamine molecule, H_2NOH. Then, with data from Table 10.2, determine all the bond lengths.

Bond Energies

91. A reaction involved in the formation of ozone in the upper atmosphere is $O_2 \longrightarrow 2\,O$. *Without* referring to Table 10.3, indicate whether this reaction is endothermic or exothermic. Explain.

92. Use data from Table 10.3, but *without performing detailed calculations*, determine whether each of the following reactions is exothermic or endothermic.

(a) $CH_4(g) + I(g) \longrightarrow \cdot CH_3(g) + HI(g)$

(b) $H_2(g) + I_2(g) \longrightarrow 2\,HI(g)$

93. Use data from Table 10.3 to estimate the enthalpy change (ΔH) for the following reaction.

$$C_2H_6(g) + Cl_2(g) \longrightarrow C_2H_5Cl(g) + HCl(g) \qquad \Delta H = ?$$

94. One of the chemical reactions that occurs in the formation of photochemical smog is $O_3 + NO \longrightarrow NO_2 + O_2$. Estimate the enthalpy change of this reaction by using appropriate Lewis structures and data from Table 10.3.

95. Estimate the standard enthalpies of formation at 25 °C and 1 bar of **(a)** OH(g); **(b)** $N_2H_4(g)$. Write Lewis structures and use data from Table 10.3, as necessary.

96. Use ΔH for the reaction in Example 10-15 and other data from Appendix D to estimate $\Delta H_f^\circ[CH_3Cl(g)]$.

97. Use bond energies from Table 10.3 to estimate the enthalpy change (ΔH) for the following reaction.

$$C_2H_2(g) + H_2(g) \longrightarrow C_2H_4(g) \qquad \Delta H = ?$$

98. Equations (1) and (2) can be combined to yield the equation for the formation of $CH_4(g)$ from its elements.

$$\begin{array}{llll}
(1) & C(s) & \longrightarrow C(g) & \Delta H = 717\text{ kJ} \\
(2) & C(g) + 2\,H_2(g) & \longrightarrow CH_4(g) & \Delta H = ? \\
\hline
\textit{Overall:} & C(s) + 2\,H_2(g) & \longrightarrow CH_4(g) & \Delta H_f^\circ = -75\text{ kJ/mol}
\end{array}$$

Use the preceding data and a bond energy of 436 kJ/mol for H_2 to estimate the C—H bond energy. Compare your result with the value listed in Table 10.3.

99. One reaction involved in the sequence of reactions leading to the destruction of ozone is

$$NO_2(g) + O(g) \longrightarrow NO(g) + O_2(g)$$

Calculate ΔH° for this reaction by using the thermodynamic data in Appendix D. Use your ΔH° value, plus data from Table 10.3, to estimate the nitrogen–oxygen bond energy in NO_2. [*Hint:* The structure of nitrogen dioxide, NO_2, is best represented as a resonance hybrid of two equivalent Lewis structures.]

100. A reaction involved in the sequence of reactions leading to the destruction of ozone is

$$O_3(g) + O(g) \longrightarrow 2\,O_2(g) \qquad \Delta H^\circ = -394\text{ kJ}$$

Estimate the oxygen-oxygen bond energy in ozone by using the oxygen–oxygen bond energy in dioxygen from Table 10.3. Compare this value with the O—O and O═O bond energies in Table 10.3. How could you explain any differences?

Integrative and Advanced Exercises

101. Given the bond-dissociation energies: nitrogen-to-oxygen bond in NO, 631 kJ/mol; H—H in H_2, 436 kJ/mol; N—H in NH_3, 389 kJ/mol; O—H in H_2O, 463 kJ/mol; calculate ΔH for the reaction.

$$2\,NO(g) + 5\,H_2(g) \longrightarrow 2\,NH_3(g) + 2\,H_2O(g)$$

102. The following statements are not made as carefully as they might be. Criticize each one.
(a) Lewis structures with formal charges are incorrect.
(b) Triatomic molecules have a planar shape.
(c) Molecules in which there is an electronegativity difference between the bonded atoms are polar.

103. A compound consists of 47.5% S and 52.5% Cl, by mass. Write a Lewis structure based on the empirical formula of this compound, and comment on its deficiencies. Write a more plausible structure with the *same* ratio of S to Cl.

104. A 0.325 g sample of a gaseous hydrocarbon occupies a volume of 193 mL at 749 mmHg and 26.1 °C. Determine the molecular mass, and write a plausible condensed structural formula for this hydrocarbon.

105. A 1.24 g sample of a hydrocarbon, when completely burned in an excess of $O_2(g)$, yields 4.04 g CO_2 and 1.24 g H_2O. Draw a plausible structural formula for the hydrocarbon molecule. [*Hint:* There is more than one possible arrangement of the C and H atoms.]

106. Draw Lewis structures for two different molecules with the formula C_3H_4. Is either of these molecules linear? Explain.

107. Sodium azide, NaN_3, is the nitrogen gas-forming substance used in automobile air-bag systems. It is an ionic compound containing the azide ion, N_3^-. In this ion, the two nitrogen-to-nitrogen bond lengths are 116 pm. Describe the resonance hybrid Lewis structure of this ion.

108. Use the bond-dissociation energies of $N_2(g)$ and $O_2(g)$ in Table 10.3, together with data from Appendix D, to estimate the bond-dissociation energy of NO(g).

109. Hydrogen azide, HN_3, is a liquid that explodes violently when subjected to physical shock. In the HN_3 molecule, one nitrogen-to-nitrogen bond length is 113 pm, and the other is 124 pm. The H—N—N bond angle is 112°. Draw Lewis structures and a sketch of the molecule consistent with these facts.

110. A few years ago the synthesis of a salt containing the N_5^+ ion was reported. What is the likely shape of this ion—linear, bent, zigzag, tetrahedral, seesaw, or square-planar? Explain your choice.

111. Carbon suboxide has the formula C_3O_2. The carbon-to-carbon bond lengths are 130 pm and carbon-to-oxygen, 120 pm. Propose a plausible Lewis structure to account for these bond lengths, and predict the shape of the molecule.

112. In certain polar solvents, PCl_5 undergoes an ionization reaction in which a Cl^- ion leaves one PCl_5 molecule and attaches itself to another. The products of the ionization are PCl_4^+ and PCl_6^-. Draw a sketch showing the changes in geometric shapes that occur in this ionization (that is, give the shapes of PCl_5, PCl_4^+, and PCl_6^-).

$$2\,PCl_5 \rightleftharpoons PCl_4^+ + PCl_6^-$$

113. Estimate the enthalpy of formation of HCN using bond energies from Table 10.3, data from elsewhere in the text, and the reaction scheme outlined as follows.

$$\begin{array}{llll}
(1) & C(s) & \rightarrow C(g) & \Delta H^\circ = ? \\
(2) & C(g) + \tfrac{1}{2}N_2(g) + \tfrac{1}{2}H_2(g) & \rightarrow HCN(g) & \Delta H^\circ = ? \\
\hline
\textit{Overall:} & C(g) + \tfrac{1}{2}N_2(g) + \tfrac{1}{2}H_2(g) & \rightarrow HCN(g) & \Delta H_f^\circ = ?
\end{array}$$

114. The enthalpy of formation of $H_2O_2(g)$ is −136 kJ/mol. Use this value, with other appropriate data from the text, to estimate the oxygen-to-oxygen single-bond energy. Compare your result with the value listed in Table 10.3.

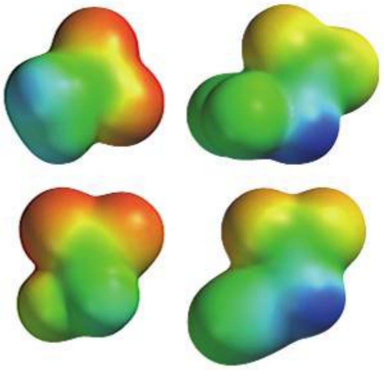
115. Use the VSEPR theory to predict a probable shape of the molecule F_4SCH_2, and explain the source of any ambiguities in your prediction.

116. The enthalpy of formation of methanethiol, $CH_3SH(g)$, is −22.9 kJ/mol. Methanethiol can be synthesized by the reaction of gaseous methanol and $H_2S(g)$. Water vapor is another product. Use this information and data from elsewhere in the text to estimate the carbon-to-sulfur bond energy in methanethiol.

117. For LiBr, the dipole moment (measured in the gas phase) and the bond length (measured in the solid state) are 7.268 D and 217 pm, respectively. For NaCl, the corresponding values are 9.001 D and 236.1 pm. **(a)** Calculate the percent ionic character for each bond. **(b)** Compare these values with the expected ionic character based on differences in electronegativity (see Figure 10-7). **(c)** Account for any differences in the values obtained in these two different ways.

118. One possibility for the electron-group geometry for *seven* electron groups is pentagonal-bipyramidal, as found in the IF_7 molecule. Write the VSEPR notation for this molecule. Sketch the structure of the molecule, labeling all the bond angles.

119. The extent to which an acid (HA) dissociates in water depends upon the stability of the anion (A^-); the more stable the anion, the more extensive is the dissociation of the acid. The anion is most stable when the negative charge is distributed over the whole anion rather than localized at one particular atom. Consider the following acids: acetic acid, fluoroacetic acid, cyanoacetic acid, and nitroacetic acid. Draw Lewis structures for their anions, including contributing resonance structures. Rank the acids in order of increasing extent of dissociation. Electrostatic potential maps for the four anions are provided on the next page. Identify which map corresponds to which anion, and discuss whether the maps confirm conclusions based on Lewis structures.



120. R. S. Mulliken proposed that the electronegativity (χ) of an atom is given by

$$\chi = k \times (I - EA)$$

where I and EA are the ionization energy and electron affinity of the atom, respectively. Using the electron affinities and ionization energy values for the halogen atoms up to iodine, estimate the value of k by employing the electronegativity values in Figure 10-6. Estimate the electron affinity of At.

121. When molten sulfur reacts with chlorine gas, a vile-smelling orange liquid forms. When analyzed, the liquid compound has the empirical formula SCl. Several possible Lewis structures are shown below. Criticize these structures and choose the best one.

(a)

$\mathrm{:\ddot{C}l-\ddot{S}=\ddot{S}-\ddot{C}l:}$

(b)

$\mathrm{:\ddot{C}l=\ddot{S}-\ddot{S}=\ddot{C}l:}$

(c)

$\mathrm{:\ddot{S}=\ddot{C}l-\ddot{C}l=\ddot{S}:}$

(d)

$\mathrm{:\ddot{C}l-\ddot{S}\equiv S-\ddot{C}l:}$

(e)

$\mathrm{:\ddot{C}l-\ddot{S}-\ddot{S}-\ddot{C}l:}$

122. Hydrogen azide, HN_3, can exist in two forms. One form has the three nitrogen atoms connected in a line; and the nitrogen atoms form a triangle in the other. Construct Lewis structures for these isomers and describe their shapes. Other interesting derivatives are nitrosyl azide (N_4O) and trifluoromethyl azide (CF_3N_3). Describe the shapes of these molecules based on a line of nitrogen atoms.

123. A pair of isoelectronic species for C and N exist with the formula X_2O_4 in which there is an $X-X$ bond. A corresponding fluoride of boron also exists. Draw Lewis structures for these species and describe their shapes.

124. Acetone $(CH_3)C{=}O$, a ketone, will react with a strong base (A^-) to produce the enolate anion, $CH_3(C{=}O)CH_2^-$. Draw the Lewis structure of the enolate anion, and describe the relative contributions of any resonance structures.

125. The species PBr_4^- has been synthesized and has been described as a tetrahedral anion. Comment on this description.

126. One of the allotropes of sulfur is a ring of eight sulfur atoms. Draw the Lewis structure for the S_8 ring. Is the ring likely to be planar? The S_8 ring can be oxidized to produce S_8O. In S_8O, the oxygen atom is bonded to one of the S atoms and the S_8 ring is still intact. Draw the Lewis structure for S_8O.

127. One of the allotropes of phosphorus consists of four phosphorus atoms at the corners of a tetrahedron. Draw a Lewis structure for this allotrope that satisfies the octet rule. The P_4 molecule can be oxidized to P_4O_6, where the oxygen atoms insert between the phosphorus atoms. Draw the Lewis structure of this oxide. Are the $P-O-P$ bonds linear?

Feature Problems

128. Pauling's reasoning in establishing his original electronegativity scale went something like this: If we assume that the bond $A-B$ is nonpolar, its bond energy is the average of the bond energies of $A-A$ and $B-B$. The *difference* between the calculated and measured bond energies of the bond $A-B$ is attributable to the partial ionic character of the bond and is called the *ionic resonance energy* (IRE). If the IRE is expressed in kilojoules per mole, the relationship between IRE and the electronegativity difference is $(\Delta EN)^2 = IRE/96$. To test this basis for an electronegativity scale,

(a) Use data from Table 10.3 to determine IRE for the $H-Cl$ bond.

(b) Determine ΔEN for the $H-Cl$ bond.

(c) Establish the approximate percent ionic character in the $H-Cl$ bond by using the result of part (b) and Figure 10-7. Compare this result with that obtained in Example 10-4.

129. On page 431, the bond angle in the H_2O molecule is given as 104° and the resultant dipole moment as $\mu = 1.84\,D$.

(a) By an appropriate geometric calculation, determine the value of the $H-O$ bond dipole in H_2O.

(b) Use the same method as in part (a) to estimate the bond angle in H_2S, given that the $H-S$ bond dipole is 0.67 D and that the resultant dipole moment is $\mu = 0.93\,D$.

(c) Refer to Figure 10-15. Given the bond dipoles 1.87 D for the $C-Cl$ bond and 0.30 D for the

C—H bond, together with $\mu = 1.04\,\text{D}$, estimate the H—C—Cl bond angle in $CHCl_3$.

130. Alternative strategies to the one used in this chapter have been proposed for applying the VSEPR theory to molecules or ions with a single central atom. In general, these strategies do not require writing Lewis structures. In one strategy, we write

(1) the total number of electron pairs = [(number of valence electrons) ± (electrons required for ionic charge)]/2
(2) the number of bonding electron pairs = (number of atoms) − 1
(3) the number of electron pairs around central atom = total number of electron pairs − 3 × [number of terminal atoms (excluding H)]
(4) the number of lone-pair electrons = number of central atom pairs − number of bonding pairs

After evaluating items 2, 3, and 4, establish the VSEPR notation and determine the molecular shape. Use this method to predict the geometrical shapes of the following: **(a)** PCl_5; **(b)** NH_3; **(c)** ClF_3; **(d)** SO_2; **(e)** ClF_4^-; **(f)** PCl_4^+. Justify each of the steps in the strategy, and explain why it yields the same results as the VSEPR method based on Lewis structures. How does the strategy deal with multiple bonds?

Self-Assessment Exercises

131. In your own words, define the following terms: **(a)** valence electrons; **(b)** electronegativity; **(c)** bond-dissociation energy; **(d)** double covalent bond; **(e)** coordinate covalent bond.

132. Briefly describe each of the following ideas: **(a)** formal charge; **(b)** resonance; **(c)** expanded valence shell; **(d)** bond energy.

133. Explain the important distinctions between **(a)** ionic and covalent bonds; **(b)** lone-pair and bond-pair electrons; **(c)** molecular geometry and electron-group geometry; **(d)** bond dipole and resultant dipole moment; **(e)** polar molecule and nonpolar molecule.

134. Of the following species, the one with a triple covalent bond is **(a)** NO_3^-; **(b)** CN^-; **(c)** CO_2; **(d)** $AlCl_3$.

135. The formal charges on the O atoms in the ion $[ONO]^+$ is **(a)** −2; **(b)** −1; **(c)** 0; **(d)** +1.

136. Which molecule is nonlinear? **(a)** SO_2; **(b)** CO_2; **(c)** HCN; **(d)** NO.

137. Which molecule is nonpolar? **(a)** SO_3; **(b)** CH_2Cl_2; **(c)** NH_3; **(d)** FNO.

138. The highest bond-dissociation energy is found in **(a)** O_2; **(b)** N_2; **(c)** Cl_2; **(d)** I_2.

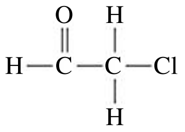
139. The greatest bond length is found in **(a)** O_2; **(b)** N_2; **(c)** Br_2; **(d)** BrCl.

140. Draw plausible Lewis structures for the following species; use expanded valence shells where necessary. **(a)** Cl_2O; **(b)** PF_3; **(c)** CO_3^{2-}; **(d)** BrF_5.

141. Predict the shapes of the following sulfur-containing species. **(a)** SO_2; **(b)** SO_3^{2-}; **(c)** SO_4^{2-}.

142. Without referring to tables or figures in the text other than the periodic table, indicate which of the following atoms, Bi, S, Ba, As, or Mg, has the intermediate value when they are arranged in order of increasing electronegativity.

143. Use data from Tables 10.2 and 10.3 to determine for each bond in this following structure **(a)** the bond length and **(b)** the bond energy.



$$\mathrm{H{-}\overset{\overset{\displaystyle O}{\|}}{C}{-}\underset{\underset{\displaystyle H}{|}}{\overset{\overset{\displaystyle H}{|}}{C}}{-}Cl}$$

144. What is the VSEPR theory? On what physical basis is the VSEPR theory founded?

145. Use the NH_3 molecule as an example to explain the difference between molecular geometry and electron-group geometry.

146. If you have four electron pairs around a central atom, under what circumstances can you have a pyramidal molecule? Similarly, how can you have a bent molecule? What are the expected bond angles in each case?

147. Draw three resonance structures for the sulfine molecule, H_2CSO. Do not consider ring structures.

148. Construct a concept map illustrating the connections between Lewis dot structures, the shapes of molecules, and polarity.

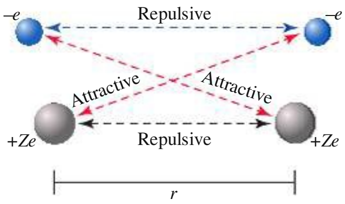
11-8 Some Unresolved Issues: Can Electron Charge-Density Plots Help?

Although the Lewis theory has been useful in our discussion of chemical bonding, it does have shortcomings. For example, it does not help explain why metals conduct electricity or how a semiconductor works. Although we will continue to use the Lewis theory for most purposes, some cases require more sophisticated approaches. One such approach involves the familiar *s*, *p*, and *d* atomic orbitals, or mixed-orbital types called *hybrid orbitals*. A second approach involves the creation of a set of orbitals that belongs to a molecule as a whole. Electrons are then assigned to these *molecular orbitals*.

Our purpose in this chapter is not to try to master theories of covalent bonding in all their details. We want simply to discover how these theories provide models that yield deeper insights into the nature of chemical bonding than do Lewis structures alone.



▲ FIGURE 11-1
Type of interactions between two hydrogen atoms
The types of interactions that occur as two hydrogen atoms, infinitely separated, approach each other. The dashed lines represent the types of interactions (red for attractive interactions and blue and black for repulsive interactions). The solid black line represents the internuclear distance, *r*, between the two hydrogen atoms.

11-1 What a Bonding Theory Should Do

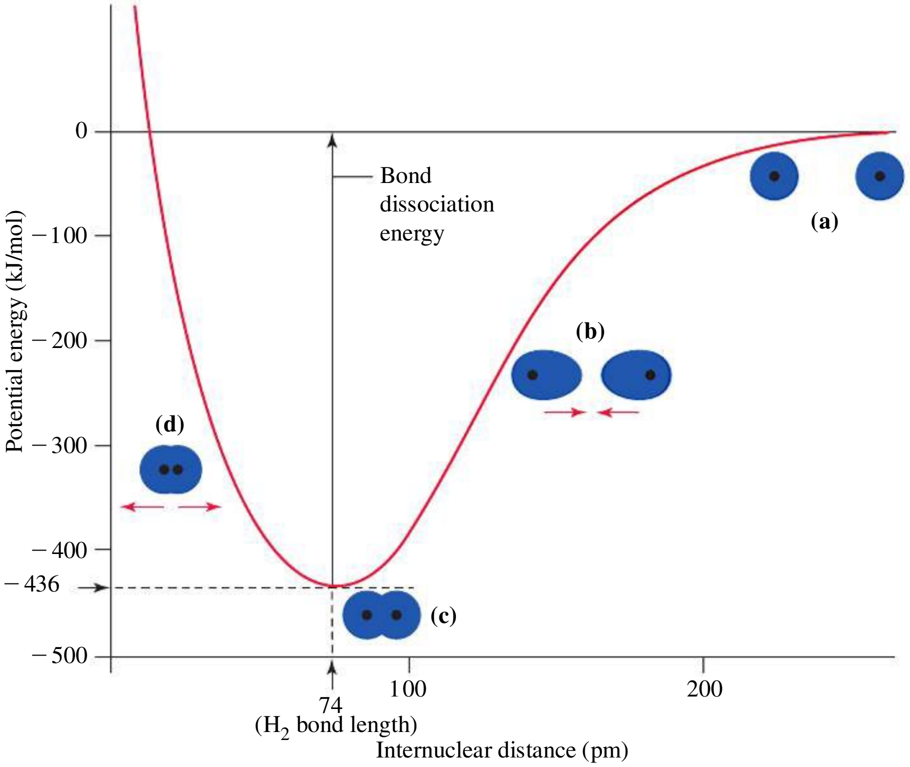
The hydrogen molecule is a simple model for discussing bonding theories. Imagine bringing together two H atoms that are initially very far apart. When the H atoms are infinitely far apart, the two H atoms do not interact with each other, and by convention the net energy of interaction between the H atoms is zero. As the two H atoms approach each other, three types of interactions occur: (1) each electron is attracted to the other nucleus (illustrated by a red dashed line in Fig. 11-1); (2) the electrons repel each other (illustrated by a blue dashed line in Fig. 11-1); and (3) the two nuclei repel each other (illustrated by a black dashed line in Fig. 11-1).

We can plot potential energy—the net energy of interaction of the atoms—as a function of the distance between the atomic nuclei.

Figure 11-2 shows the net energy of interaction of two H atoms. This starts at zero when the atoms are very far apart (condition a). At intermediate distances (condition b), attractive forces predominate and the potential energy is negative. At very small internuclear distances (condition d), repulsive forces exceed attractive forces and the potential energy is positive. At one particular internuclear distance (74 pm, condition c) the potential energy reaches its lowest value (−436 kJ/mol). This is the condition in which the two H atoms combine into a H_2 molecule through a covalent bond. The nuclei continuously move back and forth; that is, the molecule vibrates, but the average internuclear distance remains constant. This internuclear distance corresponds to the *bond length*. The potential energy corresponds to the negative of the *bond-dissociation energy*. A theory of covalent bonding should help us understand why a given molecule has its particular set of observed properties—bond-dissociation energies, bond lengths, bond angles, and so on.

There are several approaches to understanding bonding. The approach used depends on the situation because different methods have different strengths and weaknesses. The strength of the Lewis theory is in the ease with which it can be applied; a Lewis structure can be written rather quickly. VSEPR theory makes it possible to propose molecular shapes that are generally in good agreement with

▶ FIGURE 11-2
Energy of interaction of two hydrogen atoms plotted for internuclear separations from zero to infinity
(a) The potential energy is defined as zero when the two H atoms are infinitely separated. **(b)** Where the curve slopes downward from right to left, the net interaction is attractive. When the interaction is attractive, the potential energy decreases as the internuclear distance, *r*, decreases. **(c)** Where the curve is flat, at the bottom of the potential energy well, there is no tendency either to attract or to repel. The molecule is most stable at this internuclear distance (74 pm). **(d)** Where the curve slopes upward from right to left, the interaction is repulsive. When the interaction is repulsive, the potential energy increases as the internuclear distance, *r*, decreases.



experimental results. However, neither method yields quantitative information about bond energies and bond lengths, and the Lewis theory has problems with odd-electron species and situations in which it is not possible to represent a molecule through a single structure (resonance).

11-2 Introduction to the Valence-Bond Method

Recall the region of high electron probability in a H atom that we described in Chapter 8 through the mathematical function called a 1*s* orbital (page 328). As the two H atoms pictured in Figure 11-2 approach each other, these regions begin to interpenetrate. We say that the two orbitals overlap. Furthermore, we can say that a bond is produced between the two atoms because of the high electron density probability found in the region between the atomic nuclei where the 1*s* orbitals overlap. The increased electron density, with its negative charge, attracts the two positively charged nuclei. In this way, a covalent bond is formed between the two H atoms in the H_2 molecule.

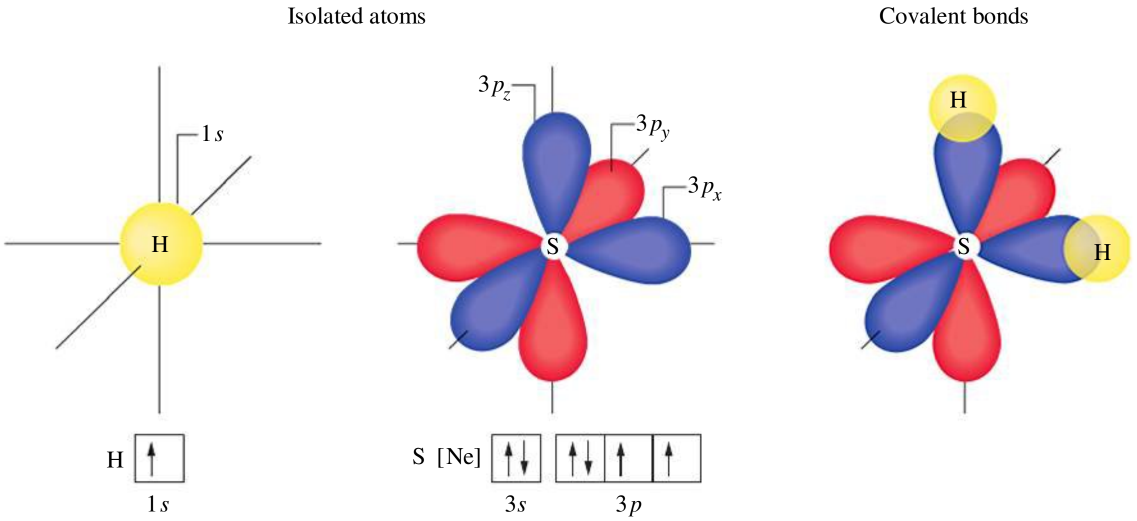
A description of covalent bond formation in terms of atomic orbital overlap is called the **valence-bond method**. The creation of a covalent bond in the valence-bond method is normally based on the overlap of half-filled orbitals, but sometimes such an overlap involves a filled orbital on one atom and an empty orbital on another. The valence-bond method gives a *localized* electron model of bonding: Core electrons and lone-pair valence electrons retain the same orbital locations as in the separated atoms, and the charge density of the bonding electrons is concentrated in the region of orbital overlap.

Figure 11-3 shows the imagined overlap of atomic orbitals in the formation of hydrogen-to-sulfur bonds in hydrogen sulfide. Note especially that maximum overlap between the 1*s* orbital of a H atom and a 3*p* orbital of a S atom occurs along a line joining the centers of the H and S atoms. The two half-filled sulfur

◀ What we are calling "overlap" is actually an interpenetration of two orbitals.

KEEP IN MIND

the actual orbital shapes are pointed out on page 331. The orbitals here, as well as those throughout the rest of the book, are schematic representations.



▲ FIGURE 11-3
Bonding in H_2S represented by atomic orbital overlap
For S, only 3*p* orbitals are shown. The phases of the lobes of the sulfur 3*p* orbitals are shown in red and blue for positive and negative. However, we do not know which lobe is positive or negative; all we know is that they are opposite. Although the angular part of the *p* orbital is circular, when multiplied by the radial part of the wave function, each lobe is more pear shaped, similar to the probability distribution shown in Figure 8-27(c). Bond formation occurs between orbitals that are in phase (same color), although the hydrogen 1*s* orbital is colored yellow for clarity.

$3p$ orbitals that overlap in H_2S are perpendicular to each other, and the valence-bond method suggests a H—S—H bond angle of 90°. This is in good agreement with the observed angle of 92°.

11-1 ARE YOU WONDERING...

Why the overlap of orbitals leads to a chemical bond?

The origin of this extra stability comes from the overlap of the two orbitals in which the two atomic wave functions are *in phase*, leading to constructive interference of the wave functions between the two nuclei and hence increased electron density between the two nuclei. The increased electron density, with its negative charge, attracts the two positively charged nuclei, leading to an energy that is lower than that of the two separated atoms. Thus, the increased electron charge density between the nuclei produces the chemical bond. We will say more about the interaction between orbitals later in this chapter.

EXAMPLE 11-1 Using the Valence-Bond Method to Describe a Molecular Structure

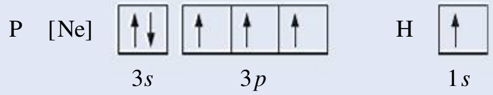
Describe the phosphine molecule, PH_3. by the valence-bond method.

Analyze

We use four steps when applying the valence-bond method. First, we identify the valence orbitals of the central atom. Second, we sketch the valence orbitals. Third, we bring in the atoms to be bonded to the central atom and sketch the orbital overlap. Finally, we describe the resulting structure. These steps are illustrated in Figure 11-4.

Solve

Step 1. Draw valence-shell orbital diagrams for the separate atoms.



Step 2. Sketch the orbitals of the central atom (P) that are involved in the overlap. These are the half-filled $3p$ orbitals (Fig. 11-4).

Step 3. Complete the structure by bringing together the bonded atoms and representing the orbital overlap.

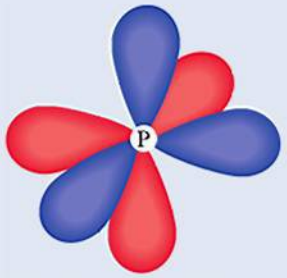
Step 4. Describe the structure. PH_3 is a *trigonal-pyramidal* molecule. The three H atoms lie in the same plane. The P atom is situated at the top of the pyramid above the plane of the H atoms, and the three H—P—H bond angles are 90°.

Assess

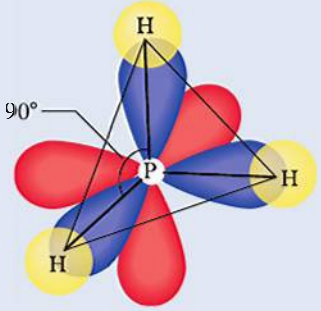
The predicted H—P—H bond angle is 90°, and the experimentally measured bond angles are 93° to 94°. These are in good agreement.

PRACTICE EXAMPLE A: Use the valence-bond method to describe bonding and the expected molecular geometry in nitrogen triiodide, NI_3.

PRACTICE EXAMPLE B: Describe the molecular geometry of NH_3, first using the VSEPR method and then using the valence-bond method described above. How do your answers differ? Which method seems to be more appropriate in this case? Explain.



Bonding orbitals of P atom



Covalent bonds formed

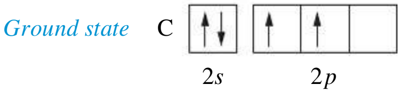
Bonding and structure of the PH_3 molecule—Example 11-1 illustrated
Only bonding orbitals are shown. The $1s$ orbitals (yellow) of three H atoms overlap with the three $3p$ orbitals of the P atom.

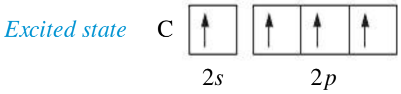
11-3 Hybridization of Atomic Orbitals

If we try to extend the unmodified valence-bond method of Section 11-2 to a greater number of molecules, we are quickly disappointed. In most cases, our descriptions of molecular geometry based on the simple overlap of unmodified atomic orbitals do not conform to observed measurements. For example, based on the *ground-state* electron configuration of the valence shell of carbon

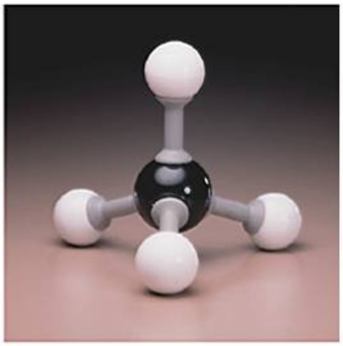


and employing only half-filled orbitals, we expect the existence of a molecule with the formula CH_2 and a bond angle of 90°. The CH_2 molecule is a highly reactive molecule observed only under specially designed circumstances.

The simplest hydrocarbon observed under normal laboratory conditions is methane, CH_4. This is a stable, unreactive molecule with a molecular formula consistent with the octet rule of the Lewis theory. To obtain this molecular formula by the valence-bond method, we need an orbital diagram for carbon in which there are four unpaired electrons so that orbital overlap leads to four C—H bonds. To get such a diagram, imagine that one of the 2*s* electrons in a ground-state C atom absorbs energy and is promoted to the empty 2*p* orbital. The resulting electron configuration is that of an *excited state*.



The electron configuration of this excited state suggests a molecule with three mutually perpendicular C—H bonds based on the 2*p* orbitals of the C atom (90° bond angles). The fourth bond would be directed to whatever position in the molecule could accommodate the fourth H atom. This description, however, does not agree with the experimentally determined H—C—H bond angles, all four of which are found to be 109.5°, the same as predicted by VSEPR theory (Fig. 11-5). A bonding scheme based on the excited-state electron configuration does a poor job of explaining the bond angles in CH_4.



▲ FIGURE 11-5
Ball-and-stick model of methane, CH_4
The molecule has a tetrahedral structure, and the H—C—H bond angles are 109.5°.

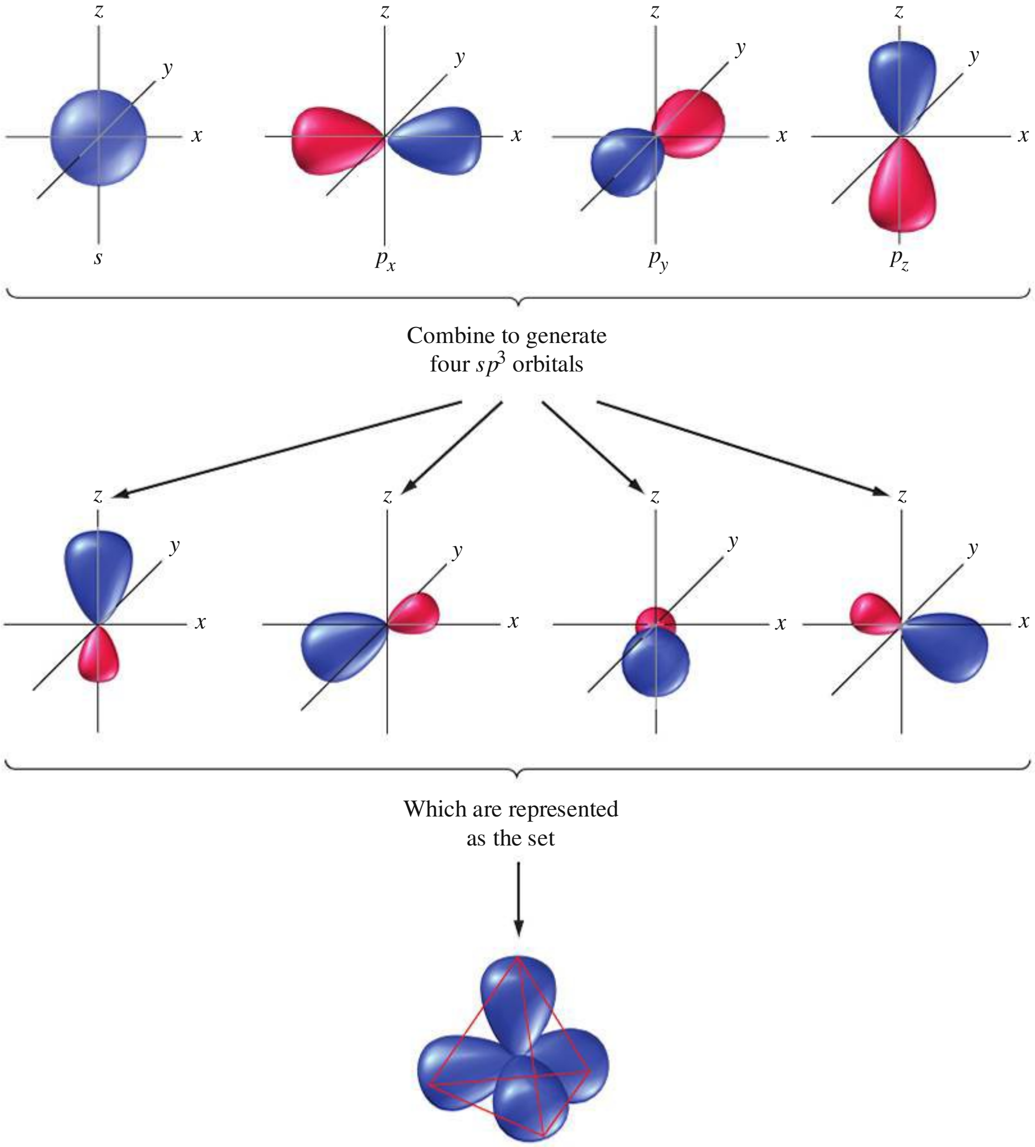
The problem is not with the theory but with the way the situation has been defined. We have been describing *bonded* atoms as though they have the same kinds of orbitals (that is, *s*, *p*, and so on) as isolated, *nonbonded* atoms. This assumption worked rather well for H_2S and PH_3, but we have no reason to expect these unmodified pure atomic orbitals to work equally well in all cases.

One way to deal with this problem is to modify the atomic orbitals of the bonded atoms. Recall that atomic orbitals are mathematical expressions of the electron waves in an atom. An algebraic combination of the wave equations of the 2*s* and three 2*p* orbitals of the carbon atom produces a new set of four identical orbitals. These new orbitals, which are directed in a tetrahedral fashion, have energies that are intermediate between those of the 2*s* and 2*p* orbitals. This mathematical process of replacing pure atomic orbitals with reformulated atomic orbitals for bonded atoms is called **hybridization**, and the new orbitals are called **hybrid orbitals**. Figure 11-6 pictures the hybridization of one *s* and three *p* orbitals into a new set of four sp^3 **hybrid orbitals**. Each sp^3 hybrid orbital has 25% *s* character and 75% *p* character.

◀ The algebraic combination of wave functions is, in fact, a linear combination of atomic orbitals; that is, they are simply added or subtracted. The resultant linear combinations are solutions to the Schrödinger equation of the molecule.

◀ **Hybridization** occurs only when the bonds are being formed.

In a hybridization scheme, *the number of hybrid orbitals equals the total number of atomic orbitals that are combined*. The symbols identify the numbers and kinds of orbitals involved. Thus, sp^3 signifies that *one s* and *three p* orbitals are



z

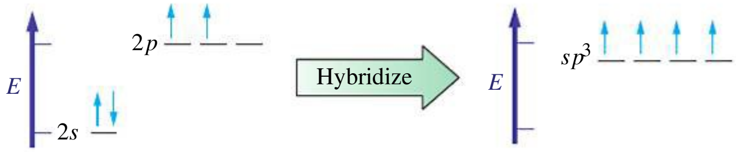
Which are represented as the set

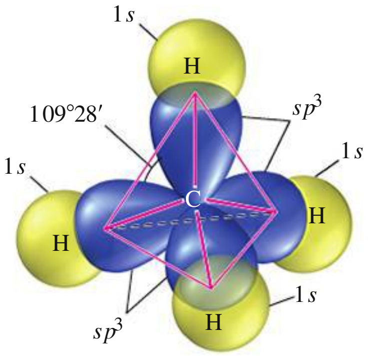
▲ FIGURE 11-6
The sp^3 hybridization scheme

combined. A useful representation of sp^3 hybridization of the valence-shell orbitals of carbon is



Note that the three p orbitals move down by $\frac{1}{4}$ of the energy difference between the s orbitals and the p orbitals and that the s orbital moves up by $\frac{3}{4}$ of that energy difference; that is, energy is conserved. Figure 11-7 shows sp^3 hybrid orbitals and bond formation in methane.

The objective of a hybridization scheme is an after-the-fact rationalization of the experimentally observed shape of a molecule. Hybridization is not an actual physical phenomenon. We cannot observe electron charge distributions changing from those of pure orbitals to those of hybrid orbitals. Moreover, for some covalent bonds no single hybridization scheme works well. Nevertheless,

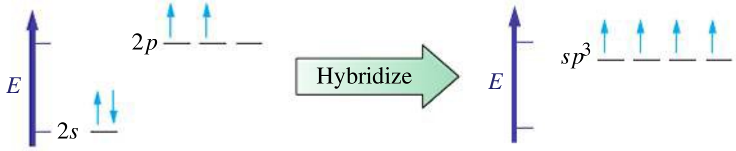


▲ FIGURE 11-7
Bonding and structure of CH_4
The four carbon orbitals are sp^3 hybrid orbitals (blue). Those of the hydrogen atoms (yellow) are 1s. The structure is tetrahedral, with H—C—H bond angles of 109.5° (more precisely, 109.471). Remember that the hydrogen orbitals and the carbon hybrid orbitals have the same phase, but we have colored the hydrogen orbitals yellow for clarity.

the concept of hybridization works very well for carbon-containing molecules and is therefore used a great deal in organic chemistry.

Bonding in H_2O and NH_3

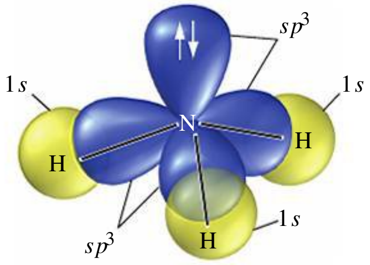
Applied to H_2O and NH_3, VSEPR theory describes a tetrahedral electron-group geometry for *four* electron groups. This, in turn, requires an sp^3 hybridization scheme for the central atoms in H_2O and NH_3. This scheme suggests angles of 109.5° for the H—O—H bond in water and the H—N—H bonds in NH_3. These angles are in reasonably good agreement with the experimentally observed bond angles of 104.5° in water and 107° in NH_3. Bonding in NH_3, for example, can be described in terms of the following valence-shell orbital diagram for nitrogen.



◀ Notice that hybrid orbitals can accommodate lone-pair electrons as well as bonding electrons.

Because one of the sp^3 orbitals is occupied by a lone pair of electrons, only the three half-filled sp^3 orbitals are involved in bond formation. This suggests the trigonal-pyramidal molecular geometry depicted in Figure 11-8, just as does VSEPR theory.

Even though the sp^3 hybridization scheme seems to work quite well for H_2O and NH_3, both theoretical and experimental (spectroscopic) evidence favors a description based on *unhybridized p* orbitals of the central atoms. The H—O—H and H—N—H bond angle expected for 1*s* and 2*p* atomic orbital overlaps is 90°, which does not conform to the observed bond angles. One possible explanation is that because O—H and N—H bonds have considerable ionic character, repulsions between the positive partial charges associated with the H atoms force the H—O—H and H—N—H bonds to "open up" to values greater than 90°. The issue of how best to describe the bonding orbitals in H_2O and NH_3 is still unsettled and underscores the occasional difficulty of finding a single theory that is consistent with all the available evidence.



▲ FIGURE 11-8
sp^3 hybrid orbitals and bonding in NH_3
An sp^3 hybridization scheme conforms to a molecular geometry in close agreement with experimental observations. Excluding the orbital occupied by a lone pair of electrons, the centers of the atoms form a trigonal pyramid. The hydrogen orbitals are colored yellow for clarity, but they have the same phase as the nitrogen hybrid orbitals.

sp^2 Hybrid Orbitals

Carbon's group 13 neighbor, boron, has *four* orbitals but only *three* electrons in its valence shell. For most boron compounds, the appropriate hybridization scheme combines the 2*s* and two 2*p* orbitals into *three* **sp^2 hybrid orbitals** and leaves one *p* orbital unhybridized. Valence-shell orbital diagrams for this hybridization scheme for boron are shown here, and the scheme is further outlined in Figure 11-9.

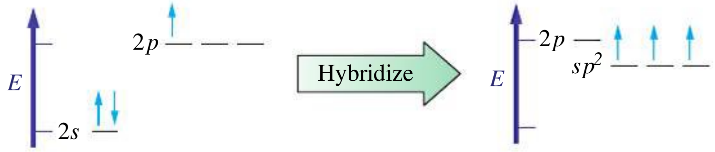
◀ FIGURE 11-9
The sp^2 hybridization scheme

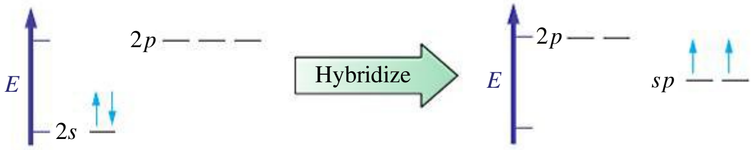


The sp^2 hybridization scheme corresponds to trigonal-planar electron-group geometry and 120° bond angles, as in BF_3. Note again that in the hybridization schemes of valence-bond theory, the number of orbitals is conserved; that is, in an sp^2 hybridized atom there are still four orbitals: three sp^2 hybrids and an unhybridized *p* orbital.

sp Hybrid Orbitals

Boron's group 2 neighbor, beryllium, has *four* orbitals and only *two* electrons in its valence shell. In the hybridization scheme that best describes certain *gaseous* beryllium compounds, the 2*s* and one 2*p* orbital of Be are hybridized into *two* ***sp* hybrid orbitals**, and the remaining two 2*p* orbitals are left unhybridized. Valence-shell orbital diagrams of beryllium in this hybridization scheme are shown here, and the scheme is further outlined in Figure 11-10.

▶ In hybridization, molecular orbital, and valence-bond theory, not only is energy conserved, but also the number of orbitals is conserved. sp^2 hybrid orbitals still have one *p* orbital left over and this is particularly important for carbon. Carbon readily uses the leftover *p* orbitals to form π bonds (see page 461). In contrast, silicon, the element one below carbon, does not use the *p* orbitals as readily because silicon is larger and the *p* orbitals do not project out far enough to form double and triple bonds.



The *sp* hybridization scheme corresponds to a linear electron-group geometry and a 180° bond angle, as in $BeCl_2(g)$.

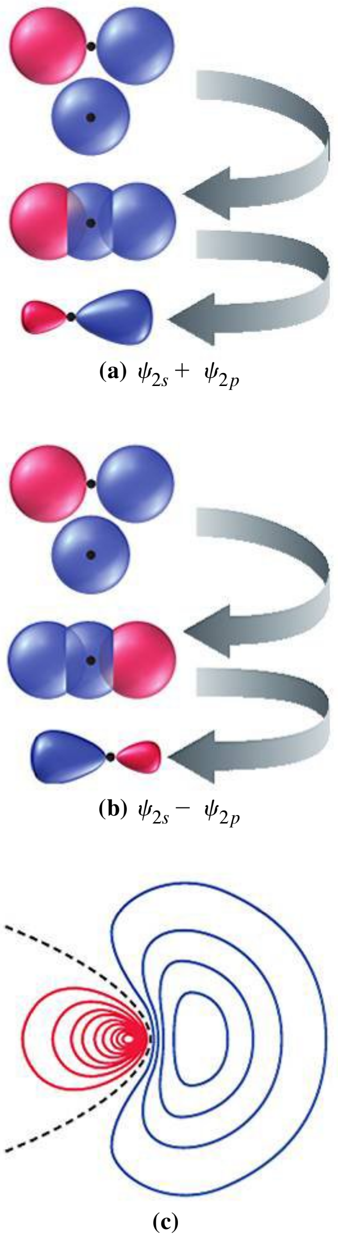
The *sp* hybridization scheme

11-2 ARE YOU WONDERING...

How the atomic orbitals mix to form a hybrid orbital?

A hybrid atomic orbital is the result of a mathematical combination (algebraic addition and subtraction) of the wave functions describing two or more atomic orbitals. When the algebraic functions that represent *s* and *p* orbitals are added, a new function is produced; this is an *sp* hybrid. When the same algebraic functions are subtracted, another new function is produced; this is a second *sp* hybrid. The hybridization process is shown in Figure 11-11, where we see the consequence of the phase of the *p* orbital when we add the *s* and *p* orbitals: The negative phase of the *p* orbital cancels part of the positive *s* orbital. This leads to the teardrop-shaped orbital pointing in the direction of the positive lobe of the *p* orbital. As shown in Figure 11-11, subtraction of the two orbitals reverses this situation. The two ways of combining an *s* and a *p* orbital generate the two equivalent *sp* hybrid orbitals, each having its greatest amplitude (or electron density if we square the amplitude) in a direction 180° from the other. A similar procedure is used to construct the three sp^2 and the four sp^3 hybrid orbitals, although the combinations of orbitals are slightly more complicated.



(a) $\psi_{2s} + \psi_{2p}$

(b) $\psi_{2s} - \psi_{2p}$

(c)

▲ FIGURE 11-11
The formation of an *sp* hybrid orbital

sp^3d and sp^3d^2 Hybrid Orbitals

To describe hybridization schemes that correspond to the 5- and 6-electron-group geometries of VSEPR theory, we need to go beyond the *s* and *p* subshells of the valence shell, and traditionally this has meant including *d*-orbital contributions. We can achieve the *five* half-filled orbitals of phosphorus to account for the five P—Cl bonds in PCl_5 and its trigonal-bipyramidal molecular geometry through the hybridization of the *s*, three *p*, and one *d* orbital of the valence shell into *five* **sp^3d hybrid orbitals**.

sp^3d

We can achieve the *six* half-filled orbitals of sulfur to account for the six S—F bonds in SF_6 and its octahedral molecular geometry through the hybridization of the *s*, three *p*, and two *d* orbitals of the valence shell into *six* **sp^3d^2 hybrid orbitals**.

sp^3d^2

The sp^3d and sp^3d^2 hybrid orbitals and two of the molecular geometries in which they can occur are featured in Figure 11-12.

We have previously stated that hybridization is not a real phenomenon, but an after-the-fact rationalization of an experimentally determined result. Perhaps there is no better illustration of this point than the issue of the sp^3d and sp^3d^2 hybrid orbitals. In discussing the concept of the expanded valence shell in Chapter 10, we noted that valence-shell expansion would seem to require *d* electrons in bonding schemes, but recent theoretical considerations cast serious doubt on *d*-electron participation. The same doubt, of course, extends to the use of *d* orbitals in hybridization schemes.

Despite the difficulty posed by hybridization schemes involving *d* orbitals, the *sp*, sp^2, and sp^3 hybridization schemes are well established and very commonly encountered, particularly among the second-period elements.

11-2 CONCEPT ASSESSMENT

Give the formula of a compound or ion composed of arsenic and fluorine in which the arsenic atom has a sp^3d^2 hybridization state.

Hybrid Orbitals and the Valence-Shell Electron-Pair Repulsion (VSEPR) Theory

In the previous section, we used either the experimental geometry or the geometry predicted by VSEPR theory to help us decide on the appropriate hybridization scheme for the central atom. The concept of hybridization arose before the formulation of the VSEPR theory as we used it in Chapter 10. In 1931, Linus Pauling introduced the concept of hybridization of orbitals to account for the known geometries of CH_4, H_2O, and NH_3. It was first suggested by Nevil Vincent Sidgwick and Herbert Marcus Powell in 1940 that molecular geometry was determined by the arrangement of electron pairs in the valence shell, and this suggestion was subsequently developed into the set of rules known as VSEPR by Ronald Gillespie and Ronald Nyholm in 1957. The advantage of VSEPR is that it has a predictive capability based on Lewis structures, whereas hybridization schemes, as described here, require a prior knowledge of the molecular geometry. So how should we proceed to describe the bonding in molecules? We can choose the likely hybridization scheme for a central atom in a structure in the valence-bond method by

- writing a plausible Lewis structure for the species of interest
- using VSEPR theory to predict the probable electron-group geometry of the central atom

- selecting the hybridization scheme corresponding to the electron-group geometry

The procedure outlined above is illustrated in Figure 11-13 using the molecule SF_4 as an example.

As suggested by Table 11.1, the hybridization scheme adopted for a central atom should be the one producing the same number of hybrid orbitals as there are valence-shell electron groups, and in the same geometric orientation. Thus, an sp^3 hybridization scheme for the central atom predicts that four hybrid orbitals are distributed in a tetrahedral fashion. This results in molecular structures that are tetrahedral, trigonal-pyramidal, or angular, depending on how many hybrid orbitals are involved in orbital overlap and how many contain lone-pair electrons, corresponding to the VSEPR notations AX_4, AX_3E, and AX_2E_2 respectively.

The *s* and *p* orbital hybridization schemes are especially important in organic compounds, whose principal elements are C, O, and N, in addition to H. We will consider some important applications to organic chemistry in the next section.

EXAMPLE 11-2 Proposing a Hybridization Scheme to Account for the Shape of a Molecule

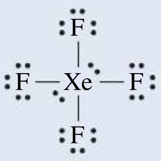
Predict the shape of the XeF_4 molecule and a hybridization scheme consistent with this prediction.

Analyze

Follow the procedure outlined in Figure 11-13.

Solve

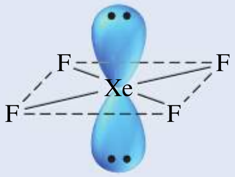
1. **Write a plausible Lewis structure.** The Lewis structure we write must account for 36 valence electrons—*eight* from the Xe atom and *seven* each from the *four* F atoms. To place this many electrons in the Lewis structure, we must expand the valence shell of the Xe atom to accommodate 12 electrons. The Lewis structure is



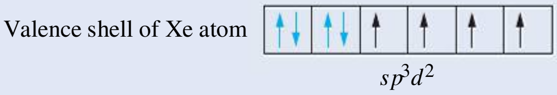
2. **Use the VSEPR theory to establish the electron-group geometry of the central atom.** From the Lewis structure, we see that there are *six* electron groups around the Xe atom. Four electron groups are bond pairs and two are lone pairs. The electron-group geometry for *six* electron groups is *octahedral*.

(continued)

3. **Describe the molecular geometry.** The VSEPR notation for XeF_4 is AX_4E_2, and the molecular geometry is *square-planar* (see Table 10.1). The four pairs of bond electrons are directed to the corners of a square, and the lone pairs of electrons are found above and below the plane of the Xe and F atoms, as shown here.



4. **Select a hybridization scheme that corresponds to the VSEPR prediction.** The only hybridization scheme consistent with an octahedral distribution of *six* electron groups is sp^3d^2. The orbital diagram for this scheme shows clearly that *four* of the eight valence electrons of the central Xe atom singly occupy four of the sp^3d^2 orbitals. The remaining *four* valence electrons of the atom occupy the remaining two sp^3d^2 orbitals as lone pairs. These are the lone pairs of electrons situated above and below the plane of the Xe and F atoms in the above sketch.



Assess

Note that the number of electron pairs in the electron-group geometry dictates how many orbitals are used in the hybridization scheme. We see that a combination of VSEPR and hybridization theory is an appealing way to describe the shape of and bonding in a molecule.

PRACTICE EXAMPLE A: Describe the molecular geometry and propose a plausible hybridization scheme for the central atom in the ion Cl_2F^+.

PRACTICE EXAMPLE B: Describe the molecular geometry and propose a plausible hybridization scheme for the central atom in the ion BrF_4^+.

11-3 ARE YOU WONDERING...

Whether to use the VSEPR method (Section 10-7) or the valence-bond method in rationalizing the geometric shape of a molecule?

There is no "correct" method for describing molecular structures. The only correct information is the experimental evidence from which the structure is established. Once this experimental evidence is in hand, you may find it easier to rationalize this evidence by one method or another. For H_2S, the valence-bond method, which suggests a bond angle of 90°, seems to do a better job of explaining the observed 92° bond angle than does the VSEPR theory. For the Lewis structure, $\mathrm{H}-\ddot{\underset{\bullet\bullet}{\mathrm{S}}}-\mathrm{H}$, VSEPR theory predicts a tetrahedral electron-group geometry, which in turn suggests a tetrahedral bond angle—that is, 109.5°. However, by modifying this initial VSEPR prediction to accommodate lone-pair–lone-pair and lone-pair–bond-pair repulsions (see page 427), the predicted bond angle is less than 109.5°.

VSEPR theory gives reasonably good results in the majority of cases. Unless you have specific information to suggest otherwise, describing a molecular shape with the VSEPR theory is a good bet. It is important to remember that both the VSEPR and valence-bond methods are simply models we use to rationalize the shapes and bonding of polyatomic molecules and as such, should be viewed with a critical eye, always keeping experimental results in sight.

KEEP IN MIND

that the VSEPR method uses empirical data to give an approximate molecular geometry, whereas the valence-bond method relates to the orbitals used in bonding based on a given geometry.

11-3 CONCEPT ASSESSMENT

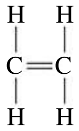
What hybridization do you expect for the central atom in a molecule that has a square-pyramidal geometry?

11-4 Multiple Covalent Bonds

Two different types of orbital overlap occur when multiple bonds are described by the valence-bond method. In our discussion we will use as specific examples the carbon-to-carbon double bond in ethylene, C_2H_4, and the carbon-to-carbon triple bond in acetylene, C_2H_2.

Bonding in C_2H_4

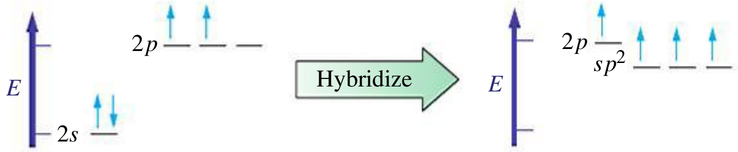
Ethylene has a carbon-to-carbon double bond in its Lewis structure.



$$\begin{array}{ccc} \mathrm{H} & & \mathrm{H} \\ | & & | \\ \mathrm{C} & = & \mathrm{C} \\ | & & | \\ \mathrm{H} & & \mathrm{H} \end{array}$$

Ethylene is a planar molecule with 120° H—C—H and H—C—C bond angles. VSEPR theory treats each C atom as being surrounded by *three* electron groups in a trigonal-planar arrangement. VSEPR theory does *not* dictate that the two —CH_2 groups be coplanar, but as we will see, valence-bond theory does.

The hybridization scheme that produces a set of hybrid orbitals with a trigonal-planar orientation is sp^2. The valence-shell orbital diagrams of carbon for this scheme are



The $sp^2 + p$ orbital set is pictured in Figure 11-14. One of the bonds between the carbon atoms results from the overlap of sp^2 hybrid orbitals from each atom. This overlap occurs along the line joining the nuclei of the

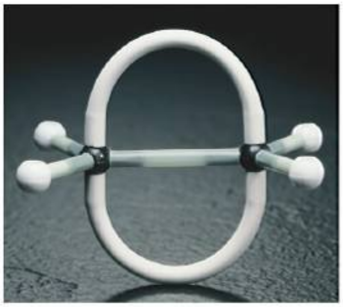
Computed π orbitals of ethylene

◀ FIGURE 11-14
Sigma (σ) and pi (π) bonding in C_2H_4
The purple orbitals are sp^2 hybrid orbitals; the red and blue orbitals are $2p$, with the colors indicating their phase. The sp^2 hybrid orbitals overlap along the line joining the bonded atoms—a σ bond. The $2p$ orbitals overlap in a side-to-side fashion and form a π bond. Notice that the phase of the p orbitals is retained.



▲ FIGURE 11-15
Ball-and-stick model of ethylene, C_2H_4
The H—C—H and C—C—H bond angles are 120°. The model also distinguishes between the σ bond between the C atoms (the straight plastic tube) and the π bond extending above and below the plane of the molecule. The picture of the π bond suggested by the white plastic "arches" is somewhat distorted, but the model does convey the idea that the π bond places a high electron charge density above and below the plane of the molecule.

two atoms. Orbitals that overlap in this end-to-end fashion produce a **sigma bond**, designated **σ bond**. Figure 11-14 shows that a second bond between the C atoms results from the overlap of the unhybridized *p* orbitals. In this bond, there is a region of high electron charge density above and below the plane of the carbon and hydrogen atoms. The bond produced by this side-to-side overlap of two parallel orbitals is called a **pi bond**, designated **π bond**.

The ball-and-stick model in Figure 11-15 illustrates bonding in ethylene. It helps to show that

- the shape of a molecule is determined only by the orbitals forming σ bonds (the σ-bond framework).
- rotation about the double bond is severely restricted. In the ball-and-stick model, we could easily twist or rotate the terminal H atoms about the *s* bonds that join them to a C atom. To twist one $—CH_2$ group out of the plane of the other, however, would reduce the amount of overlap of the *p* orbitals and weaken the π bond. The double bond is rigid, and the C_2H_4 molecule is planar.

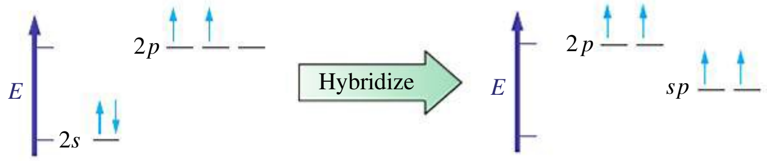
Additionally, in carbon-to-carbon multiple bonds, the σ bond involves more extensive overlap than does the π bond. As a result, a carbon-to-carbon double bond ($\sigma + \pi$) is stronger than a single bond (σ), but not twice as strong (from Table 10.3, C—C, 347 kJ/mol; C═C, 611 kJ/mol; C≡C, 837 kJ/mol).

KEEP IN MIND

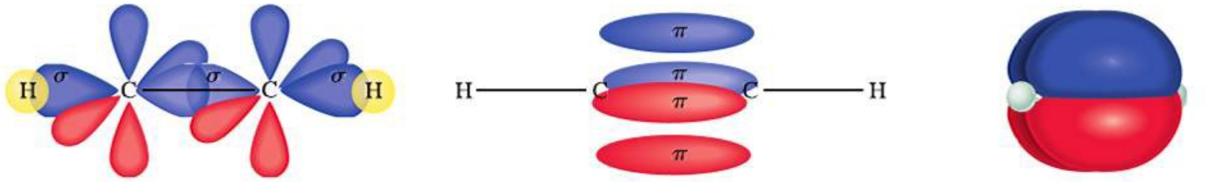
that only one of the bonds in a multiple bond is a σ bond; the others are π bonds—one π bond in a double bond and two in a triple bond.

Bonding in C_2H_2

Bonding in acetylene, C_2H_2, is similar to that in C_2H_4, but with these differences: The Lewis structure of C_2H_2 features a triple covalent bond, H—C≡C—H. The molecule is *linear*, as found by experiment and as expected from VSEPR theory. A hybridization scheme to produce hybrid orbitals in a linear orientation is *sp*. The valence-shell orbital diagrams representing *sp* hybridization are



In the triple bond in C_2H_2, one of the carbon-to-carbon bonds is a σ bond and *two* are π bonds, as suggested in Figure 11-16.



Formation of σ bonds
Formation of π bonds
Computed π orbitals of acetylene

▲ FIGURE 11-16
σ and π bonding in C_2H_2
The σ-bond framework joins the atoms H—C—C—H through 1*s* orbitals of the H atoms and *sp* orbitals of the C atoms. There are two π bonds. Each π bond consists of two parallel cigar-shaped segments. The four segments shown actually merge into a hollow cylindrical shell with the carbon-to-carbon σ bond as its axis. The computed model is shown on the right.

EXAMPLE 11-3 Proposing Hybridization Schemes Involving σ and π Bonds

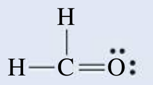
Formaldehyde gas, H_2CO, is used in the manufacture of plastics; in aqueous solution, it is the familiar biological preservative called formalin. Describe the molecular geometry and a bonding scheme for the H_2CO molecule.

Analyze

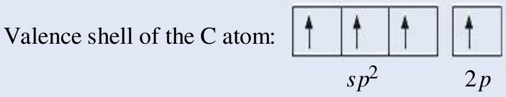
The number of electron groups around central atoms dictates the number of atomic orbitals that undergo hybridization. The carbon atom in formaldehyde contains three electron groups (remember, a double bond is counted as one group), which means that three atomic orbitals are hybridized to form three sp^2 orbitals. We will follow the procedure shown in Figure 11-13.

Solve

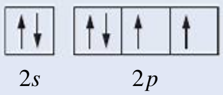
1. **Write the Lewis structure.** C is the central atom, and H and O are terminal atoms. The total number of valence electrons is 12. Note that this structure requires a carbon-to-oxygen double bond.

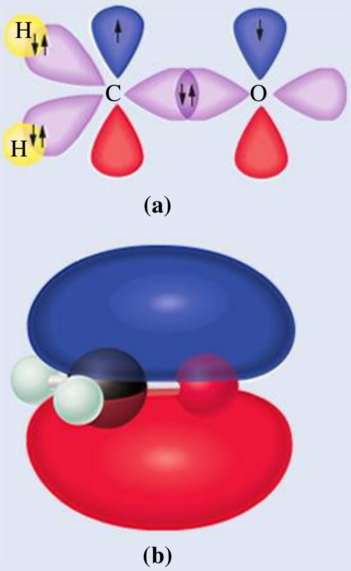


2. **Determine the electron-group geometry of the central C atom.** The σ-bond framework is based on three electron groups around the central C atom. VSEPR theory, based on the distribution of three electron groups, suggests a trigonal-planar molecule with 120° bond angles.
3. **Identify the hybridization scheme that conforms to the electron-group geometry.** A trigonal-planar orientation of orbitals is associated with sp^2 hybrid orbitals.
4. **Identify the orbitals of the central atom that are involved in orbital overlap.** The C atom is hybridized to produce the orbital set $sp^2 + p$, as in C_2H_4. Two of the sp^2 hybrid orbitals are used to form σ bonds with the H atoms. The remaining sp^2 hybrid orbital is used to form a σ bond with oxygen. The unhybridized p orbital of the C atom is used to form a π bond with O.



5. **Sketch the bonding orbitals of the central and terminal atoms.** The bonding orbitals of the central C atom described above are pictured in Figure 11-17(a). The sp^2 hybrid orbitals are shown in lavender, and the pure p orbitals, in blue and red. The H atoms have only 1s orbitals available for bonding. For oxygen, the half-filled 2p orbital can be used for end-to-end overlap in the σ bond to carbon, and a half-filled 2p orbital can participate in the side-to-side overlap leading to a π bond. Thus, the valence-shell orbital diagram we can use for oxygen is





▲ FIGURE 11-17
Bonding and structure of the H_2CO molecule—Example 11-3 illustrated
(a) The orbital set $sp^2 + p$ is used for the C atom, 1s orbitals for H, and two half-filled 2p orbitals for O. For simplicity, only bonding orbitals of the valence shells are shown. **(b)** Computed π orbital for the CO group.

Assess

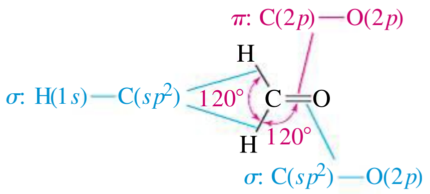
The bonding and structure of the formaldehyde molecule are suggested by the three-dimensional sketch in Figure 11-17(b).

One of the main purposes of hybridizing orbitals is to describe molecular geometry (for example, bond angles), and so we generally apply hybridization schemes only to central atoms, although hybridization of terminal atoms (except H) may also be invoked.

The H_2CO molecule has four bonds around carbon (three σ bonds and one π bond). These four bonds are used to bond three groups: two H atoms and one O atom. In determining the electron-group geometry and bond angles around a particular atom, we focus on the number of σ bonds and lone pairs, if any.

PRACTICE EXAMPLE A: Describe a plausible bonding scheme and the molecular geometry of dimethyl ether, CH_3OCH_3.

PRACTICE EXAMPLE B: Acetic acid, the acidic component of vinegar, has the formula CH_3COOH. Describe the molecular geometry and a bonding scheme for this molecule.



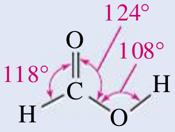
▶ FIGURE 11-18
Bonding in H_2CO—a schematic representation

Drawing three-dimensional sketches to show orbital overlaps, as in Figure 11-17(b), is not easy. A simpler, two-dimensional representation of the bonding scheme for formaldehyde is shown in Figure 11-18. Bonds between atoms are drawn as straight lines. They are labeled σ or π, and the orbitals that overlap are indicated.

We have stressed a Lewis structure as the first step in describing a bonding scheme. Sometimes the starting point is a description of the species obtained by experiment. Example 11-4 illustrates such a case.

EXAMPLE 11-4 Using Experimental Data to Assist in Selecting a Hybridization and Bonding Scheme

Formic acid, HCOOH, is an irritating substance released by ants when they bite (*formica* is Latin, meaning "ant"). A structural formula with bond angles is given here. Propose a hybridization and bonding scheme consistent with this structure.

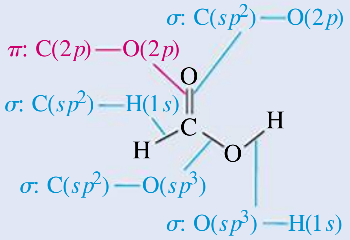


Analyze

When we are given the bond angles for a molecule, we know the hybridization scheme is dictated by the bond angles of that atom; for example, if the bond angle is close to 109.5°, we expect sp^3 hybridization.

Solve

The 118° H—C—O bond angle on the left is very nearly the 120° angle for a trigonal-planar distribution of three groups of electrons. This requires an sp^2 hybridization scheme for the C atom. The 124° O—C—O bond angle is also close to the 120° expected for sp^2 hybridization. The C—O—H bond angle of 108° is close to the tetrahedral angle—109.5°. The O atom on the right employs an sp^3 hybridization scheme. The four σ and one π bonds and the orbital overlaps producing them are indicated in Figure 11-19.

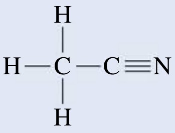


▲ FIGURE 11-19
Bonding and structure of HCOOH—Example 11-4 illustrated

Assess

The structure shown in Figure 11-19 does not show the lone pair electrons; they are there implicitly. We can infer the presence of the lone pairs from the observed bond angles. If we had been given just the skeletal structure of this molecule, we would have deduced the sp^3 hybridization at the oxygen atom by using a Lewis structure and VSEPR theory.

PRACTICE EXAMPLE A: Acetonitrile is an industrial solvent. Propose a hybridization and bonding scheme consistent with its structure.



$$\mathrm{H{-}\underset{\underset{\displaystyle H}{|}}{\overset{\overset{\displaystyle H}{|}}{C}}{-}C{\equiv}N}$$

PRACTICE EXAMPLE B: A reference source on molecular structures lists the following data for dinitrogen monoxide (nitrous oxide), N_2O: Bond lengths: N—N = 113 pm; N—O = 119 pm; bond angle = 180°. Show that the Lewis structure of N_2O is a resonance hybrid of two contributing structures, and describe a plausible hybridization and bonding scheme for each.

11-4 CONCEPT ASSESSMENT

The molecule diazine has the molecular formula N_2H_2. What is the hybridization of the nitrogen and does the molecule contain a double or triple bond?

11-5 Molecular Orbital Theory

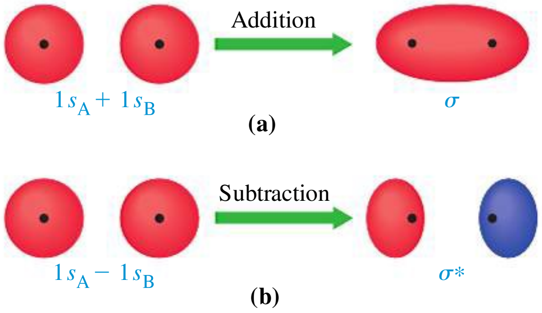
Lewis structures, VSEPR theory, and the valence-bond method make a potent combination for describing covalent bonding and molecular structures. They are satisfactory for most of our purposes. Sometimes, however, chemists need a greater understanding of molecular structures and properties than these methods provide. None of these methods, for instance, provides an explanation of the electronic spectra of molecules, why oxygen is paramagnetic, or why H_2^+ is a stable species. To address these questions, we need a different method of describing chemical bonding.

This method, called **molecular orbital theory**, starts with a simple picture of molecules, but it quickly becomes complex in its details. We can provide only an overview here. The theory assigns the electrons in a molecule to a series of orbitals that belong to the molecule as a whole. These are called molecular orbitals. Like atomic orbitals, molecular orbitals are mathematical functions, but we can relate them to the probability of finding electrons in certain regions of a molecule. Also like an atomic orbital, a molecular orbital can accommodate just two electrons, and the electrons must have opposing spins.

Earlier in this chapter, we described the approach of two H atoms toward each other to form a chemical bond (see Figure 11-2). What happens to the atomic orbitals as the two H atoms merge to form a chemical bond? As the atoms approach, the two 1*s* wave functions combine; they do this by interfering constructively or destructively. Constructive interference corresponds to adding the two mathematical functions (the positive sign puts the waves in phase), while destructive interference corresponds to subtracting the two mathematical functions (the minus sign puts the waves out of phase). These two types of combination are illustrated in Figure 11-20.

How do we interpret these two different combinations of wave functions? The constructive interference (addition) of the two wave functions leads to a greater probability of finding the electron between the nuclei. The increased electron charge density between the nuclei causes them to draw closer together, forming a chemical bond. The electron probability or electron charge density in the σ_{1s} orbital is $(1s_A + 1s_B)^2$, the square of the new function $(1s_A + 1s_B)$, where $1s_A$ and $1s_B$ are the two 1*s* orbitals on the two H atoms. The square is $1s_A^2 + 1s_B^2$ *plus* the extra term $2 \times 1s_A 1s_B$, which is the extra charge density between the nuclei.

The result of this constructive interference is a **bonding molecular orbital** because it places a high electron charge density between the two nuclei. A high electron charge density between atomic nuclei reduces repulsions between the positively charged nuclei and promotes a strong bond. This bonding molecular orbital, designated σ_{1s}, is at a *lower* energy than the 1*s* atomic orbitals.



◀ FIGURE 11-20
Formation of bonding and antibonding orbitals
(a) The addition of two 1*s* orbitals in phase to form a σ_{1s} molecular orbital. This orbital produces electron density between the nuclei, leading to a chemical bond. **(b)** The addition of two 1*s* orbitals out of phase to produce a σ_{1s}^* antibonding orbital. This orbital has a nodal plane perpendicular to the internuclear axis, as do all antibonding orbitals.

The molecular orbital formed by the destructive interference (subtraction) of the two 1*s* orbitals leads to reduced electron probability between the nuclei. This produces an **antibonding molecular orbital**, designated by a superscript asterisk (*), because it places a very low electron charge density between the two nuclei. The electron probability or electron charge density in the σ^*_{1s} orbital is $(1s_A - 1s_B)^2$, the square of the new function $(1s_A - 1s_B)$, where $1s_A$ and $1s_B$ are the 1*s* orbitals on the two H atoms. The square is $1s_A^2 + 1s_B^2$ *minus* the extra term $2 \times 1s_A 1s_B$ which is the loss of charge density between the nuclei. Notice that $-2 \times 1s_A 1s_B$ here exactly balances the extra density $(+2 \times 1s_A 1s_B)$ in the molecular orbital formed by addition of the atomic functions.

With a low electron charge density between atomic nuclei, the nuclei are not screened from each other, strong repulsions occur, and the bond is weakened (hence the term "antibonding"). This antibonding molecular orbital, designated σ^*_{1s}, is at a *higher* energy than the 1*s* atomic orbitals.

The combination of two 1*s* orbitals of H atoms into two molecular orbitals in a H_2 molecule is summarized in Figure 11-21.

▶ Molecular orbital theory states that the number of molecular orbitals formed is equal to the number of atomic orbitals combined.

Basic Ideas Concerning Molecular Orbitals

Here are some useful ideas about molecular orbitals and how electrons are assigned to them.

1. The number of molecular orbitals (MOs) formed is equal to the number of atomic orbitals combined.
2. Of the two MOs formed when two atomic orbitals are combined, one is a *bonding* MO at a *lower* energy than the original atomic orbitals. The other is an *antibonding* MO at a *higher* energy.

▲ FIGURE 11-21
The interaction of two hydrogen atoms according to molecular theory
The energy of the bonding σ_{1s} molecular orbital is lower and that of the antibonding σ^*_{1s} molecular orbital is higher than the energies of the 1*s* atomic orbitals. Electron charge density in a bonding molecular orbital is high in the internuclear region. In an antibonding orbital, it is high in parts of the molecule away from the internuclear region.

3. In ground-state configurations, electrons enter the lowest energy MOs available.
4. The maximum number of electrons in a given MO is two (Pauli exclusion principle, page 339).
5. In ground-state configurations, electrons enter MOs of identical energies *singly* before they pair up (Hund's rule, page 339).

A stable molecular species has more electrons in bonding orbitals than in antibonding orbitals. For example, if the excess of bonding over antibonding electrons is *two*, this corresponds to a *single* covalent bond in Lewis theory. In molecular orbital theory, we say that the bond order is 1. **Bond order** is one-half the difference between the number (no.) of bonding and antibonding electrons (e^-), that is,

$$\text{bond order} = \frac{\text{no. of } e^- \text{ in bonding MOs} - \text{no. of } e^- \text{ in antibonding MOs}}{2} \qquad \textbf{(11.1)}$$

KEEP IN MIND

that equation (11.1) is only valid for diatomic molecules

Diatomic Molecules of the First-Period Elements

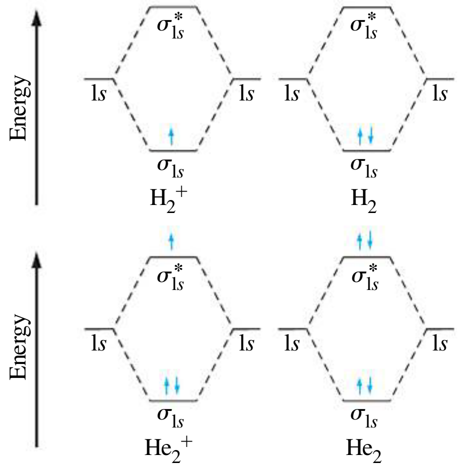
Let's use the ideas just outlined to describe some molecular species of the first-period elements, H and He (Fig. 11-22).

H_2^+ This species has a single electron. It enters the σ_{1s} orbital, a bonding molecular orbital. Using equation (11.1), we see that the bond order is $(1 - 0)/2 = \frac{1}{2}$. This is equivalent to a one-electron, or *half*, bond, a bond type that is not easily described by the Lewis theory.

H_2 This molecule has two electrons, both in the σ_{1s} orbital. The bond order is $(2 - 0)/2 = 1$. With Lewis theory and the valence-bond method, we describe the bond in H_2 as single covalent.

He_2^+ This ion has three electrons. Two electrons are in the σ_{1s} orbital, and one is in the σ^*_{1s} orbital. This species exists as a stable ion with a bond order of $(2 - 1)/2 = \frac{1}{2}$.

He_2 Two electrons are in the σ_{1s} orbital, and two are in the σ^*_{1s}. The bond order is $(2 - 2)/2 = 0$. No bond is produced—He_2 is not a stable species.



▲ FIGURE 11-22

Molecular orbital diagrams for the diatomic molecules and ions of the first-period elements

The 1s energy levels of the isolated atoms are shown to the left and right of each diagram. The line segments in the middle represent the molecular orbital energy levels—lower than the 1s levels for σ_{1s} and higher than the 1s levels for σ^*_{1s}.

EXAMPLE 11-5 Relating Bond Energy and Bond Order

The bond energy of H_2 is 436 kJ/mol. Estimate the bond energies of H_2^+ and He_2^+.

Analyze

The strength of a bond is directly proportional to its bond order. If we double the bond order, we double the strength (approximately).

Solve

The bond order in H_2 is 1, equivalent to a single bond. In both H_2^+ and He_2^+, the bond order is $\frac{1}{2}$. We should expect the bonds in these two species to be only about half as strong as in H_2—about 220 kJ/mol.

Assess

The actual bond energies are 255 kJ/mol and 251 kJ/mol for H_2^+ and He_2^+, respectively, showing that our approximation is reasonable.

PRACTICE EXAMPLE A: The bond energy of Li_2 is 106 kJ/mol. Estimate the bond energy of Li_2^+.

PRACTICE EXAMPLE B: Do you think the ion H_2^- is stable? Explain.

11-5 CONCEPT ASSESSMENT

A ground state H_2 molecule can absorb electromagnetic radiation to form the ion H_2^+ or an excited state with an electron promoted to the σ^*_{1s} orbital. Which process requires the greater amount of energy? Which species is most stable?

Molecular Orbitals of the Second-Period Elements

For diatomic molecules and ions of H and He, we had to combine only 1*s* orbitals. In the second period, the situation is more interesting because we must work with both 2*s* and 2*p* orbitals. This results in *eight* molecular orbitals. Let's see how this comes about.

▶ In Figure 11-23, the simplified *p* orbitals are used rather than their probability-density plots because our emphasis is on the phases of the orbitals that are being combined.

The molecular orbitals formed by combining 2*s* atomic orbitals are similar to those from 1*s* atomic orbitals, except they are at a higher energy. The situation for combining 2*p* atomic orbitals, however, is different. Two possible ways for 2*p* atomic orbitals to combine into molecular orbitals are shown in Figure 11-23: end-to-end and side-to-side. The best overlap for *p* orbitals is along a straight line (that is, end-to-end). This combination produces σ-type molecular orbitals: σ_{2p} and σ^*_{2p}. In forming the bonding and antibonding combinations along the internuclear axis, we must take into account the phase of the 2*p* orbitals. We set up the atomic orbitals as shown in Figure 11-23(a), with the positive (blue) lobe of each function pointing to the internuclear region. Then, since the wave functions are in phase, the addition of the two wave functions leads to an increase of electron density in the internuclear region and produces a σ_{2p} orbital. When the two atomic orbitals are set up as shown in Figure 11-23(b), with lobes of opposite phase pointing into the internuclear region, a nodal plane midway between the nuclei is formed, leading to an antibonding σ^*_{2p} orbital.

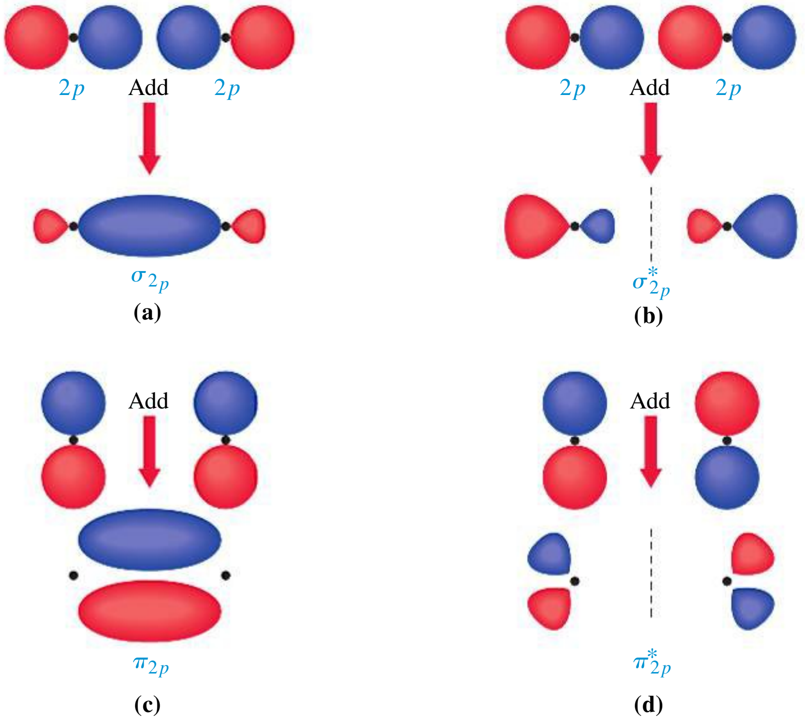
KEEP IN MIND

that the different colors of the orbitals depicted in these various figures represent the phases of the orbitals.

KEEP IN MIND

that subtracting two wave functions that are in phase is equivalent to *adding* the same functions when they are out of phase.

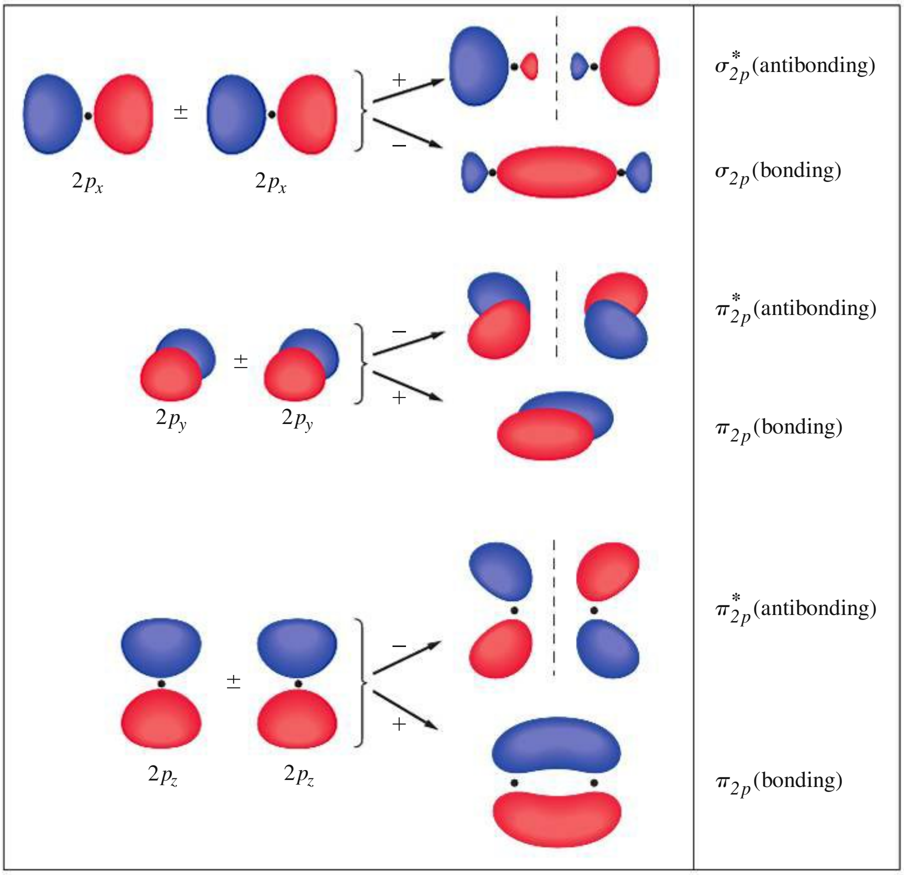
Only one pair of *p* orbitals can combine in an end-to-end fashion. The other two pairs must combine in a parallel or side-to-side fashion to produce π-type molecular orbitals: π_{2p} and π^*_{2p}. The two possible ways for the side-to-side combination of a pair of 2*p* orbitals are shown in Figure 11-23(c and d). The π_{2p} bonding orbital (Fig. 11-23c) is formed by adding the *p* orbital on one nucleus to a *p* orbital on the other nucleus, in such a way that the positive and negative lobes of one orbital are in phase with the positive and negative lobes of the other *p* orbital on the other nucleus. This produces additional electron density between the nuclei, but in a much less direct way than in the σ orbital because the additional electron density is not found along the internuclear axis. Typically, the π bond is weaker than the σ bond. The π^*_{2p} antibonding orbital is



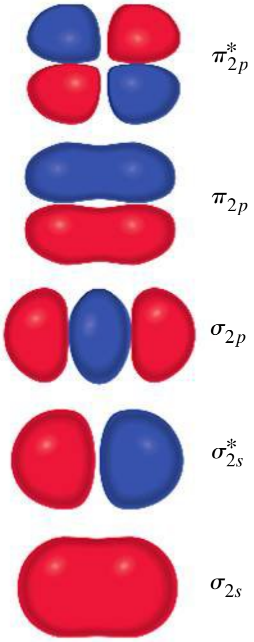
◀ FIGURE 11-23
Formation of bonding and antibonding orbitals from 2*p* orbitals
(a) The addition of two 2*p* orbitals in phase along the internuclear axis to form a σ_{2p} molecular orbital. This orbital produces electron density between the nuclei, leading to a chemical bond. **(b)** The addition of two 2*p* orbitals out of phase to produce an antibonding σ^*_{2p} orbital. This orbital has a nodal plane perpendicular to the internuclear axis, as do all antibonding orbitals. **(c)** The addition of two 2*p* orbitals in phase perpendicular to the internuclear axis to form a π_{2p} molecular orbital. This orbital produces electron density between the nuclei, contributing to a multiple chemical bond. **(d)** The addition of two 2*p* orbitals out of phase to produce a π^*_{2p} antibonding orbital with a nodal plane.

formed by subtracting the two *p* orbitals perpendicular to the internuclear axes, as shown in Figure 11-23(d). Now, in addition to the nodal plane that contains the nuclei, a node is formed between the nuclei, and this is a characteristic of antibonding character. There are actually *four* π-type molecular orbitals (two bonding and two antibonding) because there are *two* pairs of 2*p* atomic orbitals arranged in a parallel fashion. Figure 11-24 depicts the approximate probability

◀ Note that assigning blue to the positive lobe is quite arbitrary. The important aspect is that the orbitals are in phase to create a bonding orbital.



◀ FIGURE 11-24
Combining 2*p* atomic orbitals
These diagrams suggest the electron charge distributions for several orbitals. They are not exact in all details. A dashed line is used to represent a nodal plane that is perpendicular to the internuclear axis.



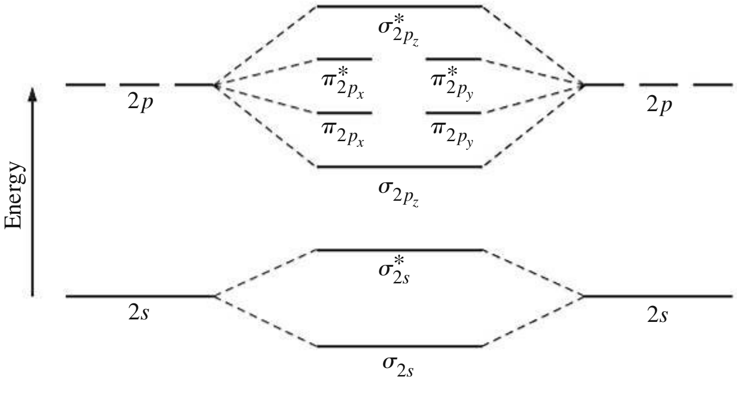
Some computed molecular orbitals of F_2

distributions based on the orbital interactions described in Figure 11-23. Again, we see that bonding molecular orbitals place a high electron charge density between the atomic nuclei. In antibonding molecular orbitals, there are nodal planes between the nuclei, where the electron charge density falls to zero.

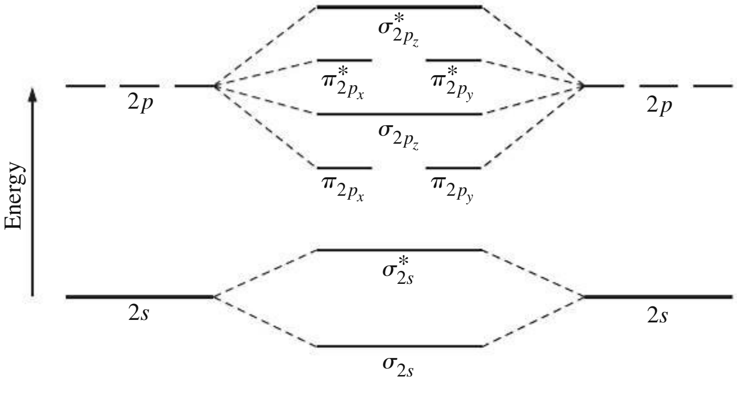
The energy-level diagram for the molecular orbitals formed from atomic orbitals of the second principal electronic shell is related to the atomic orbital energy levels. For example, molecular orbitals formed from 2*s* orbitals are at a lower energy than those formed from 2*p* orbitals—the same relationship as between the 2*s* and 2*p* atomic orbitals. Another expectation is that σ-type bonding orbitals should have lower energies than π-type because end-to-end overlap of 2*p* orbitals should be more extensive than side-to-side overlap, resulting in a lower energy. This ordering is shown in Figure 11-25(a). In constructing this energy-level diagram, we have made the assumption that *s* orbitals mix only with *s* orbitals and *p* orbitals mix only with *p* orbitals. However, if we use this assumption for some diatomic molecules, we will make predictions that do not match experimental results.

We need to take into account the fact that both the 2*s* and 2*p* orbitals form molecular orbitals (σ_{2s} and σ_{2p}) that produce electron density in the same region between the nuclei. These two σ orbitals are of such similar energy and shape that they themselves mix to form modified σ orbitals. The modified σ orbitals each contain a fraction of the original σ_{2s} and σ_{2p}. The modified σ_{2s} (with some σ_{2p} mixed in) goes down in energy, and the modified σ_{2p} (with some σ_{2s} mixed in) goes up in energy, producing a different ordering of energy levels. The important aspect of this mixing is that the modified σ_{2p} is pushed up in energy above the π_{2p} orbitals (Fig. 11-25b).

For the molecular orbitals in O_2 and F_2, the situation is as expected because the energy difference between the 2*s* and 2*p* orbitals is large, and little *s* and *p* mixing takes place; that is, the σ_{2s} and σ_{2p} orbitals are *not* modified as



(a) $Z \geq 8$



(b) $Z \leq 7$

▶ FIGURE 11-25
The two possible molecular orbital energy-level schemes for diatomic molecules of the second-period elements

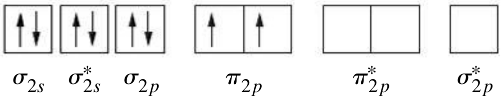
◀ FIGURE 11-26
Molecular orbital occupancy diagrams for the homonuclear diatomic molecules of the second-period elements
In all cases, the σ_{1s} and σ^*_{1s} molecular orbitals are filled but not shown.

described above. For other diatomic molecules of the second-period elements (for example, C_2 and N_2), the π_{2p} orbitals are at a lower energy than σ_{2p} because the energy difference between the 2*s* and 2*p* orbitals is smaller, and 2*s*–2*p* orbital interactions affect the way in which atomic orbitals combine. This leads to the modified σ_{2s} and σ_{2p} orbitals described above.

Here is how we assign electrons to the molecular orbitals of the diatomic molecules of the second-period elements: We start with the σ_{1s} and σ^*_{1s} orbitals filled. Then we add electrons, in order of increasing energy, to the available molecular orbitals of the second principal shell. Figure 11-26 shows the electron assignments for the homonuclear diatomic molecules of the second-period elements. Some molecular properties are also listed in the figure.

Just as we might arrange the valence-shell atomic orbitals of an atom, we can arrange the second-shell molecular orbitals of a diatomic molecule in the order of increasing energy. Then we can assign electrons to these orbitals, thereby obtaining a *molecular orbital diagram.* If we assign the eight valence electrons of the molecule C_2 to the diagram in Figure 11-25(a), we obtain



σ_{2s}
σ^*_{2s}
σ_{2p}
π_{2p}
π^*_{2p}
σ^*_{2p}

Experiment shows that the C_2 molecule is diamagnetic, not paramagnetic, and the configuration just described is *incorrect*. So here we see the importance

◀ A *homonuclear* diatomic molecule (X_2) is one in which both atoms are of the same kind. A *heteronuclear* diatomic molecule (XY) is one in which the two atoms are different.

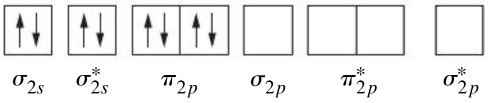
KEEP IN MIND

that Hund's rule applies to molecules as well as atoms.

▶ Just as we wrote an orbital diagram for an atom and a diatomic molecule, we can also write electron configurations for an atom and a diatomic molecule. Thus, for the ground state of C_2, we have (omitting the σ orbitals formed by the $1s$ orbitals) $\sigma_{2s}^2\sigma_{2s}^{*2}\pi_{2p}^4$.

▶ Instead of writing the molecular orbital diagram, we can write the ground state configuration of O_2 as $\sigma_{2s}^2\sigma_{2s}^{*2}\sigma_{2p}^2\pi_{2p}^4\pi_{2p}^{*2}$. When writing the electron configuration for a molecule, we follow the convention we used when writing the electron configuration for an atom. That is, we write the orbital designation by placing the number of electrons as a superscript.

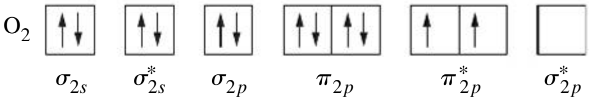
of the modified energy-level diagram in Figure 11-25(b). Assignment of eight electrons to the following molecular orbital diagram is consistent with the observation that C_2 is diamagnetic.



This modified energy-level diagram is used for homonuclear diatomic molecules involving elements with atomic numbers from three through seven.

A Special Look at O_2

Molecular orbital theory helps us understand some of the previously unexplained features of the O_2 molecule. Each O atom brings six valence electrons to the diatomic molecule, O_2. In the molecular orbital diagram below, we see that when 12 valence electrons are assigned to molecular orbitals, the molecule has *two unpaired electrons*. This explains the paramagnetism of O_2 (see page 401).



(11.2)

There are eight valence electrons in bonding orbitals and four in antibonding orbitals so the bond order is two. A bond order of two corresponds to a covalent double bond.

EXAMPLE 11-6 Writing a Molecular Orbital Diagram and Determining Bond Order

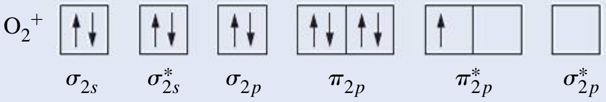
Represent bonding in O_2^+ with a molecular orbital diagram, and determine the bond order in this ion.

Analyze

The O_2^+ ion has 11 valence electrons. We can assign these to the available molecular orbitals in accordance with the ideas stated on page 466. Alternatively, we can remove one electron from an orbital in the molecular orbital diagram given in equation (11.2).

Solve

In the following diagram, there is an excess of *five* bonding electrons over antibonding ones. The bond order is 2.5.



Assess

The electronic configuration of O_2^+ is $\sigma_{2s}^2\sigma_{2s}^{*2}\sigma_{2p}^2\pi_{2p}^4\pi_{2p}^{*1}$. Note that in this diatomic molecule, the molecular orbital diagram without $2s$–$2p$ mixing is used, because the $2s$–$2p$ separation in oxygen is large.

PRACTICE EXAMPLE A: Refer to Figure 11-26. Write a molecular orbital diagram, determine the bond order, and write the electronic configurations of **(a)** N_2^+; **(b)** Ne_2^+; **(c)** C_2^{2-}.

PRACTICE EXAMPLE B: The bond lengths for O_2^+, O_2, O_2^-, and O_2^{2-} are 112, 121, 128, and 149 pm, respectively. Are these bond lengths consistent with the bond order determined from the molecular orbital diagram? Explain.

11-6 CONCEPT ASSESSMENT

In valence bond theory, π bonds are always accompanied by a σ bond. Can the same also be said of the molecular orbital theory for diatomic molecules?

A Look at Heteronuclear Diatomic Molecules

The ideas that we have developed for homonuclear diatomic species can be extended, with some care, to give us an idea of the bonding in heteronuclear diatomic species. To illustrate how to construct a molecular orbital diagram for a heteronuclear diatomic molecule, let us consider the molecule carbon monoxide, CO. The first task is to decide whether or not there is $2s$–$2p$ mixing, based on our knowledge of how Z_{eff} varies across the period. The Z_{eff} of carbon is much lower than that of oxygen, and so the $2s$ and $2p$ orbitals of carbon are higher in energy than those of oxygen. This means that the contributions by each atom to the molecular orbitals will be unequal (we will discuss this in more detail later). In addition, the $2s$–$2p$ separation in carbon is much lower than in oxygen, and so we expect $2s$–$2p$ mixing to occur in the σ orbitals.

The molecular orbitals for CO are shown in Figure 11-27. As a result of $2s$ and $2p$ orbital mixing, the third σ orbital, 3σ, has an orbital energy greater than that of the π_{2p} orbitals, and therefore the *highest occupied molecular orbital* (HOMO) is 3σ. Figure 11-27 does not show the individual contributions made by the carbon and oxygen atomic orbitals to the 3σ or other σ orbitals. To visualize the σ molecular orbitals, we must use the results of quantum mechanical calculations. The results of such calculations are shown in Figure 11-27. Two interesting features are evident. First, the HOMO (3σ) is dominated by the oxygen $2s$ orbital and is essentially nonbonding. Second, the 1σ orbital is dominated by the oxygen $2s$ orbital and is also essentially nonbonding. A *nonbonding molecular orbital* has the same energy as the atomic orbitals from which it is formed, and it neither adds to nor detracts from bond formation. The bonding in CO comes from two electrons in the 2σ orbital and two electron pairs in the degenerate 1π orbitals, producing an effective bond order of 3. The configuration of CO (ignoring the $1s$ orbitals) can therefore be written as follows:

$$1\sigma^2 2\sigma^2 1\pi^4 3\sigma^2$$

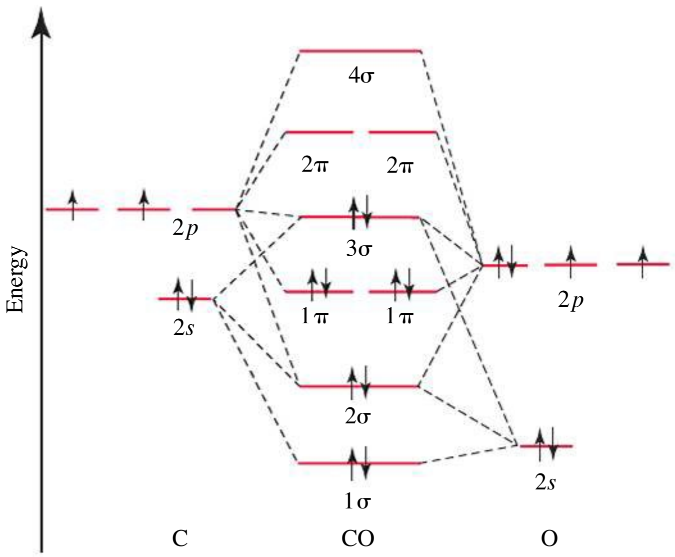
where, as indicated above, we have lost the designations, such as σ_{2s}, through $2s$ and $2p$ mixing. As an approximation, we can pretend we still have these designations and write the configuration as follows:

$$\sigma_{2s}^2 \sigma_{2s}^{*2} 1\pi^4 \sigma_{2p}^2$$

This still gives a bond order of 3, but the source of chemical bonding is misassigned. Bearing this in mind, we can still use this approach to estimate bond orders. When we consider the free radical NO, the extra electron is in the 2π orbital; thus, the configuration is

$$1\sigma^2 2\sigma^2 1\pi^4 3\sigma^2 2\pi^1$$

◀ For a discussion of the orbital structure of CO, see the Focus On feature for Chapter 11, Photoelectron Spectroscopy on the MasteringChemistry website, www.masteringchemistry.com.



◀ FIGURE 11-27
The molecular orbital diagram of CO
Notice that the CO molecular orbitals are ordered in the same manner as the molecular orbitals in Figure 11-25(b). The σ orbitals for CO are labeled 1σ, 2σ, 3σ, and 4σ, because these orbitals are mixtures of $2s$ and $2p$ orbitals from both C and O.

The bond order becomes 2.5. We expect the bond energy in NO to be less than in CO, as is observed experimentally.

EXAMPLE 11-7 Writing Electron Configurations for Heteronuclear Diatomic Species

Write the molecular orbital for the cyanide ion, CN^-, and determine the bond order for this ion.

Analyze

The ion CN^- is isoelectronic with CO. Both elements have a low $2s$–$2p$ gap so that we expect $2s$–$2p$ mixing. The 3σ orbital is higher in energy than the 1π orbitals.

Solve

The number of valence electrons to be assigned to the molecular orbitals is $10(4 + 5 + 1)$. Because of the $2s$–$2p$ mixing, we use the modified order of molecular orbitals and write the configuration of CN^- as

$$1\sigma^2 2\sigma^2 1\pi^4 3\sigma^2$$

Or, as an approximation,

$$\sigma_{2s}^2 \sigma_{2s}^{*2} 1\pi^4 \sigma_{2p}^2$$

which gives a bond order of $(2 + 4 + 2 - 2)/2 = 3$.

Assess

As expected the bond order in CN^- is 3, as it is in the isoelectronic molecule CO. In addition the Lewis structure also gives a triple bond.

PRACTICE EXAMPLE A: Write the electron configuration for CN^+, and determine the bond order.

PRACTICE EXAMPLE B: Write the electron configuration for BN, and determine the bond order.

11-7 CONCEPT ASSESSMENT

Would you expect NeO to be a stable molecule?

▶ The term *aromatic* relates to the fragrant aromas associated with some (but by no means all) of these compounds.

11-6 Delocalized Electrons: Bonding in the Benzene Molecule

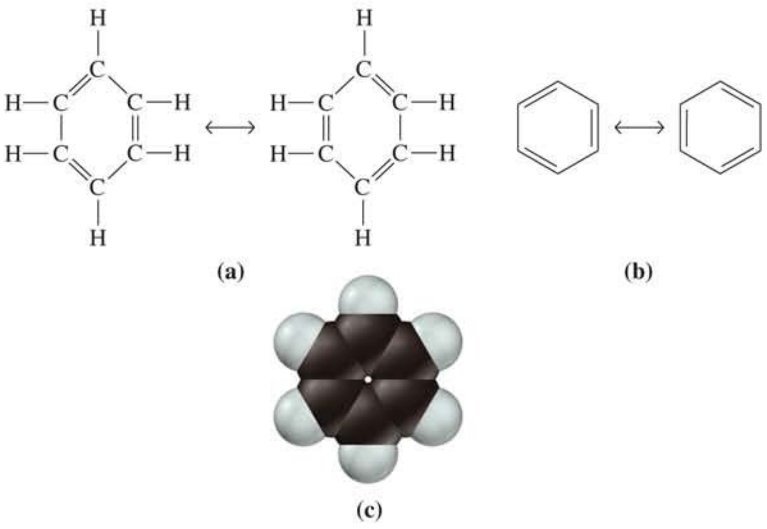
In Section 11-4 we discussed localized π bonds, such as those in ethylene, C_2H_4. Some molecules, such as benzene (C_6H_6) and substances related to it—aromatic compounds—have a network of π bonds. In this section we will use the bonding theories we have studied thus far to consider bonding in benzene; the conclusions we reach will help us understand other cases of bonding as well.

▲ Dame Kathleen Lonsdale first determined the X-ray crystal structure of benzene. Her experiment demonstrated that the benzene molecule is flat, as predicted by theorists.

Bonding in Benzene

In 1865, Friedrich Kekulé advanced the first good proposal for the structure of benzene. He suggested that the C_6H_6 molecule consists of a flat, hexagonal ring of six carbon atoms joined by alternating single and double covalent bonds. Each C atom is joined to two other C atoms and to one H atom. To explain the fact that the carbon-to-carbon bonds are all alike, Kekulé suggested that the single and double bonds continually oscillate from one position to the other. Today, we say that the two possible Kekulé structures are actually contributing structures to a resonance hybrid. This view is suggested by Figure 11-28.

We can gain a more thorough understanding of bonding in the benzene molecule by combining the valence-bond and molecular orbital methods. A σ-bond framework for the observed planar structure can be constructed with 120° bond angles by using sp^2 hybridization at each carbon atom. End-to-end overlap of the sp^2 orbitals produces σ bonds. The six remaining $2p$ orbitals are



◀ FIGURE 11-28
Resonance in the benzene molecule and the Kekulé structures
(a) Lewis structure for C_6H_6 showing alternate carbon-to-carbon single and double bonds. **(b)** Two equivalent Kekulé structures for benzene. A carbon atom is at each corner of the hexagonal structure, and a hydrogen atom is bonded to each carbon atom. (The symbols for carbon and hydrogen, as well as the C—H bonds, are customarily omitted in these structures.) **(c)** A space-filling model.

used to construct the delocalized π bonds. Figure 11-29 gives a valence-bond theory representation of bonding in C_6H_6.

We do not need to think in terms of an oscillation between two structures (Kekulé) or of a resonance hybrid for benzene. The π bonds are not localized between specific carbon atoms but are spread out around the six-membered ring. To represent this *delocalized* π bonding, the symbol for benzene is often written as a hexagon with an inscribed circle (Fig. 11-29c).

We can best understand delocalized π bonds through molecular orbital theory. Six $2p$ atomic orbitals (see Figure 11-29b) of the C atoms combine to form six molecular orbitals of the π type. Three of these π-type molecular orbitals are bonding, and three are antibonding. What do these π molecular orbitals look like? Recall that as the energy of orbitals increases, the number of nodes increases, so we expect that the lowest π molecular orbital will not possess a node, and this is the case (Fig. 11-30a). All six $2p$ orbitals are in phase as indicated by the fact that all the blue lobes are on one side of the σ framework. The next two π-bonding molecular orbitals each have one node (dashed line in Figure 11-30a) and consequently have the same energy; that is, they are degenerate (Fig. 11-30b). The next pair of orbitals, which are antibonding π orbitals, have two nodes, and the final orbital has three nodes (Fig. 11-30a). The computed π molecular orbitals of benzene are also included in Figure 11-30(c).

The three bonding orbitals fill with six electrons (one $2p$ electron from each C atom), and the three antibonding orbitals remain empty. The bond order associated with the six electrons in π-bonding molecular orbitals is $(6 - 0)/2 = 3$. The three bonds are distributed among the six C atoms, which amounts to 3/6, or a half-bond, between each pair of C atoms. Add to this the σ bonds in the σ-bond framework, and we have a bond order of 1.5 for each carbon-to-carbon bond. This is exactly what we also get by averaging the two Kekulé structures of Figure 11-28.

▼ FIGURE 11-29
Bonding in benzene, C_6H_6, by the valence-bond method
(a) Carbon atoms use sp^2 and p orbitals. Each carbon atom forms three σ bonds, two with neighboring C atoms in the hexagonal ring and a third with a H atom. **(b)** The unhybridized $2p$ orbitals on the carbon atoms of benzene, which produce the delocalized π bonds in benzene. **(c)** Because the π bonding is delocalized around the benzene ring, the molecule is often represented by a hexagon with an inscribed circle.

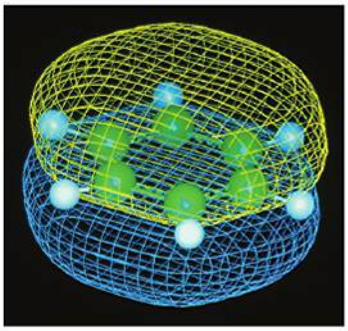
π molecular orbital diagram for C_6H_6
Of the six π molecular orbitals, three are bonding orbitals and each of these is filled with an electron pair. The three antibonding molecular orbitals at higher energy remain empty.

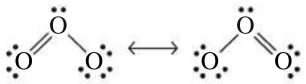


▲ FIGURE 11-31
Molecular orbital representation of π bonding in benzene
The computed π molecular orbitals of benzene.

The three bonding π molecular orbitals in C_6H_6 describe the distribution of π electron charge in the molecule. We can think of this in terms of two doughnut-shaped regions: one above and one below the plane of the C and H atoms. Because they are spread out among all six C atoms instead of being concentrated between pairs of C atoms, these molecular orbitals are called **delocalized molecular orbitals**. Figure 11-31 pictures these delocalized molecular orbitals in the benzene molecule. The electrostatic potential maps of benzene displayed at the opening of this chapter also show the buildup of negative charge density above and below the plane of the benzene molecule.

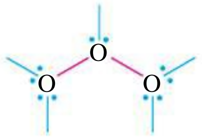
Other Structures with Delocalized Molecular Orbitals

By using delocalized bonding schemes, we can avoid writing two or more contributing structures to a resonance hybrid, as is so often required in the Lewis theory. Consider the ozone molecule, O_3, that we used to introduce the concept of resonance in Section 10-5. In place of the resonance hybrid based on these contributing structures,

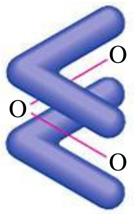


we can write the single structure shown in Figure 11-32. Here are the ideas that lead to Figure 11-32.

1. With VSEPR theory, we predict a trigonal-planar electron-group geometry (the measured bond angle is 117°). The hybridization scheme chosen for the central O atom is sp^2, and although we normally do not need to invoke hybridization for terminal atoms, this case is simplified if we assume sp^2 hybridization for the terminal O atoms as well. Thus, each O atom uses the orbital set $sp^2 + p$.
2. Of the 18 valence electrons in O_3, assign 14 to the sp^2 hybrid orbitals of the σ-bond framework. Four of these are bonding electrons (red) and ten are lone-pair electrons (blue).

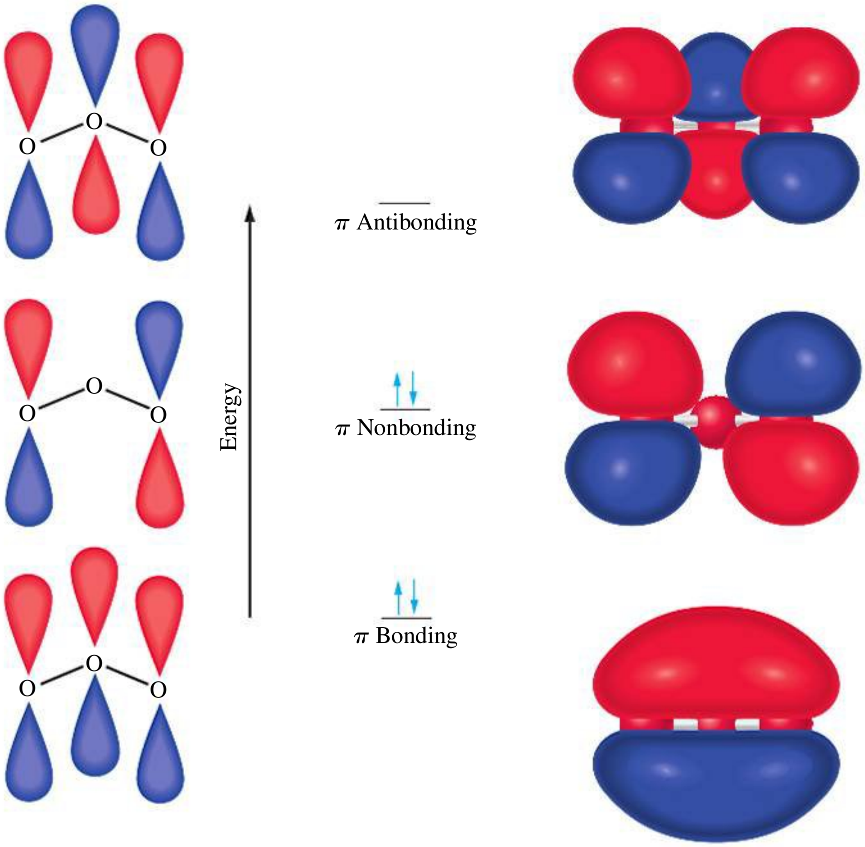


(a) σ bond framework



(b) Delocalized π molecular orbital

▲ FIGURE 11-32
Structure of the ozone molecule, O_3
(a) The σ-bond framework and the assignment of bond-pair (|) and lone-pair (:) electrons to sp^2 hybrid orbitals are discussed in points 1 and 2. **(b)** The π molecular orbitals and assignments of electrons to them are discussed in points 3 and 4.



◀ FIGURE 11-33
π bonding orbitals of the ozone molecule O_3
The π-bonding molecular orbital has all the 2*p* orbitals in phase. The π-antibonding molecular orbital has all the three 2*p* orbitals out of phase. The π-nonbonding molecular orbital has a single node and makes zero contribution to the wave function from the central atom. This orbital is called *nonbonding* because there is no region of increased electron density between the central atom and its neighbors. The nonbonding orbital is at the same energy as the original 2*p* orbitals on the oxygen atoms, whereas the π-bonding molecular orbital is stabilized with respect to the original orbitals and the π-antibonding molecular orbital is destabilized by an equal amount with respect to the original 2*p* orbitals. The energy level diagram is shown in the middle of this figure, with the computed π molecular orbitals shown on the right.

3. The three unhybridized 2*p* orbitals combine to form *three* molecular orbitals of the π type (Fig. 11-33). One of these orbitals is a bonding molecular orbital, and the second is antibonding. The third is a type we described on page 473—a *nonbonding molecular orbital*. A nonbonding molecular orbital has the same energy as the atomic orbitals from which it is formed, and it neither adds to nor detracts from bond formation.
4. The remaining four valence electrons are assigned to the π molecular orbitals. Two go into the bonding orbital and two into the nonbonding orbital. The antibonding orbital remains empty.
5. The bond order associated with the π molecular orbitals is $(2 - 0)/2 = 1$. This π bond is distributed between the two O—O bonds and amounts to one-half of a π bond for each.

The points listed here lead to a total bond order of 1.5 for the O—O bonds in O_3. This is equivalent to averaging the two Lewis structures. The O—O bond length suggested by this method was described in Section 10-5.

EXAMPLE 11-8 Representing Delocalized Molecular Orbitals with Atomic Orbital Diagrams

Represent π molecular orbital formation, bonding, and orbital occupancy in the nitrate ion, NO_3^-.

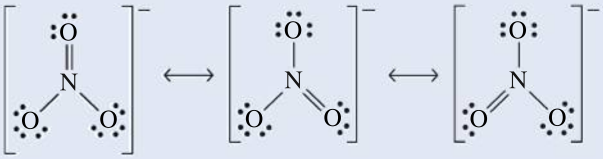
Analyze

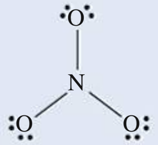
We proceed in the manner described on page 476. First, we focus on electrons associated with the σ-bond framework and determine hybridization schemes for the atoms. Then, we determine the number of electrons in the π system, and the number of 2*p* orbitals involved forming the π molecular orbitals. The key to solving this problem is reasoning out the number of each type of molecular orbital (bonding, antibonding, nonbonding) in the π system. The final step is to assign electrons in the π system to the appropriate molecular orbitals.

(continued)

Solve

The total number of electrons in the NO_3^- ion is $(3 \times 6 + 5 + 1) = 24$. Resonance structures for the NO_3^- ion and the corresponding σ bond framework are shown below. Because the N atom is bonded to three atoms, it is sp^2-hybridized. Each O atom may also be considered to be sp^2-hybridized, with one of its sp^2 hybrid orbitals used to form a σ bond with N and other two accommodating the lone pairs.

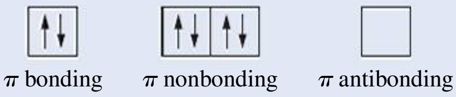


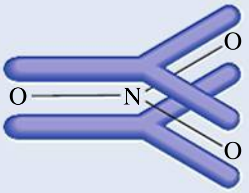


sp^2 σ framework

The number of electrons in the σ bond framework is 18, and so the number of electrons in the π system is $24 - 18 = 6$. These 6 electrons must be assigned to π molecular orbitals obtained from combining four $2p$ orbitals (one on each atom). We must now reason out the number and types of molecular orbitals there are in the π system.

Starting from four $2p$ orbitals, we must obtain a total of four π molecular orbitals. As was the case for ozone, one of the molecular orbitals is a bonding orbital (all the $2p$ orbitals in phase) and another is an antibonding orbital (all the $2p$ orbitals out of phase). The π-bonding orbital is lower in energy and the π-antibonding orbital is higher in energy than the $2p$ orbitals. Thus, there must be $4 - 2 = 2$ *nonbonding* molecular orbitals in the π system. These nonbonding orbitals are equal in energy to the $2p$ orbitals, and thus higher in energy than the bonding molecular orbital but lower in energy than the antibonding molecular orbital. The molecular orbital diagram below illustrates how the six π electrons are assigned to the π molecular orbitals.





Delocalized π molecular orbitals of NO_3^-

Thus, the overall π bond order in the NO_3^- ion is one.

Assess

The overall π bond order for this ion is one, and as suggested by the diagram above, the π bond is spread equally over three nitrogen-oxygen bonds. Are You Wondering 11-4 provides schematic representations of the π molecular orbitals of NO_3^-.

PRACTICE EXAMPLE A: Represent chemical bonding in the molecule SO_3 by using a combination of localized and delocalized orbitals.

PRACTICE EXAMPLE B: Represent chemical bonding in the ion NO_2^- by using a combination of localized and delocalized orbitals.

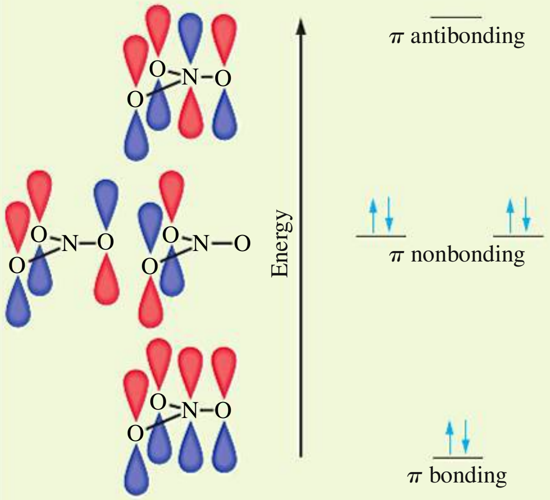
11-8 CONCEPT ASSESSMENT

Would you expect the delocalized π-bonding framework in HCO_2^- to be similar to that in ozone or to that in the nitrate anion?

11-4 ARE YOU WONDERING...

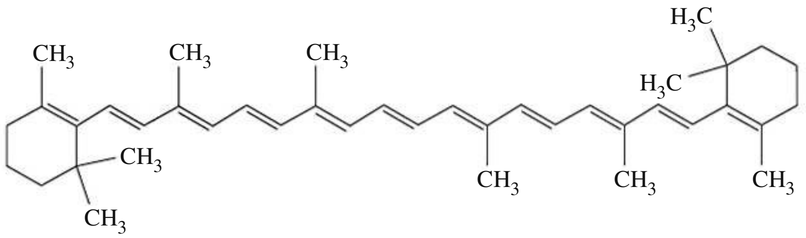
What the π molecular orbitals of NO_3^- look like?

The construction of these orbitals is shown in Figure 11-34. The π-bonding molecular orbital has the four $2p$ orbitals (one on the N atom and one each on the three oxygen atoms) all in phase. The corresponding antibonding π orbital has two nodes and is at the highest energy. Since we are combining four 2*p* orbitals we expect to get four molecular orbitals. The remaining two molecular orbitals will each have one node. The only way to create a molecular orbital with one node in NO_3^- is for the molecular orbital to have a node at the nitrogen atom. Such a molecular orbital must be nonbonding with respect to nitrogen. That the nitrogen does not contribute to the degenerate nonbonding orbitals can be clearly seen in the computed molecular orbitals depicted in Figure 11-34.



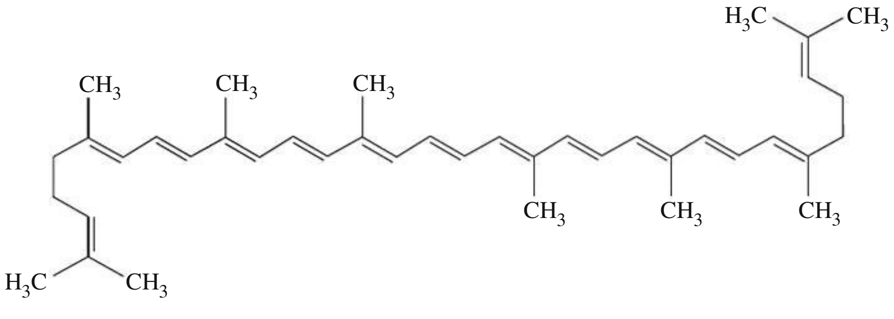
▲ FIGURE 11-34 **π bonding orbitals of the nitrate anion, NO_3^-**
The π-bonding molecular orbital has all the *p* orbitals in phase, whereas the π-antibonding orbital has all the *p* orbitals out of phase. Each of the nonbonding orbitals has a node at the nitrogen atom.

To illustrate the importance of molecular orbital theory, we will see how it is used to explain the colors of plants. Two pigment molecules typically isolated from vegetables are β-carotene



β-Carotene, $C_{40}H_{56}$

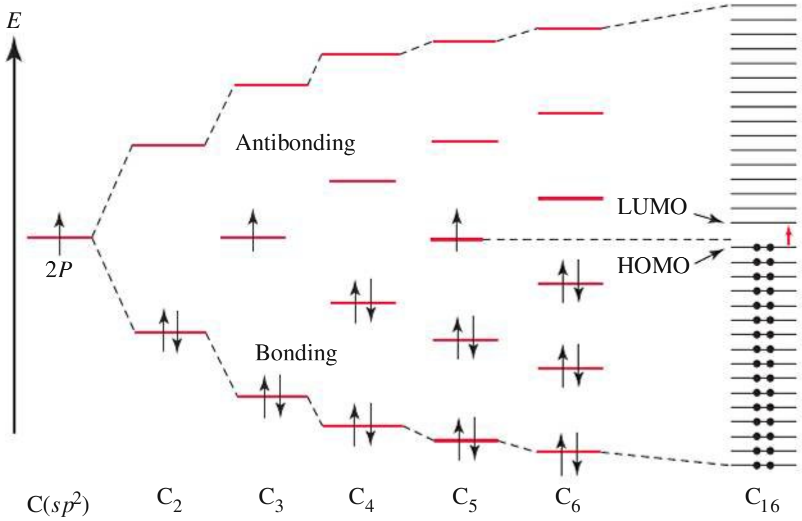
found in carrots and leaves, and lycopene



Lycopene, $C_{40}H_{58}$

which is present in tomatoes. The common feature of these molecules is the extended π system. The many *p* orbitals on the trigonal-planar carbon atoms contribute to many π molecular orbitals. As a consequence, the molecules have many π molecular energy levels that become very closely spaced (see Fig. 11-35).

In molecules with long extended π systems, the *highest occupied molecular orbital* (HOMO) is very close in energy to the *lowest unoccupied molecular orbital*



▲ FIGURE 11-35
The formation of π molecular orbitals in a long-chain polyene
The formation of such an extended π system requires an alternation of double and single bonds, as occurs in such molecules as carotene. There are many closely spaced energy levels, and the HOMO–LUMO gap is quite small. Molecules with such an extended π system are often colored because photons of visible light can excite electrons from the HOMO to the LUMO.

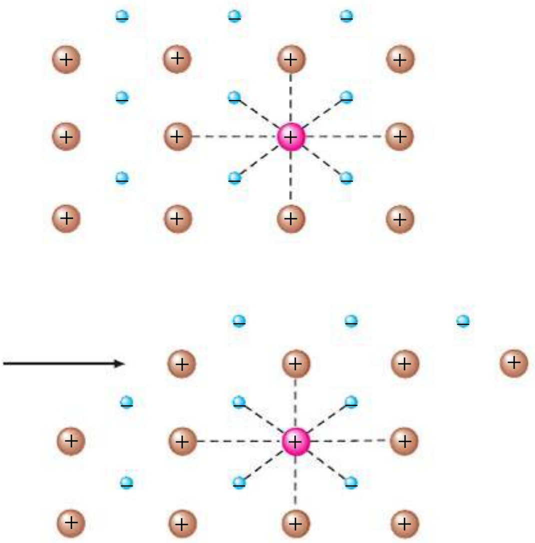
(LUMO). As a result it takes very little energy to excite an electron from the HOMO to the LUMO (Fig. 11-35). Photons of visible light have enough energy to excite the electrons across the energy gap between the HOMO and the LUMO, and the absorption of these photons is responsible for the colors that we see.

11-7 Bonding in Metals

In nonmetal atoms, the valence shells generally have more electrons than they do orbitals. To illustrate, a F atom has *four* valence-shell orbitals ($2s$, $2p_x$, $2p_y$, $2p_z$) and *seven* valence-shell electrons. Whether fluorine exists as a solid, liquid, or gas, F atoms join in pairs to form F_2 molecules. One pair of electrons is shared in the F—F bond, and the other electron pairs are lone pairs, as seen in the Lewis structure :F̤̈—F̤̈:. By contrast, the metal atom Li has the same four valence-shell orbitals as F but only *one* valence-shell electron ($2s^1$). This may account for the formation of the *gaseous* molecule Li:Li, but in the solid metal, each Li atom is somehow bonded to *eight* neighbors. The challenge to a bonding theory for metals is to explain how so much bonding can occur with so few electrons. Also, the theory should account for certain properties that metals display to a far greater extent than nonmetals—such as a lustrous appearance, an ability to conduct electricity, and ease of deformation (metals are easily flattened into sheets and drawn into wires).

The Electron Sea Model

An oversimplified theory, which can explain some of the properties of metals just cited, pictures a solid metal as a network of positive ions immersed in a "sea of electrons." In lithium, for instance, the ions are Li^+ and one electron per atom is contributed to the sea of electrons. Electrons in the sea are *free* (not attached to any particular ion), and they are mobile. Thus, if electrons from an external source enter a metal wire at one end, free electrons pass through the wire and leave the other end at the same rate. In this way, electrical conductivity is explained.



◀ FIGURE 11-36
The electron sea model of metals
A network of positive ions is immersed in a "sea of electrons," derived from the valence shells of the metal atoms and belonging to the crystal as a whole. One particular ion (red), its nearest neighboring ions (brown), and nearby electrons in the electron sea (blue) are emphasized. At the bottom of the figure, a force is applied (from left to right). The highlighted cation is unaffected; its immediate environment is unchanged. The electron sea model explains the ease of deformation of metals.

Free electrons (those in the electron sea) are not limited in their ability to absorb photons of visible light as are electrons bound to an atom. Thus, metals absorb visible light; they are opaque. Electrons at the surface of a metal are able to reradiate—at the same frequency—light that strikes the surface, which explains the lustrous appearance of metals. The ease of deformation of metals can be explained as follows: If one layer of metal ions is forced across another, perhaps by hammering, no bonds are broken, the internal structure of the metal remains essentially unchanged, and the sea of electrons rapidly adjusts to the new situation (Fig. 11-36).

◀ A dull metal surface usually signifies that the surface is coated with a compound of the metal (for example, an oxide, a sulfide, or a carbonate).

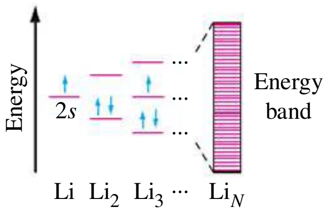
Band Theory

The electron-sea model is a simple qualitative description of the metallic state, but for most purposes, the theory of metallic bonding used is a form of molecular orbital theory called **band theory**.

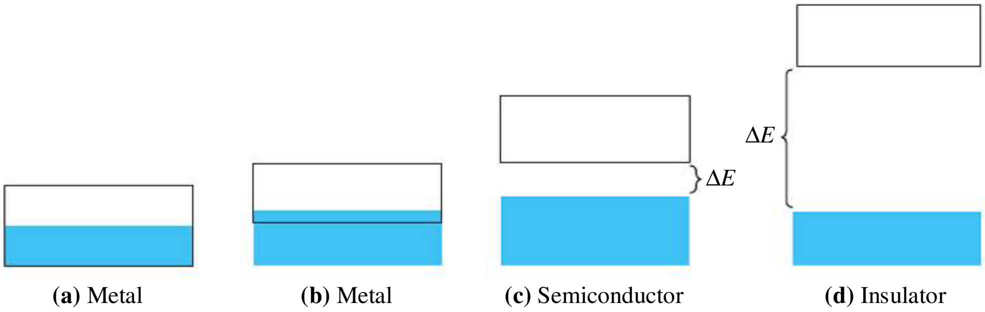
◀ Even though bands are formed in metals, the electrons still have to fill according to Pauli's exclusion principle.

Recall the formation of molecular orbitals and the bonding between two Li atoms (see Figure 11-26). Each Li atom contributes one 2*s* orbital to the production of two molecular orbitals: σ_{2s} and σ^*_{2s}. The electrons originally described as the $2s^1$ electrons of the Li atoms enter and half-fill these molecular orbitals. That is, they fill the σ_{2s} orbital and leave the σ^*_{2s} empty. If we extend this combination of Li atoms to a third Li atom, three molecular orbitals are formed, containing a total of three electrons. Again, the set of molecular orbitals is half-filled. We can extend this process to an enormously large number (N) of atoms—the total number of atoms in a crystal of Li. Here is the result we get: a set of N molecular orbitals with an extremely small energy separation between each pair of successive levels. This collection of very closely spaced molecular orbital energy levels is called an *energy band* (Fig. 11-37).

In the band just described, there are N electrons (a 2*s* electron from each Li atom) occupying, in pairs, $N/2$ molecular orbitals of lowest energy. These are the electrons responsible for bonding the Li atoms together. They are valence electrons, and the band in which they are found is called a *valence band*. Because the energy differences between the occupied and unoccupied levels in the valence band are so small, however, electrons can be easily excited from the highest filled levels to the unfilled levels that lie immediately above them in energy. This excitation, which has the effect of producing mobile electrons, can be accomplished by applying a small electric potential difference across the crystal. This is how the band theory explains the ability of metals to conduct electricity. The essential feature for electrical conductivity, then, is *an energy band that is only partly filled with electrons*. Such an energy band is called a *conduction band*. In lithium, the 2*s* band is both a valence band and a conduction band (Fig. 11-38a).



▲ FIGURE 11-37
Formation of an energy band in lithium metal
As more and more Li atoms are added to the growing "molecule," Li_2, Li_3, and so on, additional energy levels are added and the spacing between levels becomes increasingly smaller. In an entire crystal of N atoms, the energy levels merge into a band of N closely spaced levels. The lowest $N/2$ levels are filled with electrons, and the upper $N/2$ levels are empty.



(a) Metal (b) Metal (c) Semiconductor (d) Insulator

▲ FIGURE 11-38
Metals, semiconductors, and insulators as viewed by band theory
(a) In some metals, the valence band (blue) is only partially filled (for example, the half-filled 3*s* band in Na). The valence band also serves as a conduction band (outlined in black). **(b)** In other metals, the valence band is full, but a conduction band overlaps it (for example, the empty 2*p* band of Be overlaps the full 2*s* valence band). **(c)** In a semiconductor, the valence band is full and the conduction band is empty. The energy gap (ΔE) between the two is small enough, however, that some electrons make the transition between them just by acquiring thermal energy. **(d)** In an insulator, the valence band is filled with electrons and a large energy gap (ΔE) separates the valence band from the conduction band. Few electrons can make the transition between bands, and the insulator does not conduct electricity.

Let's extend our discussion to N atoms of beryllium, which has the electron configuration $1s^2 2s^2$. We expect the band formed from 2*s* atomic orbitals to be filled—N molecular orbitals and $2N$ electrons. But how can we reconcile this with the fact that Be is a good electric conductor? At the same time that 2*s* orbitals are being combined into a 2*s* band, 2*p* orbitals combine to form an *empty* 2*p* band. The lowest levels of the 2*p* band are at a *lower* energy than the highest levels of the 2*s* band. The bands overlap (Fig. 11-38b). As a consequence, empty molecular orbitals are available to the valence electrons in beryllium.

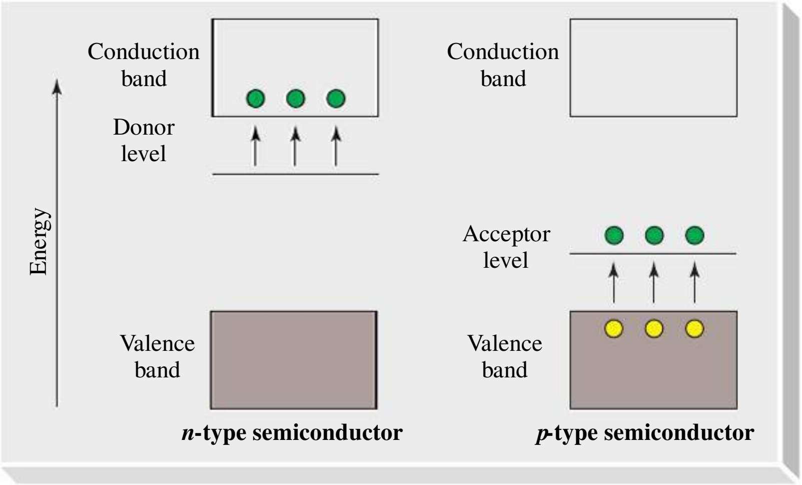
In an *electrical insulator*, like diamond or silica (SiO_2), not only is the valence band filled but there is a large energy gap between the valence band and the conduction band (Fig. 11-38d). Very few electrons are able to make the transition between the two.

Semiconductors

Much of modern electronics depends on the use of semiconductor materials. Light-emitting diodes (LEDs), transistors, and solar cells are among the familiar electronic components that use semiconductors. Such semiconductors as cadmium yellow (CdS) and vermilion (HgS) are brilliantly colored, and artists use them in paints.

What determines the electronic properties of a semiconductor is the energy gap (band gap) between the valence band and the conduction band (Fig. 11-38c). In some materials, such as CdS, this gap is of a fixed size. These materials are called *intrinsic semiconductors*. When white light interacts with the semiconductor, electrons are excited (promoted) to the conduction band. CdS absorbs violet light and some blue light, but other frequencies contain less energy than is needed to excite an electron above the energy gap. The frequencies that are not absorbed are reflected, and the color we see is yellow. Some semiconductors, such as GaAs and PbS, have a sufficiently small band gap that all frequencies of visible light are absorbed. There is no reflected visible light, and the materials have a black color.

In a semiconductor, such as silicon or germanium, the filled valence band and empty conduction band are separated by only a small energy gap. Electrons in the valence band may acquire enough thermal energy to jump to a level in the conduction band. The greater the thermal energy, the more electrons can make



◀ FIGURE 11-39
***p*- and *n*-type semiconductors**
In a semiconductor with donor atoms (for example, P in Si), the donor level lies just beneath the conduction band. Electrons (🟢) are easily promoted into the conduction band. The semiconductor is of the *n*-type. In a semiconductor with acceptor atoms (for example, Al in Si), the acceptor level lies just above the valence band. Electrons (🟢) are easily promoted to the acceptor level, leaving positive holes (🟡) in the valence band. The semiconductor is of the *p*-type.

the transition. In this way, band theory explains the observation that the electrical conductivity of semiconductors increases with temperature.

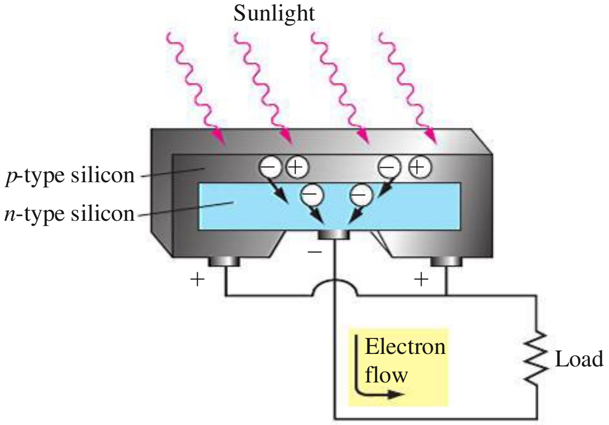
In many semiconductors, called *extrinsic semiconductors*, the size of the band gap is controlled by carefully adding impurities—a process called *doping*. Let's consider what doping does to one of the most common semiconductors, silicon.

◀ A natural semiconductor is called an intrinsic semiconductor. Semimetals that become semiconductors because of doping are called extrinsic semiconductors.

When silicon is doped with phosphorus, the energy level of the P atoms lies just below the conduction band of the silicon, as shown in Figure 11-39. Each P atom uses *four* of its five valence electrons to form bonds to four neighboring Si atoms, and thermal energy alone is enough to cause the "extra" valence electron to be promoted to the conduction band, leaving behind an immobile positive P^+ ion. The P atoms are called *donor* atoms, and electrical conductivity in this type of semiconductor involves primarily the movement of electrons from donor atoms through the conduction band. This type of semiconductor is called an *n-type*, where *n* refers to negative—the type of electric charge carried by electrons.

When silicon is doped with aluminum, the energy level of the Al atoms, called *acceptor* atoms, lies just above the valence band of the silicon (Fig. 11-39). Because an Al atom has only *three* valence electrons, it forms regular electron-pair bonds with three neighboring Si atoms but only a one-electron bond with a fourth Si atom. An electron is easily promoted from the valence band to an Al atom in the acceptor level, however, forming an immobile negative Al^- ion. When this occurs, a *positive hole* is created in the valence band. Because electrical conductivity in this type of semiconductor consists primarily of the migration of positive holes, it is called a *p-type* semiconductor.

Figure 11-40 suggests how semiconductors are used in photovoltaic (solar) cells. A thin layer of a *p*-type semiconductor is in contact with an *n*-type semiconductor in a region called the *junction*. Normally, migration of electrons and



◀ FIGURE 11-40
A photovoltaic (solar) cell using silicon-based semiconductors

positive holes across the junction is very limited because such a migration would lead to a separation of charge: Positive holes crossing the junction from the *p*-type semiconductor would have to move away from immobile Al^- ions, and electrons crossing from the *n*-type semiconductor would have to move away from immobile P^+ ions.

Now imagine that the *p*-type semiconductor is struck by a beam of light. Electrons in the valence band can absorb energy and be promoted to the conduction band, creating positive holes in the valence band. Conduction electrons, unlike positive holes, can easily cross the junction into the *n*-type semiconductor. This sets up a flow of electrons, an electric current. Electrons can be carried by wires through an external load (lights, electric motors, and so forth) and eventually returned to the *p*-type semiconductor, where they fill positive holes. Further light absorption creates more conduction electrons and positive holes, and the process continues as long as light shines on the solar cell.

11-9 CONCEPT ASSESSMENT

Do you think GaN is a semiconductor?

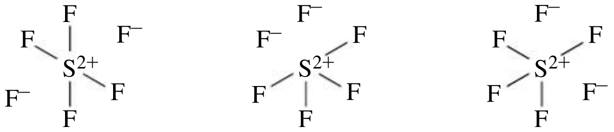
11-8 Some Unresolved Issues: Can Electron Charge-Density Plots Help?

In Chapters 10 and 11 we have presented a wide range of views of chemical bonding, from simple Lewis theory to the more advanced valence-bond and molecular orbital approaches. We must emphasize, however, that each of these models has its deficiencies, and their uncritical use can lead to incorrect conclusions.

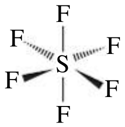
Here are some of the unresolved issues we have encountered: Employing expanded valence shells in Lewis structures created the quandary of where to accommodate the extra valence electrons in such molecules as SF_6 and SF_4 (page 419), specifically, are *d*-orbitals used in the bonding description? A related issue is whether to use expanded valence shells to minimize formal charges in anions such as SO_4^{2-} (page 420). Still another issue is whether VSEPR theory or hybridization schemes of the valence-bond method gives the more fundamental view of molecular shapes. Finally, we might wonder how the valence-bond and molecular orbital theories are related. In this section, we will attempt to provide answers to these questions—stressing the significance of electron charge density calculations.

Bonding in the Molecule SF_6

First let's see if it is possible to describe the bonding in SF_6 while maintaining the octet rule. One proposal has been to introduce resonance structures of the form



with the actual electronic structure being a combination of these resonance structures. The resonance structures illustrate the concept of *hyperconjugation*, a situation in which the number of electron pairs used to bond other atoms to a central atom is less than the number of bonds formed. In the case of SF_6, four electron pairs bond six F atoms to a central S atom and the octet rule is preserved. When resonance structures are written in this way, the assumption is that the bond lines represent nonpolar covalent bonds, whereas the other bonds are fully ionic. The molecule SF_6 has equivalent bonds and consequently would require a total of 15 structures of the type shown. This description implies a charge of 2+ on the sulfur and a charge of 1/3− on each F atom, corresponding to a collective charge of 2− on the six F atoms. This description of bonding, then, has the appeal of describing the polarity of the bonds while getting around the problem that arises when the Lewis structure is written as shown below, namely, where do the "extra" electrons go on the S atom?



Should we use hyperconjugation to describe the bonding in SF_6? One answer is to compare the suggested charges on the S and F atoms with those obtained from a quantum-mechanical calculation. The calculation gives a charge of 3.17+ on sulfur and 0.53− on each fluorine. To describe bonding through hyperconjugation that is in better agreement with the quantum-mechanical calculation, we would have to use additional resonance structures with higher charges and fewer covalent bonds. Such an approach is clearly cumbersome, and adoption of this large number of structures is not justified just to satisfy the octet rule.

The problem in describing molecules with expanded valence shells, so-called *hypervalent* molecules, is that there is no generally accepted way of denoting polar bonds in a structure. Furthermore, we must remember that Lewis devised his "rule of eight" in an era when only a few molecules, such as, PCl_5 and SF_6, were known, and he did not consider these exceptions to be of any great significance. Why was that? Lewis viewed the "rule of two" to be of greater fundamental importance than the rule of eight; that is, the electron charge density caused by the electron pair is paramount in understanding bonding. Bonding in molecules with expanded valence shells is not a consequence of a special type of bonding. Bonds in these molecules are similar to those in other molecules and can vary from predominantly covalent to predominantly ionic.

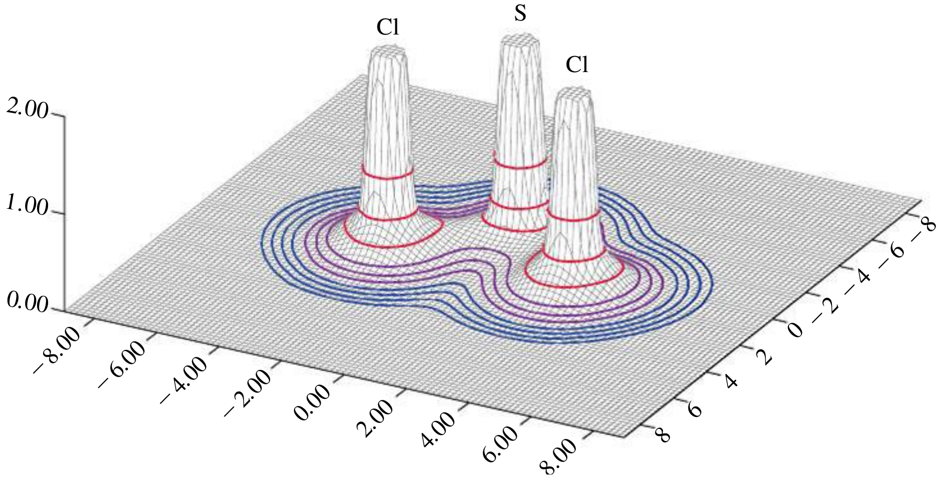
If we do not use hyperconjugation, how are we to describe where the "extra" electrons go? This question arises because we seem implicitly to think about bonding in terms of hybridization of atomic orbitals. Thus, in order to describe bonding in the methane molecule consistent with its tetrahedral geometry we introduced the concept of sp^3 hybrid orbitals. That is, the hybridization was introduced *because* of the geometry. The geometry of a molecule can be determined only experimentally or estimated by using VSEPR theory.

We extended the concept of hybridization of orbitals to molecules with expanded valence shells to include *d* orbitals, that is, sp^3d and sp^3d^2 hybrid orbitals to accommodate five- and six-electron pairs, respectively. Although this is an appealing idea, it has come into question because of the relatively high energy of the *d* orbitals, and quantum-mechanical calculations have shown that the wave functions contain very little contribution from *d* orbitals. Thus, it appears that to describe bonding in SF_6 we should avoid using *d* orbitals in hybridization schemes.

How are we to proceed? Where are the electrons in the SF_6 molecule? Recall that we have already employed the results of quantum-mechanical calculations in constructing electrostatic potential maps (page 402). Let's turn again to the results of such calculations to improve our understanding of the bonding in SF_6 and similar molecules.

Bonding in the Molecule SCl_2

To continue our discussion consider first a simpler molecule—SCl_2. Figure 11-41 shows how the electron charge density (ρ) varies in the plane that contains the sulfur atom and the two chlorine atoms. The most striking feature of this



▲ FIGURE 11-41
Isodensity contour map of the electron density of SCl_2 in the plane of the nuclei
The isodensity contour lines, in atomic units (au), are shown in color, in the order 0.001, 0.002, 0.004, 0.008 (four outermost contours in blue); 0.2, 0.4, 0.8 (next three). Densities are truncated at 2.00 au (innermost red contour). The atomic unit of electron charge density $= e/a_0{}^3 = 1.081 \times 10^{12}$ C m^3, where a_0 is the Bohr radius (adapted from Matta and Gillespie, *J. Chem. Ed.*, 79, 1141, 2002).

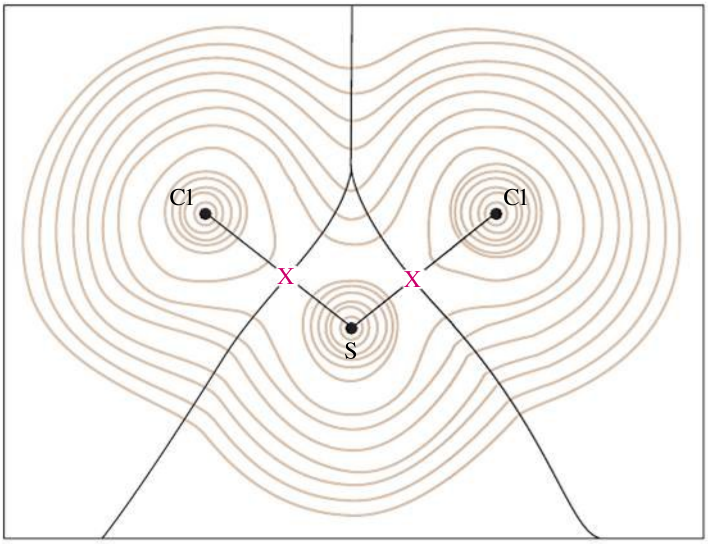
diagram is that the electron density is very high at each nucleus; in fact, we have truncated the very large maxima in order to show other features in the diagram. An especially significant feature is the small ridge of increased electron density between the sulfur and each of the chlorine atoms. Despite its modest height, this ridge of electron density is responsible for an attractive force between the nuclei.

KEEP IN MIND

that a contour map represents changes in topology of a surface; similar maps are used by mountaineers to plan their ascent of a mountain.

An alternative representation of the electron density distribution is a contour map. Such a contour map for SCl_2 is shown in Figure 11-42. The lines drawn between the S atom and each Cl atom in Figure 11-42 represent the lines along the top of the small ridge of electron charge density between these atoms that we saw in Figure 11-41. The lines between the chlorine atoms and the sulfur atom are called the *bond paths* and represent the chemical bond between the S and one Cl atom as we would normally draw it in a Lewis structure. In Figure 11-42, notice the vertical line above the S atom that splits in two just before the sulfur atom is reached, with each segment intersecting the bond paths for the two sulfur-chlorine bonds between the S and a Cl atom. This

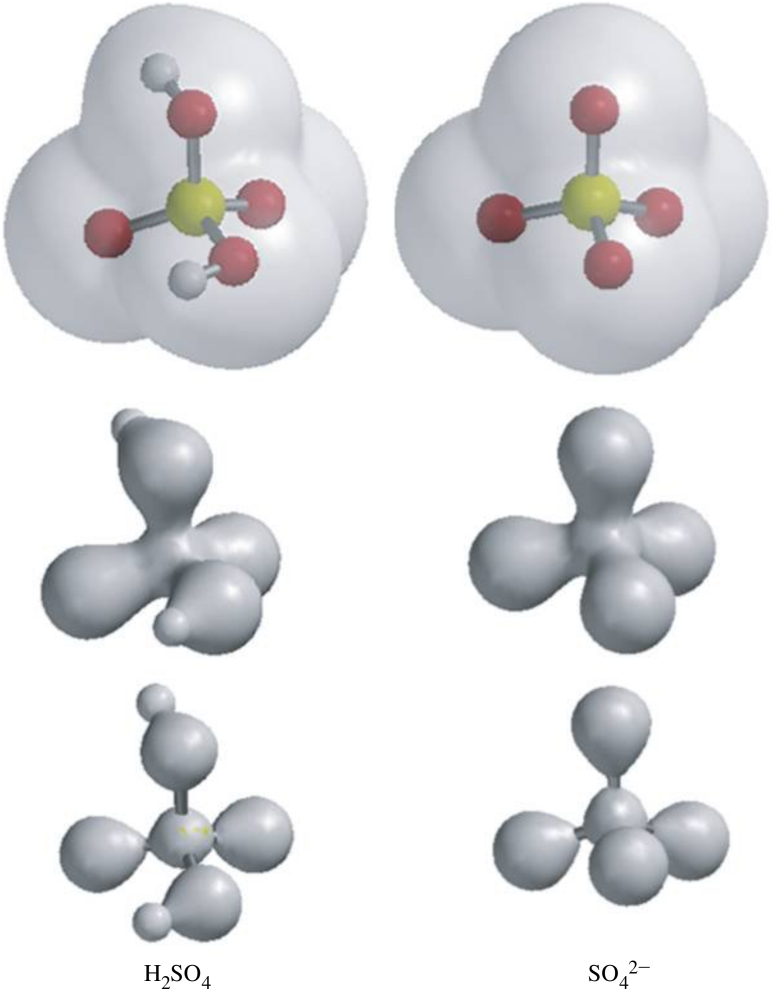
▶ FIGURE 11-42
Contour map of the electron density in SCl_2
The electron charge density increases from the outermost isodensity contour at 0.001 au in incremental steps of 2×10^{-3} au, 4×10^{-2} au, 8×10^{-1} au, 16×10^{0} au, and so on. The lines connecting the nuclei are the bond paths. The bond critical points are depicted by red Xs (adapted from Matta and Gillespie, *J. Chem. Ed.*, 79, 1141, 2002).



bifurcated line represents a path tracing the minimum in the electron density, analogous to a path along the valley floor between the "mountains" of electron density. The point where this line intersects each bond line is called the *bond critical point*. The electron density at the bond critical point can be used to describe the type of bond connecting a pair of atoms in a molecule. The greater the electron density, the higher the bond order is.

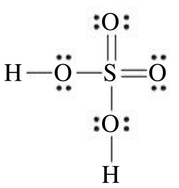
Bonding in the Molecule H_2SO_4 and the Anion $SO_4{}^{2-}$

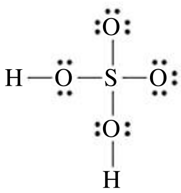
To decide whether or not to use expanded valence shells to minimize formal charges, we will consider the sulfuric acid molecule and the sulfate anion. Figure 11-43 is a three-dimensional representation of the electron charge distribution surfaces at a value of 0.001 atomic units (au); they correspond to the surface encompassing about 98% of the electron charge density in H_2SO_4 and $SO_4{}^{2-}$. If we choose a surface with a higher charge density value, then we include less of the electron charge distribution. Below the 98% surfaces are two electron charge density plots at increasing densities for the surfaces being calculated, also shown in Figure 11-43. What do these tell us? When we reach a density for the calculated surface just greater than the density at the bond critical point, the electron density in that bond disappears and we have established the amount of electron charge density in that bond. If there are bonds in the molecule that have more electron density at their bond critical points, then electron density will still appear in the three-dimensional representation. To illustrate this point, observe that at 0.22 au of electron charge density, the electron density between the sulfur atom and the two oxygen atoms attached to hydrogen atoms has disappeared (the stick from the ball-and-stick model is



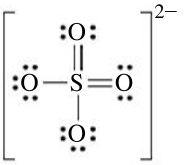
◀ FIGURE 11-43
Three-dimensional plots of the electron density in H_2SO_4 and $SO_4{}^{2-}$
The values for the outer isodensity envelope are set at 0.002 au, 0.22 au, and 0.28 au in the three figures for both species.

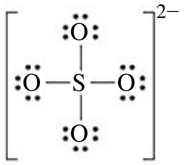
apparent), but between the sulfur and the two oxygen atoms that do not have a hydrogen atom, it is still visible. The electron density between the sulfur atom and the nonprotonated oxygen (the oxygen atom that does not have a hydrogen attached) atoms does not disappear until the density of the calculated surface is increased to 0.33 au. We conclude that there is more electron density in the bonds between the sulfur atom and the nonprotonated oxygen atoms than in the bonds between sulfur and oxygen attached to a proton. This extra electron density can be represented in a Lewis structure that places a double bond between the central S atom and the two terminal O atoms, thereby reducing the formal charges seen in the octet Lewis structure of H_2SO_4.





In considering the electron density surface for the sulfate anion, we see that the bond critical density is 0.28 au for the four bonds between the sulfur atom and the oxygen atoms. This is similar to that for the bond between sulfur and the nonprotonated oxygen atoms and greater than that for the sulfur–oxygen bonds attached to protonated oxygen atoms. The presence of this higher bond critical point in the sulfate anion suggests that maybe the Lewis structure that minimizes formal charges is the best. All four sulfur–oxygen bonds have the same bond critical point, which corresponds to the possible resonance structures that can be written.





We have reached a point at which minimizing the formal charges by using expanded valence shells seems best. However, one detailed analysis of the wavefunction of the sulfate anion suggests that the dominant form is the simple octet structure that does not minimize the formal charge.*

How Should We Proceed? What Is the Correct Formulation?

Perhaps the answer to the several questions posed in this section lies in the work of R. J. Gillespie, a coauthor of the VSEPR method. He proposes that Lewis structures be written as Lewis would have written them—that is, with no expanded valence shells. In cases of highly polar bonds, there can be, simultaneously, considerable electron density between the atoms (a significantly covalent bond) *and* a large charge separation between the atoms (a significantly ionic bond). These two factors provide a better understanding of the strength of polar covalent bonds in molecules such as BF_3 (with a B—F bond dissociation enthalpy of 613 kJ/mol) or SiF_4 (with a Si—F bond dissociation enthalpy of 567 kJ/mol). By contrast, the nonpolar covalent C—C bond dissociation enthalpy is only 345 kJ/mol. An analysis of the electron densities in BF_3 and SiF_4 shows that they do have a combination of highly covalent and ionic bond characteristics, leading to very strong bonds.

The controversy as to how best to write Lewis structures will no doubt continue in the chemical literature, but you should not be too dismayed by this situation. Our approach to depicting the electronic structure of a molecule is based on the simplest Lewis structure and its concomitant use in determining

---

*L. Suidan, J. K. Badenhoop, E. D. Glendenning, and F. Weinhold, *J. Chem. Educ.*, **72,** 583 (1995).

the shape of a molecule through VSEPR theory. In order to probe more deeply into the nature of a chemical bond—for example, to understand experimental results, such as bond enthalpy values—we must analyze a computed electron density map for that molecule rather than rely just on the Lewis structure.

MasteringCHEMISTRY www.masteringchemistry.com

The orbital structures of molecules are studied using photoelectron spectroscopy. The method involves passing high-energy photons through a gaseous sample of molecules, and measuring the kinetic energies of the ejected electrons. For a discussion of Photoelectron Spectroscopy, go to the Focus On feature for Chapter 11 on the MasteringChemistry site.

Summary

11-1 What a Bonding Theory Should Do—A basic requirement of a bonding theory is that it provide a better description of the electronic structure of molecules than the simple ideas of the Lewis model.

11-2 Introduction to the Valence-Bond Method—**Valence-bond method** considers a covalent bond in terms of the overlap of atomic orbitals of the bonded atoms.

11-3 Hybridization of Atomic Orbitals—Some molecules can be described in terms of the overlap of simple orbitals, but often orbitals that are a composite of simple orbitals—**hybrid orbitals**—are needed. The **hybridization** scheme chosen is the one that produces an orientation of hybrid orbitals to match the electron-group geometry predicted by the VSEPR theory (Fig. 11-13). ***sp* hybrid orbitals** (Fig. 11-10) are associated with linear electron-group geometries; **sp^2 hybrid orbitals** (Fig. 11-9) with trigonal planar geometries; **sp^3 hybrid orbitals** (Fig. 11-6) with tetrahedral geometries; **sp^3d hybrid orbitals** with trigonal bipyramidal geometries; and **sp^3d^2 hybrid orbitals** (Fig. 11-12) with octahedral geometries.

11-4 Multiple Covalent Bonds—End-to-end overlap of orbitals produces **σ (sigma) bonds**. Side-to-side overlap of two *p* orbitals produces a **π (pi) bond**. Single covalent bonds are σ bonds. A double bond consists of one σ bond and one π bond (Fig. 11-14). A triple bond consists of one σ bond and two π bonds (Fig. 11-16). The geometric shape of a species determines the σ-bond framework, and π bonds are added as required to complete the bonding description.

11-5 Molecular Orbital Theory—In **molecular orbital theory**, electrons are assigned to molecular orbitals. The numbers and kinds of molecular orbitals are related to the atomic orbitals used to generate them. Electron charge density between atoms is high in **bonding molecular orbitals** and very low in **antibonding orbitals** (Fig. 11-21). **Bond order** is one-half the difference between the numbers of electrons in bonding molecular orbitals and in antibonding molecular orbitals (equation 11.1). Molecular orbital energy-level diagrams and an aufbau process can be used to describe the electronic structure of a molecule; this is similar to what was done for atomic electron configurations in Chapter 8.

11-6 Delocalized Electrons: Bonding in the Benzene Molecule—Bonding in the benzene molecule, C_6H_6, is partly based on the concept of **delocalized molecular orbitals**. These are regions of high electron charge density that extend over several atoms in a molecule (Fig. 11-31). Delocalized molecular orbitals also provide an alternative to the concept of resonance in other molecules and ions.

11-7 Bonding in Metals—Molecular orbital theory, in the form called **band theory**, can be applied to metals, semiconductors, and insulators (Fig. 11-38). Band theory explains thermal and electric conductivity, the ease of deformation, and the characteristic luster of metals. It also explains the colors of semiconductors and the fact that their electric conductivities increase with temperature.

11-8 Some Unresolved Issues—Can Electron Charge-Density Plots Help?—Charge-density plots can be used as a guide in understanding the bonding in molecules that don't necessarily have simple Lewis structures. In molecules such as SF6, we employed the concept of hyperconjugation. For SCl_2 the electron density was analyzed in terms of bond paths and bond critical points. For H_2SO_4 and SO_4^{2-}, bond critical points derived from charge density point out that drawing Lewis structures with the lowest formal charge is one of the best ways to represent the bonding in these compounds. In general one should write Lewis structures without expanded valence shells.

Integrative Example

Hydrogen azide, HN_3, and its salts (metal azides) are unstable substances used in detonators for high explosives. Sodium azide, NaN_3, is used in air-bag safety systems in automobiles (see page 210). A reference source lists the following data for HN_3. (The subscripts a, b, and c distinguish the three N atoms from one another.) Bond lengths: $N_a—N_b = 124$ pm; $N_b—N_c = 113$ pm. Bond angles: $H—N_a—N_b = 112.7°$; $N_a—N_b—N_c = 180°$.

Write two contributing structures to the resonance hybrid for HN_3, and describe a plausible hybridization and bonding scheme for each structure.

Analyze

We can use data from Table 10.2 to estimate the bond order for the two nitrogen-to-nitrogen bonds. From this information we can write plausible Lewis structures, and by applying VSEPR theory to the Lewis structures, we can predict a likely geometric shape of the molecule. Finally, with this information we can propose hybridization schemes for the central atoms and an overall bonding scheme for the molecule.

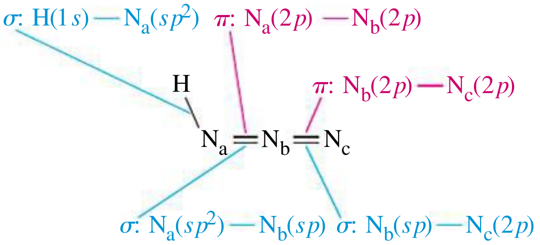
Solve

From Table 10.2, the average bond lengths for N-to-N bonds are 145 pm for a single bond, 123 pm for a double bond, and 110 pm for a triple bond. Thus it is likely that the $N_a—N_b$ bond (124 pm) has a considerable double-bond character, and the $N_b—N_c$ bond (113 pm) has a considerable triple-bond character.

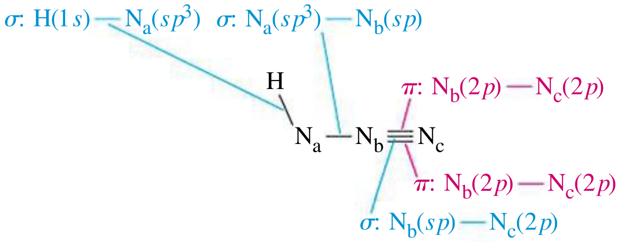
The HN_3 molecule has a total of 16 valence electrons in 8 electron pairs. The plausible Lewis structures have N_a and N_b atoms as central atoms, the N_c and H atoms as terminal atoms, and bonds reflecting the observed bond lengths.

(I) $H—\ddot{N}_a{=}N_b{=}\underset{\cdot\cdot}{\ddot{N}}_c$ (II) $H—\underset{\cdot\cdot}{\ddot{N}}_a—N_b{\equiv}\ddot{N}_c$

According to VSEPR theory, in both structures (I) and (II) the electron-group geometry around N_b is linear. This corresponds to *sp* hybridization. In structure (I), the electron-group geometry around N_a is trigonal-planar, corresponding to sp^2 hybridization; in structure (II), the electron-group geometry around N_a is tetrahedral, corresponding to sp^3 hybridization. These hybridization schemes, the orbital overlaps, and the geometric structures of the two resonance structures are indicated on the right.



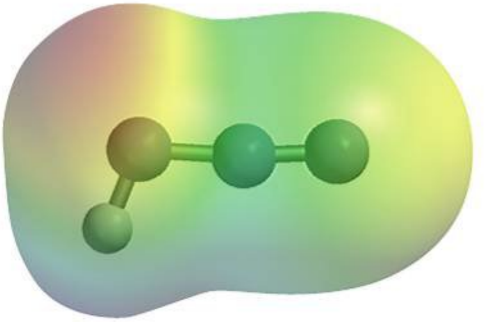
Structure (I)



Structure (II)

Assess

Of these two resonance structures, which is the most favorable? We could try to use formal charges, but we find that in structure (I), the formal charges on N_a, N_b, and N_c, are 0, +1, and −1, respectively; correspondingly in structure (II), the formal charges are −1, +1, and 0, respectively. Because the formal charges are so similar, we cannot make any definitive conclusion as to which structure is favored. The surest way to decide is to compare the observed molecular structure with that suggested by the two hybridization-schemes given above. In structure (I), N_a is sp^2 hybridized so that a $H—N_a—N_b$ angle is expected to be close to 120°; whereas in structure (II), the hybridization on N_a is sp^3 so that the $H—N_a—N_b$ angle is expected to be close to 109°. Experimentally it is found that the $H—N_a—N_b$ angle is 109°, so that the hybridization scheme in structure (II) is to be preferred. The electrostatic potential map for HN_3 is shown on the right, and we observe that N_a is relatively negatively charged as compared to N_b and N_c—in accord with our preferred structure (II).



PRACTICE EXAMPLE A: Melamine is a carbon–hydrogen–nitrogen compound used in the manufacture of adhesives, protective coatings, and textile finishing (such as in wrinkle-free, wash-and-wear fabrics). Its mass percent composition is 28.57% C, 4.80% H, and 66.64% N. The melamine molecule features a six-member ring with alternating carbon and nitrogen atoms. Half the nitrogen atoms and all the H atoms are outside the ring. For melamine, **(a)** write a plausible Lewis structure, **(b)** describe bonding in the molecule by the valence-bond method, and **(c)** describe bonding in the ring system through molecular orbital theory.

PRACTICE EXAMPLE B: Dimethylglyoxime (DMG) is a carbon–hydrogen–nitrogen–oxygen compound with a molecular mass of 116.12 u. In a combustion analysis, a 2.464 g sample of DMG yields 3.735 g CO_2 and 1.530 g H_2O. In a separate experiment, the nitrogen in a 1.868 g sample of DMG is converted to $NH_3(g)$ and the NH_3 is neutralized by passing it into 50.00 mL of 0.3600 M $H_2SO_4(aq)$. After neutralization of the NH_3 the excess $H_2SO_4(aq)$ requires 18.63 mL of 0.2050 M NaOH(aq) for its neutralization. Using these data, determine for dimethylglyoxime **(a)** the most plausible Lewis structure, and **(b)** in the manner of Figure 11-18, a plausible bonding scheme.

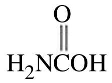
Exercises

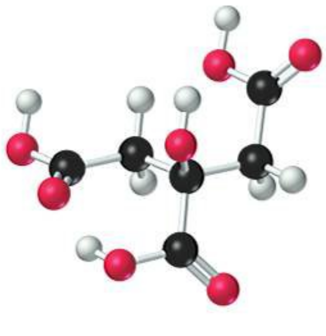
Valence-Bond Method

1. Indicate several ways in which the valence-bond method is superior to Lewis structures in describing covalent bonds.
2. Explain why it is necessary to hybridize atomic orbitals when applying the valence-bond method—that is, why are there so few molecules that can be described by the overlap of pure atomic orbitals only?
3. Describe the molecular geometry of H_2O suggested by each of the following methods: **(a)** Lewis theory; **(b)** valence-bond method using simple atomic orbitals; **(c)** VSEPR theory; **(d)** valence-bond method using hybridized atomic orbitals.
4. Describe the molecular geometry of CCl_4 suggested by each of the following methods: **(a)** Lewis theory; **(b)** valence-bond method using simple atomic orbitals; **(c)** VSEPR theory; **(d)** valence-bond method using hybridized atomic orbitals.
5. In which of the following, CO_3^{2-}, SO_2, CCl_4, CO, NO_2^-, would you expect to find sp^2 hybridization of the central atom? Explain.
6. In the manner of Example 11-1, describe the probable structure and bonding in **(a)** HI; **(b)** BrCl; **(c)** H_2Se; **(d)** OCl_2.
7. For each of the following species, identify the central atom(s) and propose a hybridization scheme for those atom(s): **(a)** CO_2; **(b)** $HONO_2$; **(c)** ClO_3^-; **(d)** BF_4^-.
8. Propose a plausible Lewis structure, geometric structure, and hybridization scheme for the NSF molecule.
9. Describe a hybridization scheme for the central Cl atom in the molecule ClF_3 that is consistent with the geometric shape pictured in Table 10.1. Which orbitals of the Cl atom are involved in overlaps, and which are occupied by lone-pair electrons?
10. Describe a hybridization scheme for the central S atom in the molecule SF_4 that is consistent with the geometric shape pictured in Table 10.1. Which orbitals of the S atom are involved in overlaps, and which are occupied by lone-pair electrons?
11. Match each of the following species with one of these hybridization schemes: sp, sp^2, sp^3, sp^3d, sp^3d^2. **(a)** PF_6^-; **(b)** COS; **(c)** $SiCl_4$; **(d)** NO_3^-; **(e)** AsF_5.
12. Propose a hybridization scheme to account for bonds formed by the central carbon atom in each of the following molecules: **(a)** hydrogen cyanide, HCN; **(b)** methyl alcohol, CH_3OH; **(c)** acetone, $(CH_3)_2CO$; **(d)** carbamic acid,

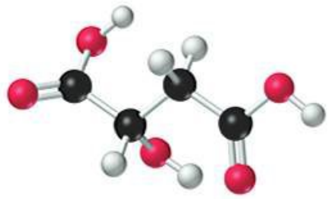


$$H_2N\overset{\overset{\displaystyle O}{\|}}{C}OH$$

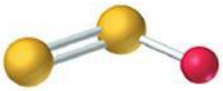
13. Indicate which of the following molecules and ions are linear, which are planar, and which are neither. Then propose hybridization schemes for the central atoms. **(a)** $Cl_2C{=}CCl_2$; **(b)** $N{\equiv}C{-}C{\equiv}N$; **(c)** $F_3C{-}C{\equiv}N$; **(d)** $[S{-}C{\equiv}N]^-$.
14. In the manner of Figure 11-17, indicate the structures of the following molecules in terms of the overlap of simple atomic orbitals and hybrid orbitals: **(a)** CH_2Cl_2; **(b)** OCN^-; **(c)** BF_3.
15. Write Lewis structures for the following molecules, and then label each σ and π bond. **(a)** HCN; **(b)** C_2N_2; **(c)** $CH_3CHCHCCl_3$; **(d)** HONO.
16. Represent bonding in the carbon dioxide molecule, CO_2, by **(a)** a Lewis structure and **(b)** the valence-bond method. Identify σ and π bonds, the necessary hybridization scheme, and orbital overlap.
17. Use the method of Figure 11-18 to represent bonding in each of the following molecules: **(a)** CCl_4; **(b)** ONCl; **(c)** HONO; **(d)** $COCl_2$.
18. Use the method of Figure 11-18 to represent bonding in each of the following ions: **(a)** NO_2^-; **(b)** I_3^-; **(c)** $C_2O_4^{2-}$; **(d)** HCO_3^-.
19. The molecular model below represents citric acid, an acidic component of citrus juices. Represent bonding in the citric acid molecule using the method of Figure 11-18 to indicate hybridization schemes and orbital overlaps.



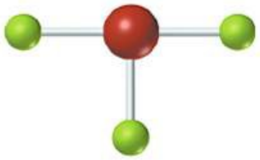
20. Malic acid is a common organic acid found in unripe apples and other fruit. With the help of the molecular model shown below, represent bonding in the malic acid molecule, using the method of Figure 11-18 to indicate hybridization schemes and orbital overlaps.



21. Shown below are ball-and-stick models. Describe hybridization and orbital-overlap schemes consistent with these structures.

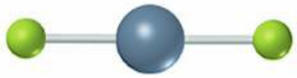


(a) S_2O

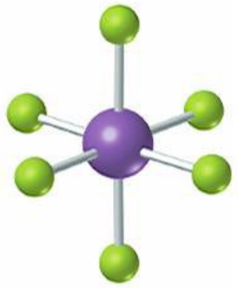


(b) BrF_3

22. Shown below are ball-and-stick models. Describe hybridization and orbital-overlap schemes consistent with these structures.

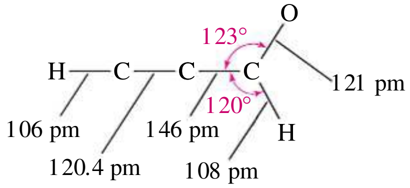


(a) XeF_2

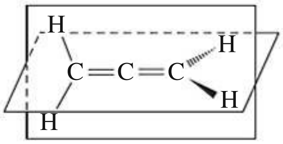


(b) $IF_6{}^+$

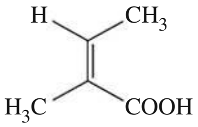
23. Propose a bonding scheme that is consistent with the structure for propynal. [*Hint:* Consult Table 10.2 to assess the multiple-bond character in some of the bonds.]



24. The structure of the molecule allene, CH_2CCH_2, is shown here. Propose hybridization schemes for the C atoms in this molecule.

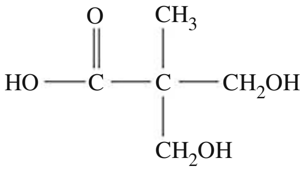


25. Angelic acid, shown below, occurs in sumbol root, a herb used as a stimulant.



Represent the bonding in the angelic acid molecule by using the method in Figure 11-18 to indicate hybridization schemes and orbital overlaps. What is the maximum number of atoms that can lie in the same plane?

26. Dimethylolpropionic acid, shown below, is used in the preparation of resins.



$$\mathrm{HO{-}\overset{\overset{\displaystyle O}{\|}}{C}{-}\underset{\underset{\displaystyle CH_2OH}{|}}{\overset{\overset{\displaystyle CH_3}{|}}{C}}{-}CH_2OH}$$

Represent the bonding in the dimethylolpropionic acid molecule by using the method in Figure 11-18 to indicate hybridization schemes and orbital overlaps. What is the maximum number of atoms that can lie in the same plane?

Molecular Orbital Theory

27. Explain the essential difference in how the valence-bond method and molecular orbital theory describe a covalent bond.

28. Describe the bond order of diatomic carbon, C_2, with Lewis theory and molecular orbital theory, and explain why the results are different.

29. $N_2(g)$ has an exceptionally high bond energy. Would you expect either $N_2{}^-$ or $N_2{}^{2-}$ to be a stable diatomic species in the gaseous state? Explain.

30. The paramagnetism of gaseous B_2 has been established. Explain how this observation confirms that the π_{2p} orbitals are at a lower energy than the σ_{2p} orbital for B_2.

31. In our discussion of bonding, we have not encountered a bond order higher than triple. Use the energy-level diagrams of Figure 11-26 to show why this is to be expected.

32. Is it correct to say that when a diatomic molecule loses an electron, the bond energy always decreases (that is, that the bond is always weakened)? Explain.

33. For the following pairs of molecular orbitals, indicate the one you expect to have the lower energy, and state the reason for your choice. **(a)** σ_{1s} or σ^*_{1s}; **(b)** σ_{2s} or σ_{2p}; **(c)** σ^*_{1s} or σ_{2s}; **(d)** σ_{2p} or σ^*_{2p}.

34. For each of the species C_2^+, O_2^-, F_2^+, and NO^+,
(a) Write the molecular orbital diagram (as in Example 11-6).
(b) Determine the bond order, and state whether you expect the species to be stable or unstable.
(c) Determine if the species is diamagnetic or paramagnetic; and if paramagnetic, indicate the number of unpaired electrons.

35. Write plausible molecular orbital diagrams for the following *heteronuclear* diatomic species: **(a)** NO; **(b)** NO^+; **(c)** CO; **(d)** CN; **(e)** CN^-; **(f)** CN^+; **(g)** BN.

36. We have used the term "isoelectronic" to refer to atoms with identical electron configurations. In molecular orbital theory, this term can be applied to molecular species as well. Which of the species in Exercise 35 are isoelectronic?

37. Consider the molecules NO^+ and N_2^+ and use molecular orbital theory to answer the following:
(a) Write the molecular orbital configuration of each ion (ignore the 1*s* electrons).
(b) Predict the bond order of each ion.
(c) Which of these ions is paramagnetic? Which is diamagnetic?
(d) Which of these ions do you think has the greater bond length? Explain.

38. Consider the molecules CO^+ and CN^- and use molecular orbital theory to answer the following:
(a) Write the molecular orbital configuration of each ion (ignore the 1*s* electrons).
(b) Predict the bond order of each ion.
(c) Which of these ions is paramagnetic? Which is diamagnetic?
(d) Which of these ions do you think has the greater bond length? Explain.

39. Construct the molecular orbital diagram for CF. Would you expect the bond length of CF^+ to be longer or shorter than that of CF?

40. Construct the molecular orbital diagram for CaF. Would you expect the bond length of CaF^+ to be longer or shorter than that of CaF?

Delocalized Molecular Orbitals

41. Explain why the concept of delocalized molecular orbitals is essential to an understanding of bonding in the benzene molecule, C_6H_6.

42. Explain how it is possible to avoid the concept of resonance by using molecular orbital theory.

43. In which of the following molecules would you expect to find delocalized molecular orbitals: **(a)** C_2H_4; **(b)** SO_2; **(c)** H_2CO? Explain.

44. In which of the following ions would you expect to find delocalized molecular orbitals: **(a)** HCO_2^-; **(b)** CO_3^{2-}; **(c)** CH_3^+? Explain.

Metallic Bonding

45. Which of the following factors are especially important in determining whether a substance has metallic properties: **(a)** atomic number; **(b)** atomic mass; **(c)** number of valence electrons; **(d)** number of vacant atomic orbitals; **(e)** total number of electronic shells in the atom? Explain.

46. Based on the ground-state electron configurations of the atoms, how would you expect the melting points and hardnesses of sodium, iron, and zinc to compare? Explain.

47. How many energy levels are present in the 3*s* conduction band of a single crystal of sodium weighing 26.8 mg? How many electrons are present in this band?

48. Magnesium is an excellent electrical conductor even though it has a full 3*s* subshell with the electron configuration: $[\mathrm{Ne}]3s^2$. Use band theory to explain why magnesium conducts electricity.

Semiconductors

49. From this list of terms—electrical conductor, insulator, semiconductor—choose the one that best characterizes each of the following materials: **(a)** stainless steel; **(b)** solid sodium chloride; **(c)** sulfur; **(d)** germanium; **(e)** seawater; **(f)** solid iodine.

50. In what type of material is the energy gap between the valence band and the conduction band greatest: metal, semiconductor, or insulator? Explain.

51. Which of the following substances, when added in trace amounts to silicon, would produce a *p*-type semiconductor: **(a)** sulfur, **(b)** arsenic, **(c)** lead, **(d)** boron, **(e)** gallium arsenide, **(f)** gallium? Explain.

52. Which of the following substances, when added in trace amounts to germanium, would produce an *n*-type semiconductor: **(a)** sulfur, **(b)** aluminum, **(c)** tin, **(d)** cadmium sulfide, **(e)** arsenic, **(f)** gallium arsenide? Explain.

53. The effect of temperature change on the electrical conductivity of ultrapure silicon is quite different from that on silicon containing a minute trace of arsenic. Why is this so?

54. Explain why the electrical conductivity of a semiconductor is significantly increased if trace amounts of either donor or acceptor atoms are present, but is unchanged if both are present in equal number.

55. The energy gap, ΔE, for silicon is 110 kJ/mol. What is the minimum wavelength of light that can promote an electron from the valence band to the conduction band in silicon? In what region of the electromagnetic spectrum is this light?

56. Explain why the solar cell in Figure 11-40 operates over a broad range of wavelengths rather than at a single wavelength (often the case when quantum effects are involved)?

Integrative and Advanced Exercises

57. The Lewis structure of N_2 indicates that the nitrogen-to-nitrogen bond is a triple covalent bond. Other evidence suggests that the σ bond in this molecule involves the overlap of *sp* hybrid orbitals.
(a) Draw orbital diagrams for the N atoms to describe bonding in N_2.
(b) Can this bonding be described by either sp^2 or sp^3 hybridization of the N atoms? Can bonding in N_2 be described in terms of unhybridized orbitals? Explain.

58. Show that both the valence-bond method and molecular orbital theory provide an explanation for the existence of the covalent molecule Na_2 in the gaseous state. Would you predict Na_2 by the Lewis theory?

59. A group of spectroscopists believe that they have detected one of the following species: NeF, NeF^+, or NeF^-. Assume that the energy-level diagrams of Figure 11-26 apply, and describe bonding in these species. Which of these species would you expect the spectroscopists to have observed?

60. Lewis theory is satisfactory to explain bonding in the ionic compound K_2O, but it does not readily explain formation of the ionic compounds potassium superoxide, KO_2, and potassium peroxide, K_2O_2.
(a) Show that molecular orbital theory can provide this explanation.
(b) Write Lewis structures consistent with the molecular orbital explanation.

61. The compound potassium sesquoxide has the empirical formula K_2O_3. Show that this compound can be described by an appropriate combination of potassium, peroxide, and superoxide ions. Write a Lewis structure for a formula unit of the compound.

62. Draw a Lewis structure for the urea molecule, $CO(NH_2)_2$, and predict its geometric shape with the VSEPR theory. Then revise your assessment of this molecule, given the fact that all the atoms lie in the same plane, and all the bond angles are 120°. Propose a hybridization and bonding scheme consistent with these experimental observations.

63. Methyl nitrate, CH_3NO_3, is used as a rocket propellant. The skeletal structure of the molecule is CH_3ONO_2. The N and three O atoms all lie in the same plane, but the CH_3 group is not in the same plane as the NO_3 group. The bond angle $C—O—N$ is 105°, and the bond angle $O—N—O$ is 125°. One nitrogen-to-oxygen bond length is 136 pm, and the other two are 126 pm.
(a) Draw a sketch of the molecule showing its geometric shape.
(b) Label all the bonds in the molecule as σ or π, and indicate the probable orbital overlaps involved.
(c) Explain why all three nitrogen-to-oxygen bond lengths are not the same.

64. Fluorine nitrate, $FONO_2$, is an oxidizing agent used as a rocket propellant. A reference source lists the following data for FO_aNO_2. (The subscript "a" shows that this O atom is different from the other two.)

Bond lengths: $N—O = 129$ pm;
$N—O_a = 139$ pm; $O_a—F = 142$ pm
Bond angles: $O—N—O = 125°$;
$F—O_a—N = 105°$
NO_aF plane is perpendicular to the O_2NO_a plane

Use these data to construct a Lewis structure(s), a three-dimensional sketch of the molecule, and a plausible bonding scheme showing hybridization and orbital overlaps.

65. Draw a Lewis structure(s) for the nitrite ion, NO_2^-. Then propose a bonding scheme to describe the σ and π bonding in this ion. What conclusion can you reach about the number and types of π molecular orbitals in this ion? Explain.

66. Think of the reaction shown here as involving the transfer of a fluoride ion from ClF_3 to AsF_5 to form the ions ClF_2^+ and AsF_6^-. As a result, the hybridization scheme of each central atom must change. For each reactant molecule and product ion, indicate **(a)** its geometric structure and **(b)** the hybridization scheme for its central atom.

$$ClF_3 + AsF_5 \longrightarrow (ClF_2^+)(AsF_6^-)$$

67. In the gaseous state, HNO_3 molecules have two nitrogen-to-oxygen bond distances of 121 pm and one of 140 pm. Draw a plausible Lewis structure(s) to represent this fact, and propose a bonding scheme in the manner of Figure 11-18.

68. He_2 does not exist as a stable molecule, but there is evidence that such a molecule can be formed between electronically excited He atoms. Write a molecular orbital diagram to account for this.

69. The molecule formamide, $HCONH_2$, has the approximate bond angles $H—C—O$, 123°; $H—C—N$, 113°; $N—C—O$, 124°; $C—N—H$, 119°; $H—N—H$, 119°. The $C—N$ bond length is 138 pm. Two Lewis structures can be written for this molecule, with the true structure being a resonance hybrid of the two. Propose a hybridization and bonding scheme for each structure.

70. Pyridine, C_5H_5N, is used in the synthesis of vitamins and drugs. The molecule can be thought of in terms of replacing one CH unit in benzene with a N atom. Draw orbital diagrams to show the orbitals of the C and N atoms involved in the σ and π bonding in pyridine. How many bonding and antibonding π-type molecular orbitals are present? How many delocalized electrons are present?

71. One of the characteristics of antibonding molecular orbitals is the presence of a nodal plane. Which of the bonding molecular orbitals considered in this chapter have nodal planes? Explain how a molecular orbital can have a nodal plane and still be a bonding molecular orbital.

72. The ion F_2Cl^- is linear, but the ion F_2Cl^+ is bent. Describe hybridization schemes for the central Cl atom consistent with this difference in structure.

73. Ethyl cyanoacetate, a chemical used in the synthesis of dyes and pharmaceuticals, has the mass percent composition: 53.09% C, 6.24% H, 12.39% N, and 28.29% O. In the manner of Figure 11-18, show a bonding scheme for this substance. The scheme should designate orbital overlaps, σ and π bonds, and expected bond angles.

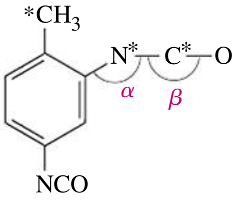
74. A certain monomer used in the production of polymers has one nitrogen atom and the mass composition 67.90% C, 5.70% H, and 26.40% N. Sketch the probable geometric structure of this molecule, labeling all the expected bond lengths and bond angles.

75. A solar cell that is 15% efficient in converting solar to electric energy produces an energy flow of 1.00 kW/m^2 when exposed to full sunlight.

(a) If the cell has an area of 40.0 cm^2, what is the power output of the cell, in watts?

(b) If the power calculated in part (a) is produced at 0.45 V, how much current does the cell deliver?

76. Toluene-2,4-diisocyanate is used in the manufacture of polyurethane foam. Its structural formula is shown here. Describe the hybridization scheme for the atoms marked with an asterisk, and indicate the values of the bond angles marked α and β.



77. The anion I_4^{2-} is linear, and the anion I_5^- is V-shaped, with a 95° angle between the two arms of the V. For the central atoms in these ions, propose hybridization schemes that are consistent with these observations.

78. Pentadiene, C_5H_8, has three isomers, depending on the position of the two double bonds. Determine the shape of these isomers by using VSEPR theory. Describe the bonding in these molecules by using the valence-bond method. Do the shapes agree in the two theories? Use molecular orbital theory to decide which of these molecules has a delocalized π system. Sketch the molecular orbital and an energy-level diagram.

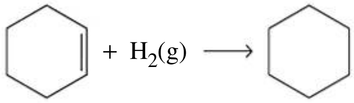
79. A conjugated hydrocarbon has an alternation of double and single bonds. Draw the molecular orbitals of the π system of 1,3,5-hexatriene. If the energy required to excite an electron from the HOMO to the LUMO corresponds to a wavelength of 256 nm, do you expect the wavelength for the corresponding excitation in 1,3,5,7-octatetraene to be a longer or shorter wavelength?

Feature Problems

80. Resonance energy is the difference in energy between a real molecule—a resonance hybrid—and its most important contributing structure. To determine the resonance energy for benzene, we can determine an energy change for benzene and the corresponding change for one of the Kekulé structures. The resonance energy is the difference between these two quantities.

(a) Use data from Appendix D to determine the enthalpy of hydrogenation of liquid benzene to liquid cyclohexane.

(b) Use data from Appendix D to determine the enthalpy of hydrogenation of liquid cyclohexene to liquid cyclohexane.



For the enthalpy of formation of liquid cyclohexene, use $\Delta H_f^\circ = -38.5$ kJ/mol.

(c) Assume that the enthalpy of hydrogenation of 1,3,5-cyclohexatriene is three times as great as that of cyclohexene, and calculate the resonance energy of benzene.

(d) Another way to assess resonance energy is through bond energies. Use bond energies from Table 10.3 (page 435) to determine the total enthalpy change required to break all the bonds in a Kekulé structure of benzene. Next, determine the enthalpy change for the dissociation of $C_6H_6(g)$ into its gaseous atoms by using data from Table 10.3 and Appendix D. Then calculate the resonance energy of benzene.

81. The 60-cycle alternating electric current (AC) commonly used in households changes direction 120 times per second. That is, in a one-second time period a terminal at an electric outlet is positive 60 times and negative 60 times. In direct electric current (DC), the flow between terminals is in one direction only. A *rectifier* is a device that converts alternating to direct current. One type of rectifier is the *p–n* junction rectifier. It is commonly incorporated in adapters required to operate electronic devices from ordinary house current. In the operation of this rectifier, a *p*-type semiconductor and an *n*-type semiconductor are in contact along a boundary, or junction. Each semiconductor is connected to one of the terminals in an AC electrical outlet. Describe how this rectifier works. That is, show that when the semiconductors are connected to the terminals in an AC outlet, half the time a large flow of charge occurs and half the time essentially no charge flows across the *p–n* junction.

82. Furan, C_4H_4O, is a substance derivable from oat hulls, corn cobs, and other cellulosic waste. It is a starting material for the synthesis of other chemicals used as pharmaceuticals and herbicides. The furan molecule is planar and the C and O atoms are bonded into a five-membered pentagonal ring. The H atoms are attached to the C atoms. The chemical behavior of the molecule suggests that it is a resonance hybrid of several contributing structures. These structures show that the double bond character is associated with the entire ring in the form of a π electron cloud.

(a) Draw Lewis structures for the several contributing structures to the resonance hybrid mentioned above.

(b) Draw orbital diagrams to show the orbitals that are involved in the σ and π bonding in furan. [*Hint:* You need use only one of the contributing structures, such as the one with no formal charges.]

(c) How many π electrons are there in the furan molecule? Show that this number of π electrons is the same, regardless of the contributing structure you use for this assessment.

83. As discussed in the Are You Wondering feature on page 457, the *sp* hybrid orbitals are algebraic combinations of the *s* and *p* orbitals. The required combinations of 2*s* and 2*p* orbitals are

$$\psi_1(sp) = \frac{1}{\sqrt{2}}[\psi(2s) + \psi(2p_z)]$$

$$\psi_2(sp) = \frac{1}{\sqrt{2}}[\psi(2s) - \psi(2p_z)]$$

(a) By combining the appropriate functions given in Table 8.1, construct a polar plot in the manner of Figure 8-26 for each of the above functions in the *xz* plane. In a polar plot, the value of r/a_0 is set at a fixed value (for example, 1). Describe the shapes and phases of the different portions of the hybrid orbitals, and compare them with those shown in Figure 11-11.

(b) Convince yourself that the combinations employing the $2p_x$ or $2p_y$ orbital also give similar hybrid orbitals but pointing in different directions.

(c) The combinations for the sp^2 hybrids in the *xy* plane are

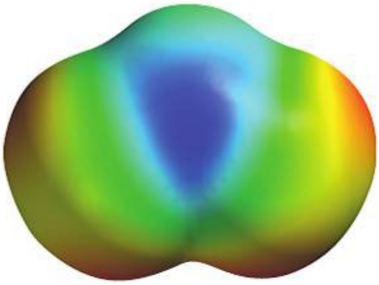
$$\psi_1(sp^2) = \frac{1}{\sqrt{3}}\psi(2s) + \frac{\sqrt{2}}{\sqrt{3}}\psi(2p_x)$$

$$\psi_2(sp^2) = \frac{1}{\sqrt{3}}\psi(2s) - \frac{1}{\sqrt{6}}\psi(2p_x) + \frac{1}{\sqrt{2}}\psi(2p_y)$$

$$\psi_3(sp^2) = \frac{1}{\sqrt{3}}\psi(2s) - \frac{1}{\sqrt{6}}\psi(2p_x) - \frac{1}{\sqrt{2}}\psi(2p_y)$$

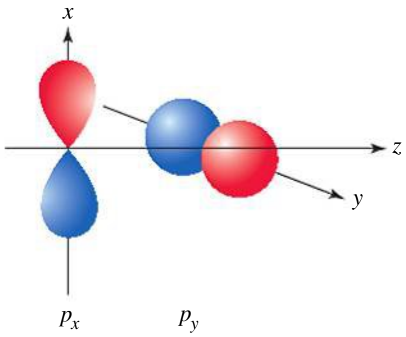
By constructing polar plots (in the *xy* plane), show that these functions correspond to the sp^2 hybrids depicted in Figure 11-9.

84. In Chapter 10, we saw that electronegativity differences determine whether bond dipoles exist in a molecule and that molecular shape determines whether bond dipoles cancel (nonpolar molecules) or combine to produce a resultant dipole moment (polar molecules). Thus, the ozone molecule, O_3, has no bond dipoles because all the atoms are alike. Yet, O_3 *does* have a resultant dipole moment: $\mu = 0.534$ D. The electrostatic potential map for ozone is shown below. Use the electrostatic potential map to decide the direction of the dipole. Using the ideas of delocalized bonding in molecules, can you rationalize this electrostatic potential map?

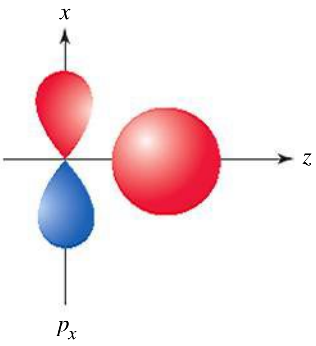


85. Borazine, $B_3N_3H_6$ is often referred to as inorganic benzene because of its similar structure. Like benzene, borazine has a delocalized π system. Describe the molecular orbitals of the π system. Identify the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO). How many nodes does the LUMO possess?

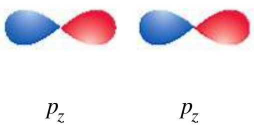
86. Which of the following combinations of orbitals give rise to bonding molecular orbitals? For those combinations that do, label the resulting bonding molecular orbital as *s* or *p*.



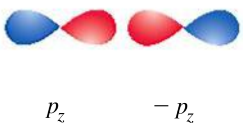
(a)



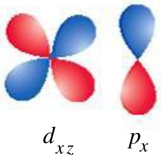
(b)



(c)



(d)



(e)

87. Construct a molecular orbital diagram for HF, and label the molecular orbitals as bonding, antibonding, or nonbonding.

Self-Assessment Exercises

88. In your own words, define the following terms or symbols: **(a)** sp^2; **(b)** σ^*_{2p}; **(c)** bond order; **(d)** π bond.

89. Briefly describe each of the following ideas: **(a)** hybridization of atomic orbitals; **(b)** σ-bond framework; **(c)** Kekulé structures of benzene, C_6H_6; **(d)** band theory of metallic bonding.

90. Explain the important distinctions between the terms in each of the following pairs: **(a)** σ and π bonds; **(b)** localized and delocalized electrons; **(c)** bonding and antibonding molecular orbitals; **(d)** metal and semiconductor.

91. A molecule in which sp^2 hybrid orbitals are used by the central atom in forming covalent bonds is **(a)** PCl_5; **(b)** N_2; **(c)** SO_2; **(d)** He_2.

92. The bond angle in H_2Se is best described as **(a)** between 109° and 120°; **(b)** less than in H_2S; **(c)** less than in H_2S, but not less than 90°; **(d)** less than 90°.

93. The hybridization scheme for the central atom includes a *d* orbital contribution in **(a)** I_3^-; **(b)** PCl_3; **(c)** NO_3^-; **(d)** H_2Se.

94. Of the following, the species with a bond order of 1 is **(a)** H_2^+; **(b)** Li_2; **(c)** He_2; **(d)** H_2^-.

95. The hybridization scheme for Xe in XeF_2 is **(a)** sp; **(b)** sp^3; **(c)** sp^3d; **(d)** sp^3d^2.

96. Delocalized molecular orbitals are found in **(a)** H_2; **(b)** HS^-; **(c)** CH_4; **(d)** CO_3^{2-}.

97. The best electrical conductor of the following materials is **(a)** Li(s); **(b)** Br_2(l); **(c)** Ge(s); **(d)** Si(s).

98. A substance in which the valence and conduction bands overlap is **(a)** a semiconductor; **(b)** a metalloid; **(c)** a metal; **(d)** an insulator.

99. Explain why the molecular structure of BF_3 cannot be adequately described through overlaps involving pure *s* and *p* orbitals.

100. Why does the hybridization sp^3d not account for bonding in the molecule BrF_5? What hybridization scheme does work? Explain.

101. What is the total number of **(a)** σ bonds and **(b)** π bonds in the molecule CH_3NCO?

102. Which of the following species are paramagnetic? **(a)** B_2; **(b)** B_2^-; **(c)** B_2^+. Which species has the strongest bond?

103. Use the valence molecular orbital configuration to determine which of the following species is expected to have the lowest ionization energy: **(a)** C_2^+; **(b)** C_2; **(c)** C_2^-.

104. Use the valence molecular orbital configuration to determine which of the following species is expected to have the greatest electron affinity: **(a)** C_2^+; **(b)** Be_2; **(c)** F_2; **(d)** B_2^+.

105. Which of these diatomic molecules do you think has the greater bond energy, Li_2 or C_2? Explain.

106. Construct a concept map that embodies the ideas of valence bond theory.

107. Construct a concept map that connects the ideas of molecular orbital theory.

108. Construct a concept map that describes the interconnection between valence-bond theory and molecular orbital theory in the description of resonance structures.

Intermolecular Forces: Liquids and Solids

CONTENTS

12-1 Intermolecular Forces
12-2 Some Properties of Liquids
12-3 Some Properties of Solids
12-4 Phase Diagrams
12-5 Network Covalent Solids and Ionic Solids
12-6 Crystal Structures
12-7 Energy Changes in the Formation of Ionic Crystals

In this scene from Antarctica, water exists in all three states of matter—solid in the ice, liquid in the sea, and gas in the atmosphere. Solids, liquids, and gases were compared at the macroscopic and microscopic levels in Chapter 1 (Fig. 1-7).

When we make ice cubes by placing water in a tray in a freezer, energy is removed from the water molecules, which gradually slow down. Attractive (intermolecular) forces between the molecules take over, and the water solidifies into ice. When an ice cube melts, energy from the surroundings is absorbed by the water molecules, which overcome the intermolecular forces within the ice cube and enter the liquid state. In our study of gases, we intentionally sought conditions in which the intermolecular forces were negligible. This approach allowed us to describe gases with the ideal gas equation and to explain their behavior with the kinetic-molecular theory of gases. To describe the other states of matter—liquids and solids—we must first be able to identify the various intermolecular forces and then find situations in which the intermolecular forces are significant. We then consider some interesting properties of liquids and solids related to the strengths of these forces.

▶ Two of the many natural phenomena described in this chapter include the more ordered structure of the solid compared with the liquid state and the variation of density with the state of matter.

12-1 Intermolecular Forces

In our study of gases, we noted that at high pressures and low temperatures intermolecular forces cause gas behavior to depart from ideality. When these forces are sufficiently strong, a gas condenses to a liquid. That is, the intermolecular forces keep the molecules in such close proximity that they are confined to a definite volume, as expected for the liquid state.

Intermolecular forces are important in establishing the form and behavior of matter. The origin of intermolecular forces, those interactions between molecules, arises from the permanent and momentary unequal distribution of electron density within molecules.

Van der Waals Forces

Because helium forms no stable chemical bonds, we might expect it to remain a gas right down to 0 K. Although helium remains gaseous to very low temperatures, it does condense to a liquid at 4 K and freeze to a solid (at 25 atm pressure) at 1 K. These data suggest that intermolecular forces, even though very weak, must exist among He atoms. If the temperature is sufficiently low, these forces overcome thermal agitation and cause helium to condense. In this section, we will examine the types of intermolecular forces known collectively as **van der Waals forces**. The intermolecular forces contributing to the term $a(n/V)^2$ in the van der Waals equation for nonideal gases (equation 6.26) are of this type.

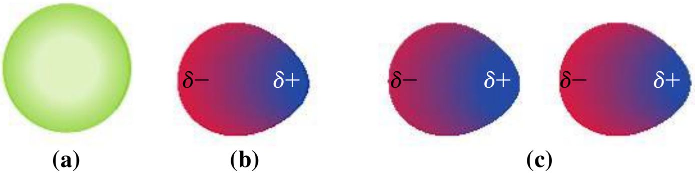
Instantaneous and Induced Dipoles

In describing electronic structures, we speak of electron charge density, or the probability that an electron is in a certain region at a given time. One probability is that at some particular instant—purely by chance—electrons are concentrated in one region of an atom or a molecule. This displacement of electrons causes a normally nonpolar species to become momentarily polar. An *instantaneous dipole* is formed. That is, the molecule has an instantaneous dipole moment. After this, electrons in a neighboring atom or molecule may be displaced to also produce a dipole. This is a process of induction (Fig. 12-1), and the newly formed dipole is called an *induced dipole.*

Taken together, these two events lead to an intermolecular force of attraction (Fig. 12-2). We can call this an instantaneous dipole–induced dipole attraction, but the names more commonly used are **dispersion force** and **London force**. (In 1928, Fritz London offered a theoretical explanation of these forces.)

Polarizability is the term used to describe the relative tendency for a charge distribution to distort from its normal shape in an atom or a molecule. The greater this tendency, the more polarizable an atom or a molecule is said to be. Polarizability increases with atomic or molecular size (see the table on the next page), which is defined by the volume of the electron cloud around a substance. Also, in large molecules, some electrons, being farther from atomic nuclei, are less firmly held. These electrons are more easily displaced, and the polarizability

▲ FIGURE 12-1
The phenomenon of induction
The attraction of a balloon to a surface is a commonplace example of induction. The balloon is charged by rubbing, and the charged balloon induces an opposite charge on the surface. (See also Appendix B.)



▲ FIGURE 12-2
Instantaneous and induced dipoles
(a) In the *normal condition*, a nonpolar molecule has a symmetrical charge distribution. **(b)** In the *instantaneous condition*, a displacement of the electronic charge produces an instantaneous dipole with a charge separation represented as $\delta+$ and $\delta-$. **(c)** In an *induced dipole*, the instantaneous dipole on the left induces a charge separation in the molecule on the right. The result is an instantaneous dipole–induced dipole attraction.

KEEP IN MIND

that a bond dipole results from the separation of centers of positive and negative charge in a covalent bond, that a resultant dipole moment, μ, is a summation of bond dipoles taking into account their magnitudes and directions, and that a *polar* molecule (Section 10-7) is one that has a permanent resultant dipole moment.

Compound	Polarizability,* 10^{-25} cm^3	Molar Mass, amu	Boiling Point, K
H_2	7.90	2.0158	20.35
O_2	16.0	31.9988	90.19
N_2	17.6	28.0134	77.35
CH_4	26.0	16.04	109.15
C_2H_6	44.7	30.07	184.55
Cl_2	46.1	70.906	238.25
C_3H_8	62.9	44.11	231.05
CCl_4	105	153.81	349.95

*Sometimes polarizability is referred to as *polarizability volume.* Note that the units of polarizability given above have the units of volume. That provides a measure of the atomic or molecular volume.

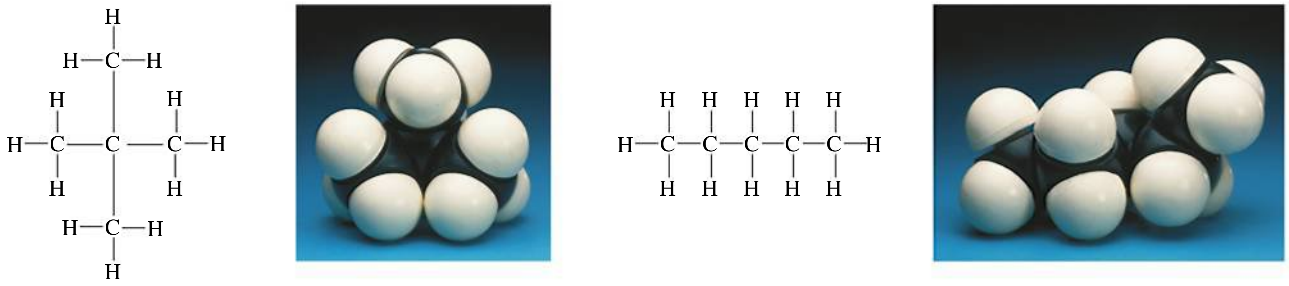
of the molecule increases. Because dispersion forces become stronger (more attractive) as polarizability increases, and because polarizability generally increases with molecular mass, the melting points and boiling points of molecular substances generally increase with increasing molecular mass. For instance, helium (atomic mass, 4 u) has a boiling point of 4 K, whereas radon (atomic mass, 222 u) has a boiling point of 211 K. The melting points and boiling points of the halogens increase in a similar way in the series F_2, Cl_2, Br_2, I_2 (recall Table 9.5).

▶ Recall from Chapter 3, a molecular substance is made up of molecules. The molecules interact with each other through relatively weak intermolecular forces. The atoms of a given molecule are held together by relatively strong covalent bonds.

The strength of dispersion forces also depends on *molecular shape.* Electrons in elongated molecules are more easily displaced than are those in small, compact, symmetrical molecules; the elongated molecules are more polarizable. Two substances with identical numbers and kinds of atoms but different molecular shapes (*isomers*) may have different properties. This idea is illustrated in Figure 12-3.

Dipole–Dipole Interactions

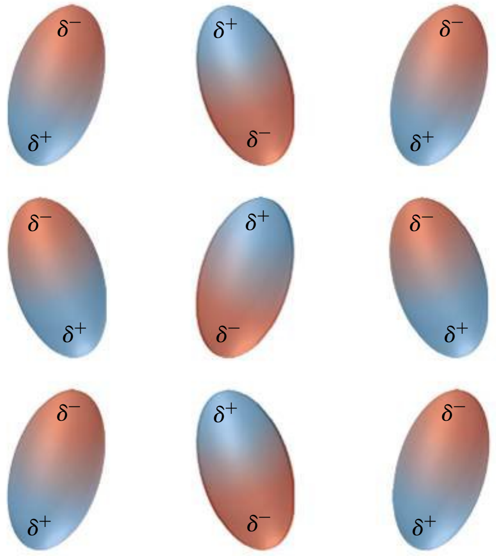
In a *polar* substance, the molecules have permanent dipole moments, so the molecules tend to line up with the positive end of one dipole directed toward the negative ends of neighboring dipoles (Fig. 12-4). This additional partial ordering of molecules can cause a substance to persist as a solid or liquid at temperatures higher than otherwise expected. Consider N_2, O_2, and NO. There are no electronegativity differences in N_2 and O_2, and both substances are nonpolar. In NO, conversely, there is an electronegativity difference, and the molecule has a slight dipole moment. Considering only dispersion forces, we would expect the boiling point of $NO(l)$ to be intermediate to those of $N_2(l)$ and $O_2(l)$, but in the comparison on the next page, we see that it is not. $NO(l)$ has the highest boiling point of the three because of its additional permanent dipole.



(a) Neopentane
bp = 9.5 °C

(b) Pentane
bp = 36.1 °C

▲ FIGURE 12-3
Molecular shapes and polarizability
The elongated pentane molecule is more polarized than is the compact neopentane molecule. Intermolecular forces are stronger in pentane than they are in neopentane. As a result, pentane boils at a higher temperature than neopentane.



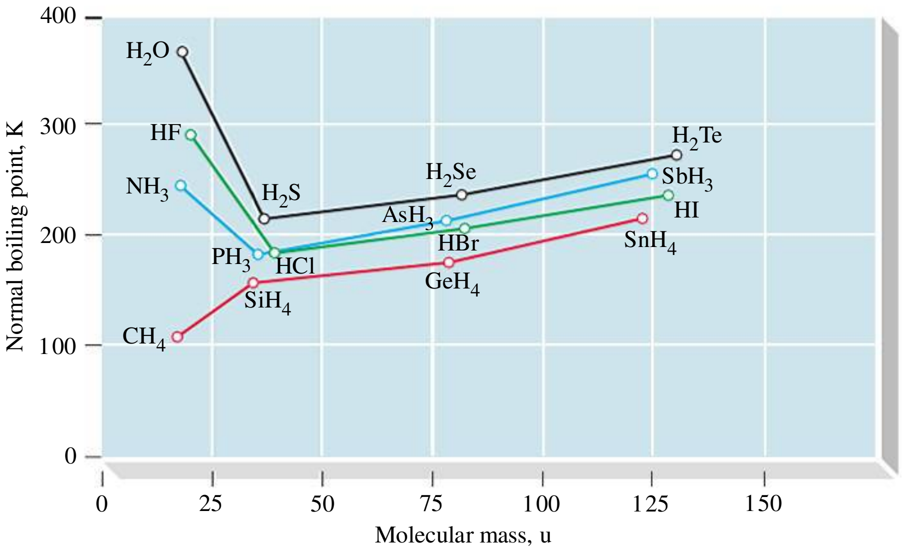
◀ FIGURE 12-4
Dipole–dipole interactions
Dipoles tend to arrange themselves with the positive end of one dipole pointed toward the negative end of a neighboring dipole. Ordinarily, thermal motion upsets this orderly array. Nevertheless, this tendency for dipoles to align themselves can affect physical properties, such as the melting points of solids and the boiling points of liquids.

N_2	NO	O_2
$\mu = 0$ (nonpolar) mol. mass $= 28$ u bp $= 77.34$ K	$\mu = 0.153$ D (polar) mol. mass $= 30$ u bp $= 121.39$ K	$\mu = 0$ (nonpolar) mol. mass $= 32$ u bp $= 90.19$ K

◀ The SI unit for dipole moment, C m, is inconvenient for expressing molecular dipole moments. The non-SI unit, debye (D), is often used. One debye is approximately 3.34×10^{-30} C m.

Hydrogen Bonding

Figure 12-5, in which the boiling points of a series of similar compounds are plotted as a function of molecular mass, demonstrates some features that we cannot explain by the types of intermolecular forces considered to this point. The hydrogen compounds (hydrides) of the group 14 elements display normal behavior; that is, the boiling points increase regularly as the molecular mass increases. But there are three striking exceptions in groups 15, 16, and 17. The boiling points of NH_3, H_2O, and HF are as high or higher than those of any other hydride in their group—not lowest, as we might expect. A special type of intermolecular force



▲ FIGURE 12-5
Comparison of boiling points of some hydrides of the elements of groups 14,15,16, and 17
The values for NH_3, H_2O, and HF are unusually high compared with those of other members of their groups.

EXAMPLE 12-1 Comparing Physical Properties of Polar and Nonpolar Substances

Which would you expect to have the higher boiling point, the hydrocarbon fuel butane, C_4H_{10}, or the organic solvent acetone, $(CH_3)_2CO$?

Analyze

Ordinarily, the first clue comes in a comparison of molecular masses. However, because the two substances have the same molecular mass (58 u), we have to look elsewhere for a factor on which to base our prediction.

The next consideration is the polarity of the molecules. The electronegativity difference between C and H is so small that we generally expect hydrocarbons, such as butane, to be nonpolar. However, we notice that one of the molecules contains a carbon-oxygen bond, and thus, a strong carbon-to-oxygen dipole. At times, it is helpful to sketch the structure of a molecule to see whether symmetrical features cause bond dipoles to cancel. It is not necessary to sketch the structure of the acetone molecule to deduce that it is a polar molecule. The $C{=}O$ bond dipole in acetone cannot be offset by other bond dipoles. Thus, acetone is polar.

Solve

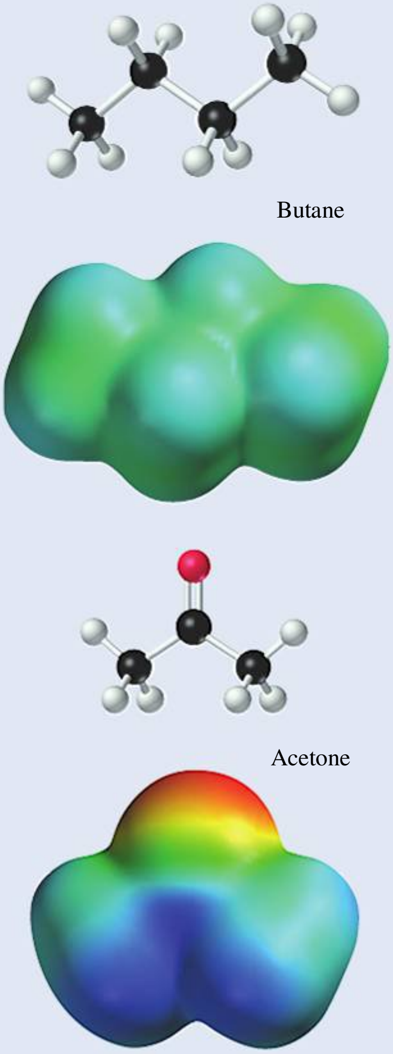
Given two substances with the same molecular mass, one polar and one nonpolar, we expect the polar substance—acetone—to have the higher boiling point. (The measured boiling points are butane, −0.5 °C; acetone, 56.2 °C.)

Assess

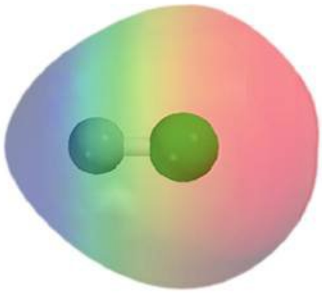
In general, when comparing the properties of different substances, we must consider the various types of intermolecular forces and the factors that affect the strength of each type of force. Although it wasn't important here, the three-dimensional shape of a molecule is usually a very important consideration and it is usually necessary to sketch the molecular structure to see how molecular shape plays a role.

PRACTICE EXAMPLE A: Which of the following substances would you expect to have the highest boiling point: C_3H_8, CO_2, CH_3CN? Explain.

PRACTICE EXAMPLE B: Arrange the following in the expected order of increasing boiling point: C_8H_{18}, $CH_3CH_2CH_2CH_3$, $(CH_3)_3CH$, C_6H_5CHO (octane, butane, isobutane, and benzaldehyde respectively).



▲ Butane and acetone
The lower diagrams are electrostatic potential diagrams for butane and acetone. The red color indicates regions of high negative electrostatic potential.



▲ Electrostatic potential map of HF

causes this exceptional behavior, as we see for hydrogen fluoride in Figure 12-6. The main points established in the figure are outlined below.

- The alignment of HF dipoles places an H atom between two F atoms. Because of the very small size of the H atom, the dipoles come close together and produce strong *dipole–dipole* attractions.
- Although an H atom is covalently bonded to one F atom, it is also weakly bonded to the F atom of a nearby HF molecule. This occurs through a lone pair of electrons on the F atom. Each H atom acts as a bridge between two F atoms.
- The bond angle between two F atoms bridged by an H atom (that is, the angle $F{-}HF \cdots F$) is about 180°.

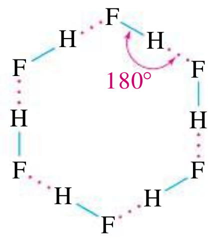
The type of intermolecular force just described is called a hydrogen bond, although it is simply an electrostatic attraction and not an actual chemical bond like a covalent bond. In a **hydrogen bond** an H atom is covalently bonded to a highly electronegative atom, which attracts electron density away from the H nucleus. This in turn allows the H nucleus, a proton, to be simultaneously attracted to a lone pair of electrons on a highly electronegative atom in a neighboring molecule.

Hydrogen bonds are possible only with certain hydrogen-containing compounds because all atoms other than H have inner-shell electrons to shield their nuclei from attraction by lone-pair electrons of nearby atoms. Only F, O, and N easily meet the requirements for hydrogen-bond formation. Weak hydrogen bonding is occasionally encountered between an H atom of one molecule and a Cl or S atom in a neighboring molecule. Compared with other intermolecular forces, hydrogen bonds are relatively strong, having energies of the order of 15 to 40 $\mathrm{kJ\,mol^{-1}}$. By contrast, single covalent bonds (also known as intramolecular bonds) are much stronger still—greater than 150 $\mathrm{kJ\,mol^{-1}}$. (See Table 10.3 for further comparisons.)

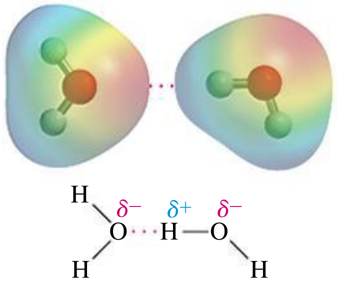
Hydrogen Bonding in Water

Ordinary water is certainly the most common substance in which hydrogen bonding occurs. Figure 12-7 shows how one water molecule is held to four neighbors in a tetrahedral arrangement by hydrogen bonds. In ice, hydrogen bonds hold the water molecules in a rigid but rather open structure. As ice melts, only a fraction of the hydrogen bonds are broken. One indication of this is the relatively low heat of fusion of ice (6.01 $\mathrm{kJ\,mol^{-1}}$). It is much less than we would expect if all the hydrogen bonds were to break during melting.

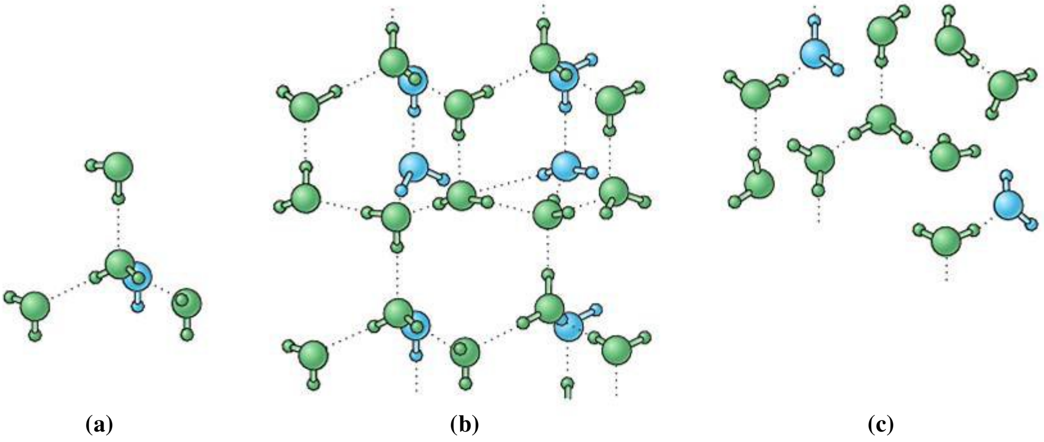
The open structure of ice shown in Figure 12-7(b) gives ice a low density. When ice melts, some of the hydrogen bonds are broken. This allows the water



▲ FIGURE 12-6
Hydrogen bonding in gaseous hydrogen fluoride
In gaseous hydrogen fluoride, many of the HF molecules are associated into cyclic $(HF)_6$ structures of the type pictured here. Each H atom is bonded to one F atom by a single covalent bond (—) and to another F atom through a hydrogen bond (···).



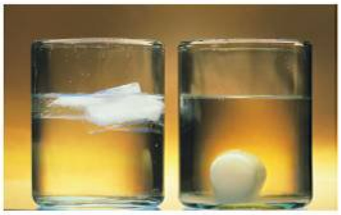
▲ **Hydrogen bonding between H_2O molecules**



▲ FIGURE 12-7
Hydrogen bonding in water
(a) Each water molecule is linked to four others through hydrogen bonds. The arrangement is tetrahedral. Each H atom is situated along a line joining two O atoms, but closer to one O atom (100 pm) than to the other (180 pm). **(b)** For the crystal structure of ice, H atoms lie between pairs of O atoms, again closer to one O atom than to the other. (Molecules behind the plane of the page are light blue.) O atoms are arranged in bent hexagonal rings arranged in layers. This characteristic pattern is similar to the hexagonal shapes of snowflakes. **(c)** In the liquid, water molecules have hydrogen bonds to only some of their neighbours. This allows the water molecules to pack more densely in the liquid than in the solid.

molecules to be more compactly arranged, accounting for the increase in density when ice melts. That is, the number of H_2O molecules per unit volume is greater in the liquid than in the solid.

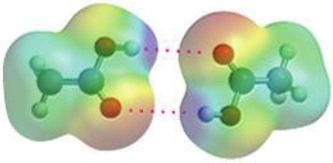
As liquid water is heated above the melting point, hydrogen bonds continue to break. The molecules become even more closely packed, and the density of the liquid water continues to increase. Liquid water attains its maximum density at 3.98 °C. Above this temperature, the water behaves in a "normal" fashion: Its density decreases as temperature increases. The unusual freezing-point behavior of water explains why a freshwater lake freezes from the top down. When the water temperature falls below 4 °C, the denser water sinks to the bottom of the lake and the colder surface water freezes. The ice over the top of the lake then tends to insulate the water below from further heat loss. This allows fish to survive the winter in a lake that has been frozen over. Without hydrogen bonding, all lakes would freeze from the bottom up; and fish, small bottom-feeding animals, and aquatic plants would not survive the winter. The density relationship between liquid water and ice is compared in Figure 12-8 with the more common liquid–solid density relationship.



▲ FIGURE 12-8
Solid and liquid densities compared
The sight of ice cubes floating on liquid water (left) is a familiar one; ice is less dense than liquid water. The more common situation, however, is that of paraffin wax (right). Solid paraffin is denser than the liquid and sinks to the bottom of the beaker.

Other Properties Affected by Hydrogen Bonding

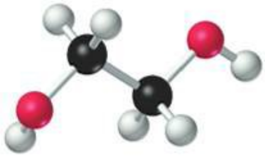
Water is one example of a substance whose properties are affected by hydrogen bonding. There are numerous others. In acetic acid, CH_3COOH, pairs of molecules tend to join together into *dimers* (double molecules), both in the liquid and in the vapor states (Fig. 12-9). Not all the hydrogen bonds are disrupted when liquid acetic acid vaporizes, and, as a result, the heat of vaporization is abnormally low.



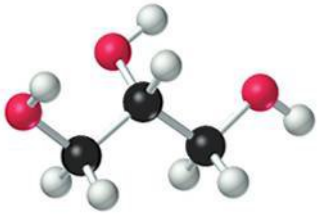
▲ FIGURE 12-9
An acetic acid dimer
Electrostatic potential maps showing hydrogen bonding.

Certain trends in viscosity can also be explained by hydrogen bonding. In alcohols, the H atom in a —OH group in one molecule can form a hydrogen bond to the O atom in a neighboring alcohol molecule. An alcohol molecule with two —OH groups (a *diol*) has more possibilities for hydrogen-bond formation than a comparable alcohol with a single —OH group. Having stronger intermolecular forces, we expect the diol to flow more slowly, that is, to have a greater viscosity, than the simple alcohol. When still more —OH groups are present (*polyols*), we expect a further increase in viscosity. These comparisons are illustrated by the three common alcohols below. (The unit cP is a centipoise. The SI unit of viscosity is $1\ \mathrm{N\ s\ m^{-2}} = 10\ \mathrm{P}$. The Greek letter eta, η, is typically used as a symbol for viscosity.)

Ethyl alcohol
(ethanol)
at 20 °C: $\eta = 1.20$ cP



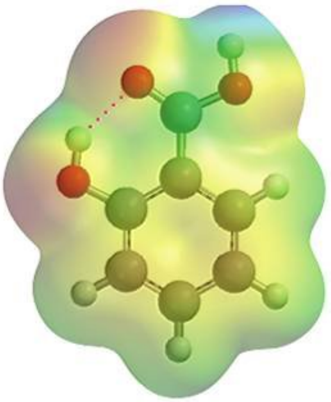
Ethylene glycol
(1,2-ethanediol)
at 20 °C: $\eta = 19.9$ cP



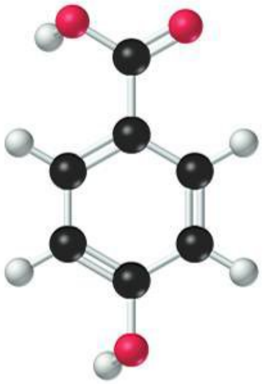
Glycerol
(1,2,3-propanetriol)
at 20 °C: $\eta = 1490$ cP

*Inter*molecular and *Intra*molecular Hydrogen Bonding

All the examples of hydrogen bonding presented to this point have involved an intermolecular force *between two molecules*, and this is called an *intermolecular hydrogen bond*. Another possibility occurs in molecules with an H atom covalently bonded to one highly electronegative atom (for example, O or N) and with another highly electronegative atom nearby in the same molecule. This type of hydrogen bonding *within a molecule* is called *intramolecular hydrogen bonding*. As shown in the molecular model of salicylic acid on the facing page, an intramolecular hydrogen bond (represented by a dotted line) joins the —OH group to the doubly bonded oxygen atom of the —COOH group on the same molecule. To underscore the importance of molecular geometry in establishing the conditions necessary for intramolecular hydrogen bonding, we need only turn to an isomer of salicylic acid called *para*-hydroxybenzoic acid. In this molecule, the H atom of the —COOH group is too close to the doubly bonded O atom of the same group to form a hydrogen bond, and the H atom of the —OH group on the opposite side of the molecule is too far away. Intramolecular hydrogen bonding does not occur in this situation.



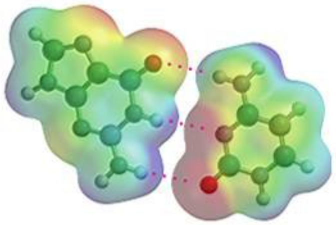
▲ Electrostatic potential map of salicylic acid showing intramolecular hydrogen bonding. The double bond character of certain bonds are not shown in the ball-and-stick model.



▲ There is no intramolecular hydrogen bonding in *para*-hydroxybenzoic acid.

Hydrogen Bonding In Living Matter

Some chemical reactions in living matter involve complex structures, such as proteins and DNA, and in these reactions certain bonds must be easily broken and re-formed. Hydrogen bonding is the only type of bonding with energies of just the right magnitude to allow this, as we will discover in Chapter 27. We will also find that both intra- and intermolecular hydrogen bonding is involved in these complex structures.



▲ Hydrogen bonding between guanine (left) and cytosine(right)in DNA

Hydrogen bonding seems to provide an answer to the puzzle of how some trees are able to grow to great heights. In Chapter 6 (page 181), we learned that atmospheric pressure is capable of pushing a column of water to a maximum height of only about 10 m—other factors must be involved in transporting water to the tops of redwood trees up to 100 m tall. Hydrogen bonding seems to be a factor in transporting water in trees. Thin columns of water (in xylem, a plant tissue) extend from the roots to the leaves in the very tops of trees. In these columns, the water molecules are hydrogen-bonded to one another, with each water molecule acting like a link in a cohesive chain. When one water molecule evaporates from a leaf, another molecule in the chain moves to take its place and all the other molecules are pulled up the chain. Ultimately, a new water molecule joins the chain in the root system. In the next chapter, we will learn about another factor in transporting water in trees: osmotic pressure and its ability to force water through a membrane.

▲ Sequoia trees
The mystery of how these trees can bring water to leaves that are hundreds of feet up may be explained by hydrogen bonding.

12-1 CONCEPT ASSESSMENT

What are the types of intermolecular interactions in $CH_3CH_2NH_2(l)$, and which is the strongest?

TABLE 12.1 Intermolecular Forces and Properties of Selected Substances

	Molecular Mass, u	Dipole Moment, D	Van der Waals Forces		ΔH_{vap}, kJ mol^{-1}	Boiling Point, K
			% Dispersion	% Dipole		
F_2	38.00	0	100	0	6.86	85.01
HCl	36.46	1.08	81.4	18.6	16.15	188.11
HBr	80.92	0.82	94.5	5.5	17.61	206.43
HI	127.91	0.44	99.5	0.5	19.77	237.80

Summary of van der Waals Forces

When assessing the importance of van der Waals forces, consider the following statements.

- *Dispersion (London) forces exist between all molecules.* They involve displacements of all the electrons in molecules, and they increase in strength with increasing molecular mass. The forces also depend on molecular shapes.
- *Forces associated with permanent dipoles* involve displacements of electron pairs in bonds rather than in molecules as a whole. These forces are found only in substances with resultant dipole moments (polar molecules). Their existence *adds* to the effect of dispersion forces also present.
- *When comparing substances of roughly comparable molecular masses,* dipole forces can produce significant differences in properties such as melting point, boiling point, and enthalpy of vaporization.
- *When comparing substances of widely different molecular masses,* dispersion forces are usually more significant than dipole forces.

▶ In our discussion of London forces, we use molar mass only as a guide to the number of electrons present in a molecule; the forces holding a molecule in a liquid are not gravitational in nature.

Let's see how these statements relate to the data in Table 12.1, which includes a rough breakdown of van der Waals forces into dispersion forces and forces caused by dipoles. HCl and F_2 have comparable molecular masses, but because HCl is polar, it has a significantly larger ΔH_{vap} and a higher boiling point. Within the series HCl, HBr, and HI, molecular mass increases sharply and ΔH_{vap} and boiling points increase in the order HCl $<$ HBr $<$ HI. The more polar nature of HCl and HBr relative to HI is not sufficient to reverse the trends produced by the increasing molecular masses—dispersion forces are the predominant intermolecular forces.

12-1 ARE YOU WONDERING...

Are there other types of intermolecular forces?

There are other types of intermolecular forces in addition to London dispersion, dipole–dipole, and hydrogen bonding. Table 12.2 summarizes some of the more commonly encountered intermolecular forces, along with their typical strengths.

In Table 12.2 one of the strongest forces between ions or molecules arises from the electrostatic attraction of opposite charge (ion–ion). This type of intermolecular force is what gives rise to the high melting points of ionic solids, along with their brittle nature. In such molecules as biomolecules, interactions between different charged groups, also known as salt bridges, increase their stability.

As we discovered in Chapter 11 molecules have dipole moments because of electronegativity differences between atoms. The dipole moment in a molecule will interact with a charged ion to form an ion–dipole interaction. Ion–dipole interactions are important in understanding the dissolution of salts.

In the absence of charges and dipole moments, other higher-order moments (e.g., quadrupole moments) become dominant. An example of quadrupole–quadrupole interactions would be between two CO_2 molecules.

KEEP IN MIND

that the term *intermolecular forces* is used to classify a specific set of noncovalent interactions.

TABLE 12.2 Summary of Noncovalent Interactions

Force	Energy,[a] kJ/mol	Example	Model
Intermolecular			
London dispersion	0.05–40	$CH_4 \cdots CH_4$	
Dipole–induced dipole	2–10	$CH_3(CO)CH_3 \ldots CH_5H_{12}$	Ion–induced dipole	3–15	$Li^+ \ldots C_5H_{12}$	Dipole–dipole	5–25	$H_2O \ldots CO$	Hydrogen bond	10–40	$CH_3OH \ldots H_2O$	Ion–dipole	40–600	$K^+ \ldots H_2O$	Ion–ion	400–4000	$Lys^+ \ldots Glu^-$	Interatomic			
London dispersion	0.05–40	Ar . . . Ar	
Ion–ion	400–4000	$Na^+ \ldots Cl^-$	Metallic	100–1000	Ag . . . Ag	
---

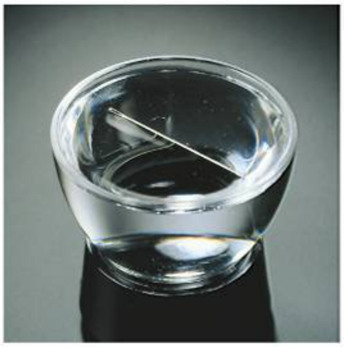
12-2 Some Properties of Liquids

Surface Tension

The observation of a needle floating on water, as pictured in Figure 12-10, is puzzling. Steel is much denser than water and should not float. Something must overcome the force of gravity on the needle, allowing it to remain suspended on the surface of the water. What is this special quality associated with the surface of liquid water?



▲ FIGURE 12-10
An effect of surface tension illustrated
Despite being denser than water, the needle is supported on the surface of the water. The property of surface tension accounts for this unexpected behaviour.

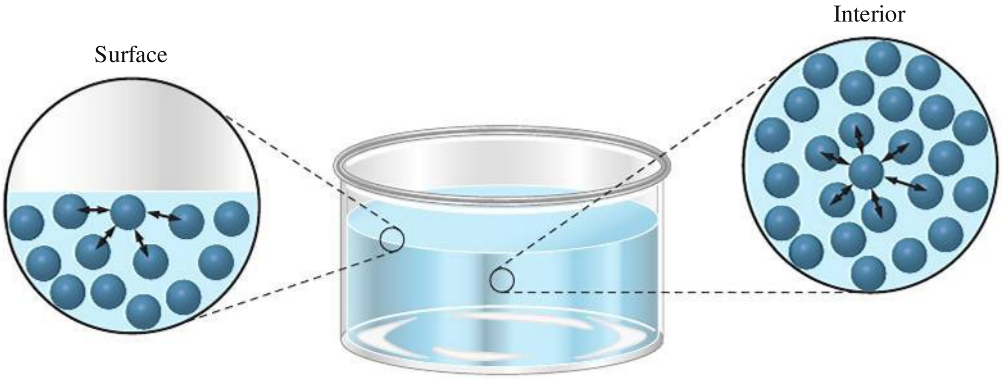
▶ The surface tension of water at 20 °C, for example, is $7.28 \times 10^{-2}\ \text{J m}^{-2}$, and that of mercury is more than six times as large, at $47.2 \times 10^{-2}\ \text{J m}^{-2}$.

Figure 12-11 suggests an important difference in the forces experienced by molecules within the bulk of a liquid and by those at the surface. Interior molecules have more neighbors and experience more attractive intermolecular interactions than surface molecules. The increased number of attractions by neighboring molecules places an interior molecule in a more stable environment (lower energy state) than a surface molecule. Consequently, as many molecules as possible tend to enter the bulk of a liquid, while as few as possible remain at the surface. Thus, liquids tend to maintain a minimum surface area. To increase the surface area of a liquid requires that molecules be moved from the interior to the surface of a liquid, and this requires that work be done. The steel needle of Figure 12-10 remains suspended on the surface of the water because energy is required to spread the surface of the water over the top of the needle.

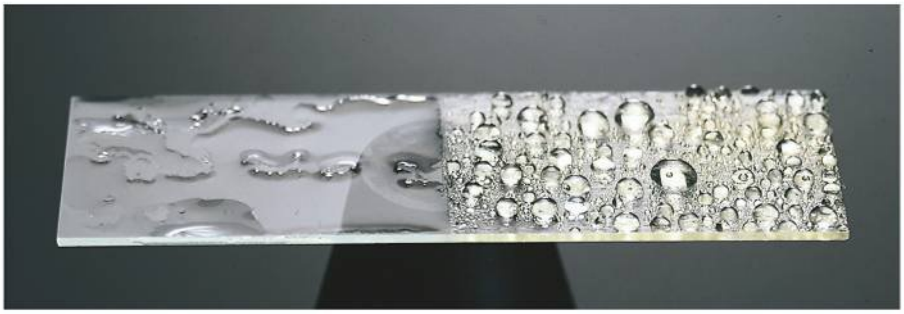
Surface tension is the energy, or work, required to increase the surface area of a liquid. Surface tension is often represented by the Greek letter gamma (γ) and has the units of energy per unit area, typically joules per square meter (J m^{-2}). As the temperature—and hence the intensity of molecular motion—increases, intermolecular forces become less effective. Less work is required to extend the surface of a liquid, meaning that surface tension *decreases* with *increased* temperature.

When a drop of liquid spreads into a film across a surface, we say that the liquid *wets* the surface. Whether a drop of liquid wets a surface or retains its spherical shape and stands on the surface depends on the strengths of two types of intermolecular forces. The forces exerted between molecules holding them together in the drop are **cohesive forces**, and the forces between liquid molecules and the surface are **adhesive forces**. If cohesive forces are strong compared with adhesive forces, a drop maintains its shape. If adhesive forces are strong enough, the energy requirement for spreading the drop into a film is met through the work done by the collapsing drop.

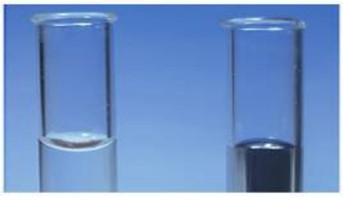
Water wets many surfaces, such as glass and certain fabrics. This characteristic is essential to its use as a cleaning agent. If glass is coated with a film of oil



▲ FIGURE 12-11
Intermolecular forces in a liquid
Molecules at the surface are attracted only by other surface molecules and by molecules below the surface. Molecules in the interior experience forces from neighbouring molecules in all directions.



▲ FIGURE 12-12
Wetting of a surface
Water spreads into a thin film on a clean glass surface (left). If the glass is coated with oil or grease, the adhesive forces between the water and oil are not strong enough to spread the water, and droplets stand on the surface (right).

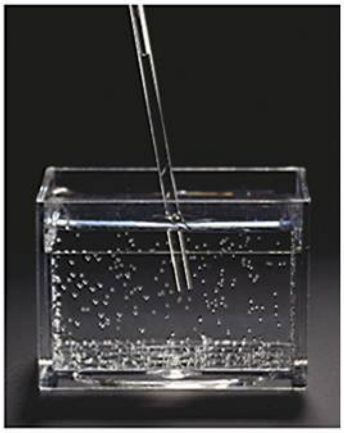


▲ FIGURE 12-13
Meniscus formation
Water wets glass (left). The meniscus is concave—the bottom of the meniscus is below the level of the water–glass contact line. Mercury does not wet glass. The meniscus is convex—the top of the meniscus is above the mercury–glass contact line.

or grease, water no longer wets the surface and water droplets stand on the glass, as shown in Figure 12-12. When we clean glassware in the laboratory, we have done a good job if water forms a uniform thin film on the glass. When we wax a car, we have done a good job if water uniformly beads up all along the surface.

Adding a detergent to water has two effects: The detergent solution dissolves grease to expose a clean surface, and the detergent lowers the surface tension of water. Lowering the surface tension means lowering the energy required to spread drops into a film. Substances that reduce the surface tension of water and allow it to spread more easily are known as *wetting agents*. They are used in applications ranging from dish washing to industrial processes.

Figure 12-13 illustrates another familiar observation. If the liquid in the glass tube is water, the water is drawn slightly up the walls of the tube by adhesive forces between water and glass. The interface between the water and the air above it, called a *meniscus*, is concave, or curved in. With liquid mercury, the meniscus is convex, or curved out. Cohesive forces in mercury, consisting of metallic bonds between Hg atoms, are strong; mercury does not wet glass. The effect of meniscus formation is greatly magnified in tubes of small diameter, called *capillary tubes*. In the *capillary action* shown in Figure 12-14, the water level inside the capillary tube is noticeably higher than outside. The soaking action of a sponge depends on the rise of water into capillaries of a fibrous material, such as cellulose. The penetration of water into soils also depends in part on capillary action. Conversely, mercury—with its strong cohesive forces and weaker adhesive forces—does not show a capillary rise. Rather, mercury in a glass capillary tube will have a lower level than the mercury outside the capillary.



▲ FIGURE 12-14
Capillary action
A thin film of water spreads up the inside walls of the capillary because of strong adhesive forces between water and glass (water wets glass). The pressure below the meniscus falls slightly. Atmospheric pressure then pushes a column of water up the tube to eliminate the pressure difference. The *smaller* the diameter of the capillary, the *higher* the liquid rises. Because its magnitude is also directly proportional to surface tension, capillary rise provides a simple experimental method of determining surface tension, described in Exercise 119.

Viscosity

Another property at least partly related to intermolecular forces is **viscosity**—a liquid's resistance to flow. The stronger the intermolecular forces of attraction, the greater the viscosity. When a liquid flows, one portion of the liquid moves with respect to neighboring portions. Cohesive forces within the liquid create an internal friction, which reduces the rate of flow. In liquids of low viscosity, such as ethyl alcohol and water, the effect is weak, and they flow easily. Liquids such as honey and heavy motor oil flow much more sluggishly. We say that they are *viscous*. One method of measuring viscosity is to time the fall of a steel ball through a certain depth of liquid (Fig. 12-15). The greater the viscosity of the liquid, the longer it takes for the ball to fall. Because intermolecular forces of attraction can be offset by higher molecular kinetic energies, viscosity generally *decreases* with *increased* temperature for liquids.

◀ For liquids, viscosity decreases with increasing temperature, but for gases, the viscosity increases with increasing temperature.

▲ FIGURE 12-15
Measuring Viscocity
By measuring the velocity of a ball dropping through a liquid, a measure of the liquid viscosity can be obtained.

12-2 CONCEPT ASSESSMENT

The viscosity of automotive motor oil is designated by its SAE number, such as 40 W. When compared in a ball viscometer (Fig. 12-15), the ball drops much faster through 10 W oil than through 40 W oil. Which of these two oils provides better winter service in the Arctic region of Canada? Which is best suited for summer use in the American Southwest? Which oil has the stronger intermolecular forces of attraction?

Enthalpy of Vaporization

In our study of the kinetic-molecular theory (Section 6-7), we saw that the speeds and kinetic energies of molecules vary over a wide range at any given temperature (Fig. 6-16). Then, in Chapter 7, we learned that molecules having kinetic energies sufficiently above the average value are able to overcome intermolecular forces of attraction and escape from the surface of the liquid into the gaseous state. This passage of molecules from the surface of a liquid into the gaseous, or vapor, state is called **vaporization** or **evaporation**. Vaporization occurs more readily with

- *increased temperature*—more molecules have sufficient kinetic energy to overcome intermolecular forces of attraction in the liquid.
- *increased surface area* of the liquid—a greater proportion of the liquid molecules are at the surface.
- *decreased strength of intermolecular forces*—the kinetic energy needed to overcome intermolecular forces of attraction is less, and more molecules have enough energy to escape.

Because the molecules lost through evaporation are much more energetic than average, the average kinetic energy of the remaining molecules decreases. The temperature of the evaporating liquid falls. This accounts for the cooling sensation you feel when a volatile liquid, such as ethyl alcohol, evaporates on your skin.

To vaporize a liquid at constant temperature, we must replace the excess kinetic energy carried away by the vaporizing molecules by adding heat to the liquid. The *enthalpy of vaporization* is the quantity of heat that must be absorbed if a certain quantity of liquid is vaporized at a constant temperature. Stated in another way,

$$\Delta H_{\text{vaporization}} = H_{\text{vapor}} - H_{\text{liquid}}$$

Because vaporization is an *endothermic* process, $\Delta H_{\text{vaporization}}$ (or ΔH_{vap} as it is more commonly denoted) is always positive. We will generally express enthalpies of vaporizations in terms of one mole of liquid vaporized, as seen in Table 12.3. The differences in enthalpies of vaporization in Table 12.3 are the result of intermolecular forces. For example, the intermolecular forces of diethyl ether are dispersion, while those of methyl alcohol are a combination of dipole and hydrogen bonding, creating the difference in their enthalpies of vaporization. Likewise, the higher dispersion in ethyl alcohol than in methyl alcohol yields a stronger interaction between ethyl alcohol's molecules and therefore

TABLE 12.3 Some Enthalpies of Vaporization at 298 K[a]

Liquid	ΔH_{vap}, kJ mol^{-1}
Diethyl ether, $(C_2H_5)_2O$	29.1
Methyl alcohol, CH_3OH	38.0
Ethyl alcohol, CH_3CH_2OH	42.6
Water, H_2O	44.0

[a] ΔH_{vap} values are somewhat temperature-dependent (see Exercise 93).

an increase in its enthalpy of vaporization. The reason that water has a much higher enthalpy of vaporization than the alcohols is that water forms four hydrogen bonds, whereas the alcohols can form only three hydrogen bonds.

The conversion of a gas or vapor to a liquid is called **condensation**. From a thermochemical standpoint, condensation is the reverse of vaporization.

$$\Delta H_{\text{condensation}} = H_{\text{liquid}} - H_{\text{vapor}} = -\Delta H_{\text{vap}}$$

Because it is opposite in sign but equal in magnitude to ΔH_{vap}, $\Delta H_{\text{condensation}}$ (ΔH_{cond}) is always negative. Condensation is an *exothermic* process. This explains why burns produced by a given mass of steam (vaporized water) are much more severe than burns produced by the same mass of hot water. Hot water burns only by releasing heat as it cools. Steam releases a large quantity of heat when it condenses to liquid water, followed by the further release of heat as the hot water cools.

KEEP IN MIND

that absolute enthalpies, such as H_{vapor} and H_{liquid}, cannot be measured (page 268). However, because enthalpy is a function of state, the difference between the absolute enthalpies has a unique value, and it *can* be measured.

EXAMPLE 12-2 Estimating the Heat Evolved in the Condensation of Steam

A 0.750 L sample of steam obtained at the normal boiling point of water was allowed to condense on a slightly cooler surface. Estimate the quantity of heat evolved. Why is the result only an estimate?

Analyze

First, let us describe the steam sample a bit more precisely. Steam is water vapor, $H_2O(g)$; and when in equilibrium with liquid water at its normal boiling point, the steam is at 1.000 atm pressure.

Solve

We are given a volume of gas (0.750 L) at a fixed temperature (100.00 °C) and pressure (1.000 atm), and so we use the ideal gas equation to calculate the number of moles of $H_2O(g)$. That is,

$$n_{H_2O} = \frac{PV}{RT} = \frac{1.000\ \text{atm} \times 0.750\ \text{L}}{0.08206\ \text{L atm mol}^{-1}\ \text{K}^{-1} \times (273.15 + 100.00)\ \text{K}}$$
$$= 0.0245\ \text{mol}$$

On a molar basis, estimate the enthalpy of condensation of the $H_2O(g)$ to be the *negative* of the value of ΔH_{vap} of H_2O given in Table 12.3, that is, $-44.0\ \text{kJ mol}^{-1}$. For the 0.0245 mol sample of steam,

$$\Delta H_{\text{cond}} = 0.0245\ \text{mol} \times (-44.0\ \text{kJ mol}^{-1}) = -1.08\text{kJ}$$

Assess

This result is only an estimate for two reasons: (1) ΔH_{cond}, like ΔH_{vap}, is temperature dependent. The value used was for 298 K, whereas it should have been for 373 K, a value that was not given. (2) The condensed liquid water was at a temperature lower than 373 K ("slightly cooler surface"). An additional small quantity of heat was liberated as the condensed steam cooled to that lower temperature.

PRACTICE EXAMPLE A: How much heat is required to vaporize a 2.35 g sample of diethyl ether at 298 K?

PRACTICE EXAMPLE B: Calculate a more accurate answer to Example 12-2 by using $\Delta H_{\text{vap}} = 40.7\ \text{kJ mol}^{-1}$ for water at 100 °C, 85.0 °C as the temperature of the surface on which the steam condenses, and $4.21\ \text{J g}^{-1}\ °\text{C}^{-1}$ as the average specific heat of $H_2O(l)$ in the temperature range 85 to 100 °C.

Vapor Pressure

Water left in an open beaker evaporates completely. A different condition results if the beaker with the water is placed in a closed container. As shown in Figure 12-16, in a container with both liquid and vapor present, vaporization and condensation occur simultaneously. If sufficient liquid is present, eventually a condition is reached in which the amount of vapor remains constant. This condition is one of *dynamic equilibrium*. Dynamic equilibrium always implies that two opposing processes are occurring simultaneously and at equal rates.

(b)
(c)

▶ FIGURE 12-16
Establishing liquid–vapor equilibrium
(a) A liquid is allowed to evaporate into a closed container. Initially, only vaporization occurs. **(b)** Condensation begins. The rate at which molecules evaporate is greater than the rate at which they condense, and the number of molecules in the vapor state continues to increase. **(c)** The rate of condensation is equal to the rate of vaporization. The number of vapor molecules remains constant over time, as does the pressure exerted by this vapor.

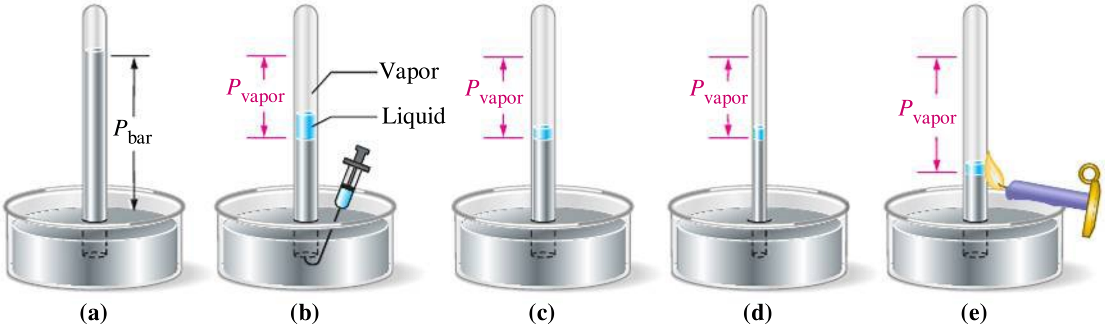
As a result, there is no net change with time once equilibrium has been established. A symbolic representation of the liquid–vapor equilibrium is shown below.

$$\text{liquid} \underset{\text{condensation}}{\overset{\text{vaporization}}{\rightleftharpoons}} \text{vapor}$$

▶ Gasoline is a mixture of volatile hydrocarbons and is an important precursor of smog, whether it is vaporized from oil refineries, filling-station operations, automobile gas tanks, or power lawn mowers.

The pressure exerted by a vapor in dynamic equilibrium with its liquid is called the **vapor pressure**. Liquids with high vapor pressures at room temperature are said to be *volatile*, and those with very low vapor pressures are *nonvolatile*. Whether a liquid is volatile or not is determined primarily by the strengths of its intermolecular forces—the weaker these forces, the more volatile the liquid (the higher its vapor pressure). Diethyl ether and acetone are volatile liquids; at 25 °C their vapor pressures are 534 and 231 mmHg, respectively. Water at ordinary temperatures is a moderately volatile liquid; at 25 °C, its vapor pressure is 23.8 mmHg. Mercury is essentially a nonvolatile liquid; at 25 °C, its vapor pressure is 0.0018 mmHg.

As an excellent first approximation, the vapor pressure of a liquid depends only on the particular liquid and its temperature. Vapor pressure depends on neither the amount of liquid nor the amount of vapor, as long as some of each is present at equilibrium. These statements are illustrated in Figure 12-17. A graph of vapor pressure as a function of temperature is known as a **vapor pressure curve**. Vapor pressure curves always have the appearance of those in Figure 12-18: *Vapor pressure increases with temperature.* Vapor pressures of water at different temperatures are presented in Table 12.4.



▲ FIGURE 12-17
Vapour pressure illustrated

Measuring Vapor Pressure

Figure 12-17 suggests one method of determining vapor pressure—inject a small sample of the target liquid at the top of a mercury barometer, and measure the depression of the mercury level. The method does not give very precise results, however, and it is not useful for measuring vapor pressures that are either very low or quite high. Better results are obtained with methods in which the pressure above a liquid is continuously varied and measured, and the liquid–vapor equilibrium temperature is recorded. In short, the boiling point of the liquid changes in accordance with the change in the pressure above the liquid, and the vapor pressure curve of the liquid can be traced. The pressure measurements are made with either a closed-end or open-end manometer (page 195). A method that is useful for determining very low vapor pressures is based on the rate of effusion of a gas through a tiny orifice. In this method, equations from the kinetic-molecular theory (Section 6-7) are applied. Example 12-3 illustrates a method (called the transpiration method) in which an inert gas is saturated with the vapor under study. Then the ideal gas equation is used to calculate the vapor pressure.

EXAMPLE 12-3 Using the Ideal Gas Equation to Calculate a Vapor Pressure

A sample of 113 L of helium gas at 1360 °C and prevailing barometric pressure is passed through molten silver at the same temperature. The gas becomes saturated with silver vapor, and the liquid silver loses 0.120 g in mass. What is the vapor pressure of liquid silver at 1360 °C?

Analyze

Let's assume that after the gas has become saturated with silver vapor, its volume remains at 113 L. This assumption will be valid if the vapor pressure of the silver is quite low compared with the barometric pressure. According to Dalton's law of partial pressures (page 213) we can deal with the silver vapor as if it were a single gas occupying a volume of 113 L.

Solve

The data required in the ideal gas equation are listed below.

$P = ?$

$R = 0.08206\ \text{L atm mol}^{-1}\ \text{K}^{-1}$

$$n = 0.120\ \text{g Ag} \times \frac{1\ \text{mol Ag}}{107.9\ \text{g Ag}} = 0.00111\ \text{mol Ag}$$

$V = 113\ \text{L}$

$T = 1360 + 273.15 = 1633\ \text{K}$

$$P = \frac{nRT}{V}$$

$$P = \frac{0.00111\ \text{mol} \times 0.08206\ \text{L atm mol}^{-1}\ \text{K}^{-1} \times 1633\ \text{K}}{113\ \text{L}}$$

$$= 1.32 \times 10^{-3}\ \text{atm}\ (1.00\ \text{Torr})$$

Assess

The assumption we made appears to be valid, because the experimental vapor pressure of liquid silver at 1360 °C is 1 mmHg or 1.32×10^{-2} atm.

PRACTICE EXAMPLE A: Equilibrium is established between liquid hexane, C_6H_{14}, and its vapor at 25.0 °C. A sample of the vapor is found to have a density of 0.701 g/L. Calculate the vapor pressure of hexane at 25.0 °C, expressed in Torr.

PRACTICE EXAMPLE B: With the help of Figure 12-18, estimate the density of the vapor in equilibrium with liquid diethyl ether at 20.0 °C.

Using Vapor Pressure Data

One use of vapor pressure data is in calculations dealing with the collection of gases over liquids, particularly water (Section 6-6). Another use, illustrated in Example 12-4, is in predicting whether a substance exists solely as a gas (vapor) or as a liquid and vapor in equilibrium.

EXAMPLE 12-4 Making Predictions with Vapor Pressure Data

As a result of a chemical reaction, 0.132 g H_2O is produced and maintained at a temperature of 50.0 °C in a closed flask of 525 mL volume. Will the water be present as liquid only, vapor only, or liquid and vapor in equilibrium (Fig. 12-19)?

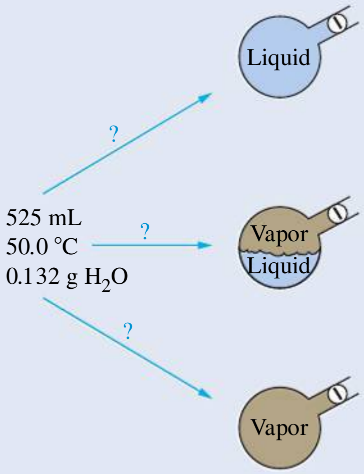
Analyze

Let's consider each of the three possibilities in the order that they are given.

Solve

LIQUID ONLY

With a density of about 1 g/mL, a 0.132 g sample of H_2O has a volume of only about 0.13 mL. There is no way that the sample could completely fill a 525 mL flask. The condition of liquid only is *impossible*.



◀ FIGURE 12-19
Predicting states of matter—Example 12.4 illustrated
For the conditions given on the left, which of the final conditions pictured on the right will result?

VAPOR ONLY

The portion of the flask that is not occupied by liquid water must be filled with something (it cannot remain a vacuum). That something is water vapor. The question is, will the sample vaporize completely, leaving no liquid? Let's use the ideal gas equation to calculate the pressure that would be exerted if the entire 0.132 g H_2O were present in the gaseous state.

$$P = \frac{nRT}{V}$$

$$= \frac{0.132\ \text{g H}_2\text{O} \times \dfrac{1\ \text{mol H}_2\text{O}}{18.02\ \text{g H}_2\text{O}} \times 0.08206\ \text{L atm mol}^{-1}\,\text{K}^{-1} \times 323.2\ \text{K}}{0.525\ \text{L}}$$

$$= 0.370\ \text{atm} \times \frac{760\ \text{mmHg}}{1\ \text{atm}} = 281\ \text{mmHg}$$

Now compare this calculated pressure with the vapor pressure of water at 50.0 °C (Table 12.4). The calculated pressure—281 mmHg—greatly exceeds the vapor pressure—92.5 mmHg. Water formed in the reaction as $H_2O(g)$ condenses to $H_2O(l)$ when the gas pressure reaches 92.5 mmHg, for this is the pressure at which the liquid and vapor are in equilibrium at 50.0 °C. The condition of vapor only is *impossible*.

LIQUID AND VAPOR

This is the only possibility for the final condition in the flask. Liquid water and water vapor coexist in equilibrium at 50.0 °C and 92.5 mmHg.

Assess

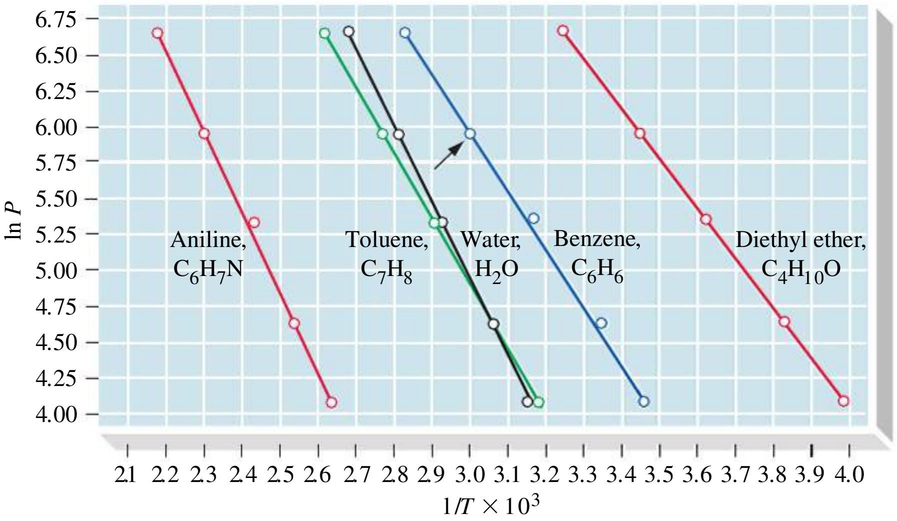
We found the solution to this problem through the application of the ideal gas equation and our understanding of vapor pressure. Note that in the first two steps, we considered the two extremes, with the first being just liquid water and the second all vapor.

PRACTICE EXAMPLE A: If the reaction described in this example resulted in H_2O produced and maintained at 80.0 °C, would the water be present as vapor only or as liquid and vapor in equilibrium? Explain.

PRACTICE EXAMPLE B: For the situation described in Example 12.4, what mass of water is present as liquid and what mass as vapor?

An Equation for Expressing Vapor Pressure Data

If you look for vapor pressure data on a liquid in a handbook or in data tables, you are unlikely to find graphs like Figure 12-18. Also, with the exception of a few liquids, such as water and mercury, you are unlikely to find data tables like Table 12.4. What you will find, instead, are mathematical equations relating vapor pressures and temperatures. Such equations can summarize in one line data that might otherwise take a full page. Equation (12.1) is a particularly common form of vapor pressure equation. It expresses the natural logarithm



▶ FIGURE 12-20
Vapor pressure data plotted as ln P versus $1/T$
Pressures are in millimeters of mercury, and temperatures are in Kelvin. Data from Figure 12-18 have been recalculated and replotted as in the following example: For benzene at 60 °C, the vapor pressure is 400 mmHg; ln P = ln 400 = 5.99. $T = 60 + 273 = 333$ K; $1/T = 1/333 = 0.00300 = 3.00 \times 10^{-3}$; $1/T \times 10^3 = 3.00 \times 10^{-3} \times 10^3 = 3.00$. The point corresponding to (3.00, 5.99) is marked by the black arrow.

(ln) of vapor pressure as a function of the reciprocal of the Kelvin temperature $(1/T)$. The relationship is that of a straight line, and the straight-line plots for the liquids featured in Figure 12-18 are drawn in Figure 12-20.

▶ Refer to Appendix A to see how the constant B is eliminated to give equation (12.2).

$$\underbrace{\ln P} = \underbrace{-A}\underbrace{\left(\frac{1}{T}\right)} \underbrace{+\,B} \qquad \textbf{(12.1)}$$

Equation of straight line: $y = m \times x + b$

To use equation (12.1), we need values for the two constants, A and B. The constant A is related to the enthalpy of vaporization of the liquid: $A = \Delta H_{vap}/R$, where ΔH_{vap} is expressed in the unit J mol^{-1} and the value used for R is 8.3145 J mol^{-1}K^{-1}. It is customary to eliminate B by rewriting equation (12.1) for two different temperatures, in a form called the Clausius–Clapeyron equation.

KEEP IN MIND

that the heat of vaporization in this equation cannot be ΔH°_{vap}, since in general the pressure is not 1 bar.

$$\ln\left(\frac{P_2}{P_1}\right) = -\frac{\Delta H_{vap}}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right) \qquad \textbf{(12.2)}$$

We apply equation (12.2) in Example 12-5.

EXAMPLE 12-5 Applying the Clausius–Clapeyron Equation

Calculate the vapor pressure of water at 35.0 °C using data from Tables 12.3 and 12.4.

Analyze

Starting with the Clausius-Clapeyron equation, we recognize that we need four pieces of data to solve for the fifth. Since we are asked to calculate a vapor pressure, we will need two temperatures, a pressure, and the enthalpy of vaporization.

Solve

Designate the unknown vapor pressure as P_1 at the temperature T_1. That is,

$$P_1 = ? \qquad T_1 = (35.0 + 273.15)\ \text{K} = 308.2\ \text{K}$$

For P_2 and T_2 choose known data for a temperature close to 35.0 °C, for example, 40.0 °C.

$$P_2 = 55.3\ \text{mmHg} \qquad T_2 = (40.0 + 273.15)\ \text{K} = 313.2\ \text{K}$$

For ΔH_{vap}, let's assume that the value given in Table 12.3 applies throughout the temperature range from 30.0 °C to 40.0 °C.

$$\Delta H_{vap} = 44.0\ \text{kJ mol}^{-1} \times \frac{1000\ \text{J}}{1\ \text{kJ}} = 44.0 \times 10^3\ \text{J mol}^{-1}$$

Now substitute these values into equation (12.2) to obtain

$$\ln\left(\frac{55.3\ \text{mmHg}}{P_1}\right) = -\frac{44.0 \times 10^3\ \text{J mol}^{-1}}{8.3145\ \text{J mol}^{-1}\ \text{K}^{-1}}\left(\frac{1}{313.2} - \frac{1}{308.2}\right)\text{K}^{-1}$$

$$= -5.29 \times 10^3(0.003193 - 0.003245) = 0.28$$

Next, determine that $e^{0.28} = 1.32$ (see Appendix A). Thus,

$$\frac{55.3\ \text{mmHg}}{P_1} = e^{0.28} = 1.32$$

$$P_1 = 55.3\ \text{mmHg}/1.32 = 41.9\ \text{mmHg}$$

Assess

Here, P_1 must be *smaller than* P_2 because $T_1 < T_2$. Thus, regardless of how we write equation (12.2)—different formulations are possible—or choose (T_1, P_1) and (T_2, P_2), we are guided by the fact that vapor pressure always increases with temperature. One way to check our answer is to repeat the calculation by using this pressure as the known pressure to see whether we obtain the pressure given in the problem. We can also check this against the experimentally determined vapor pressure of water at 35.0 °C, which is 42.175 mmHg.

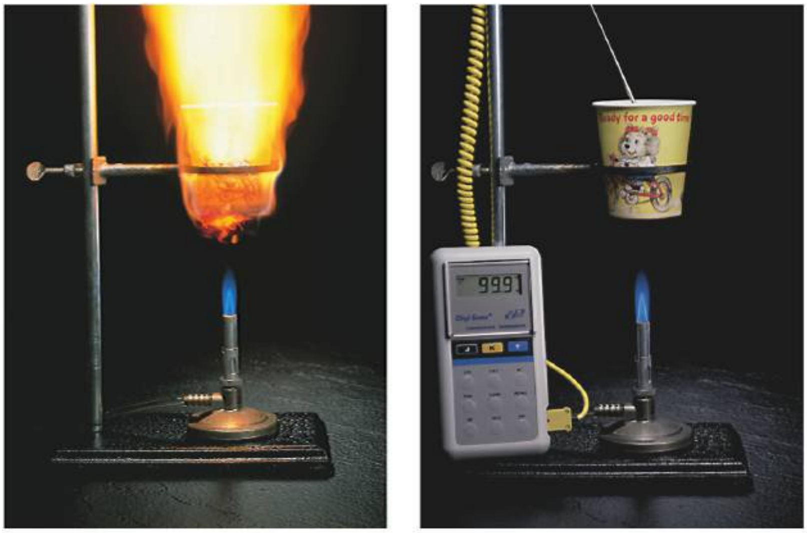
PRACTICE EXAMPLE A: A handbook lists the vapor pressure of methyl alcohol as 100 mmHg at 21.2 °C. What is its vapor pressure at 25.0 °C?

PRACTICE EXAMPLE B: A handbook lists the normal boiling point of isooctane, a gasoline component, as 99.2 °C and its enthalpy of vaporization (ΔH_{vap}) as 35.76 kJ mol^{-1} C_8H_{18}. Calculate the vapor pressure of isooctane at 25 °C.

Boiling and the Boiling Point

When a liquid is heated in a container *open to the atmosphere*, there is a particular temperature at which vaporization occurs throughout the liquid rather than simply at the surface. Vapor bubbles form within the bulk of the liquid, rise to the surface, and escape. The pressure exerted by escaping molecules equals that exerted by molecules of the atmosphere, and **boiling** is said to occur. During boiling, energy absorbed as heat is used only to convert molecules of liquid to vapor. The temperature remains constant until all the liquid has boiled away, as is dramatically illustrated in Figure 12-21. The temperature at which the vapor pressure of a liquid is equal to standard atmospheric pressure (1 atm = 760 mmHg) is the **normal boiling point**. In other words, the normal boiling point is the boiling point of a liquid at 1 atm pressure. The normal boiling points of several liquids can be determined from the intersection of the dashed line in Figure 12-18 with the vapor pressure curves for the liquids.

◀ When a pan of water is put on the stove to boil, small bubbles are usually observed as the water begins to warm. These are bubbles of dissolved air being expelled. Once the water boils, however, all the dissolved air is expelled and the bubbles consist only of water vapor.



◀ FIGURE 12-21
Bolling water in a paper cup
An empty paper cup heated over a Bunsen burner quickly bursts into flame. If a paper cup is filled with water, it can be heated for an extended time as the water boils. This is possible for three reasons: (1) Because of the high heat capacity of water, heat from the burner goes primarily into heating the water, not the cup. (2) As the water boils, large quantities of heat (ΔH_{vap}) are required to convert the liquid to its vapor. (3) The temperature of the cup does not rise above the boiling point of water as long as liquid water remains. The boiling point of 99.9 °C instead of 100.0 °C suggests that the prevailing barometric pressure was slightly below 1 atm.

Figure 12-18 also helps us see that the boiling point of a liquid varies significantly with barometric pressure. Shift the dashed line shown at $P = 760$ mmHg to higher or lower pressures, and the new points of intersection with the vapor pressure curves come at different temperatures. Barometric pressures below 1 atm are commonly encountered at high altitudes. At an altitude of 1609 m (that of Denver, Colorado), barometric pressure is about 630 mmHg. The boiling point of water at this pressure is 95 °C(203 °F). It takes longer to cook foods under conditions of lower boiling-point temperatures. A three–minute boiled egg takes longer than three minutes to cook. We can counteract the effect of high altitudes by using a pressure cooker. In a pressure cooker, the cooking water is maintained under higher-than-atmospheric pressure and its boiling temperature increases, for example, to about 120 °C at 2 atm pressure.

▶ A more extreme case is that on the summit of Mt. Everest, where a climber would barely be able to heat a cup of tea to 70 °C.

▲ **A liquid boils at low pressure**
Water boils when its vapor pressure equals the pressure on its surface. Bubbles form throughout the liquid.

12-3 CONCEPT ASSESSMENT

Why does a three-minute boiled egg take longer than three minutes to cook in Switzerland and not on Manhattan Island in New York City?

The Critical Point

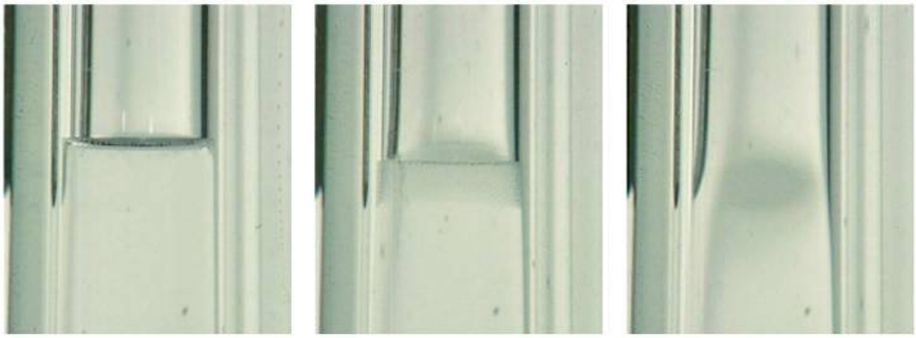
In describing boiling, we made an important qualification: Boiling occurs "in a container open to the atmosphere." If a liquid is heated in a *sealed* container, boiling does not occur. Instead, the temperature and vapor pressure rise continuously. Pressures many times atmospheric pressure may be attained. If just the right quantity of liquid is sealed in a glass tube and the tube is heated, as in Figure 12-22, the following phenomena can be observed:

- The density of the liquid decreases, that of the vapor increases, and eventually the two densities become equal.
- The surface tension of the liquid approaches zero. The interface between the liquid and vapor becomes less distinct and eventually disappears.

The **critical point** is the point at which these conditions are reached and the liquid and vapor become indistinguishable. The temperature at the critical point is the critical temperature, T_c, and the pressure is the critical pressure, P_c. The critical point is the highest point on a vapor pressure curve and represents the highest temperature at which the liquid can exist. Several critical temperatures and pressures are listed in Table 12.5.

A gas can be liquefied only at temperatures *below* its critical temperature, T_c. If room temperature is *below* T_c, this liquefaction can be accomplished just by applying sufficient pressure. If room temperature is *above* T_c, however, added pressure *and* a lowering of temperature to a value below T_c are required. We will comment further on the liquefaction of gases on page 523.

▶ Although the term *gas* can be used exclusively, sometimes the term *vapor* is used for the gaseous state at temperatures *below* T_c and gas at temperatures *above* T_c.



About 10 °C below T_c

About 1 °C below T_c

Critical temp. T_c

▶ FIGURE 12-22
Attainment of the critical point for benzene
In a sealed container, the meniscus separating a liquid from its vapor is just barely visible at the instant the critical point is reached. At the critical point—the liquid and vapor become indistinguishable.

TABLE 12.5 Some Critical Temperatures, T_c, and Critical Pressures, P_c

Substance	T_c, K	P_c, atm
"Permanent" gases[a]		
H_2	33.3	12.8
N_2	126.2	33.5
O_2	154.8	50.1
CH_4	191.1	45.8
"Nonpermanent" gases[b]		
CO_2	304.2	72.9
HCl	324.6	82.1
NH_3	405.7	112.5
SO_2	431.0	77.7
H_2O	647.3	218.3

[a] Permanent gases cannot be liquefied at 25 °C (298 K).

[b] Nonpermanent gases can be liquefied at 25 °C.

12-4 CONCEPT ASSESSMENT

Compare the critical temperatures of NH_3 and N_2 (Table 12.5). Which gas has the stronger intermolecular forces?

EXAMPLE 12-6 Relating Intermolecular Forces and Physical Properties

Arrange the following substances in the order in which you would expect their boiling points to increase: CCl_4, Cl_2, ClNO, N_2.

Analyze

Recall that boiling point trends are related to intermolecular forces. We should begin by identifying the types and strengths of intermolecular forces at work.

Solve

Three of the substances are nonpolar. For these, the strengths of dispersion forces, and hence the boiling points, should increase with increasing molecular mass, that is, $N_2 < Cl_2 < CCl_4$. ClNO has a molecular mass (65.5 u) comparable to that of Cl_2 (70.9 u), but the ClNO molecule is polar (bond angle $\approx 120°$). This suggests stronger intermolecular forces and a higher boiling point for ClNO than for Cl_2. We should not expect the boiling point of ClNO to be higher than that of CCl_4, however, because of the large difference in their molecular masses (65.5 u compared with 154 u). The expected order is $N_2 < Cl_2 < \text{ClNO} < CCl_4$. (The observed boiling points are 77.3, 239.1, 266.7, and 349.9 K, respectively.)

Assess

Even though one molecule (ClNO) is polar, it does not have the highest boiling point, indicating that dispersion forces can be stronger than dipole–dipole forces.

PRACTICE EXAMPLE A: Arrange the following in the expected order of increasing boiling point: Ne, He, $Cl_2, (CH_3)_2CO, O_2, O_3$.

PRACTICE EXAMPLE B: Following are some values of ΔH_{vap} for several liquids at their normal boiling points: H_2, 0.92 kJ mol^{-1}; CH_4, 8.16 kJ mol^{-1}; C_6H_6, 31.0 kJ mol^{-1}; CH_3NO_2, 34.0 kJ mol^{-1}. Explain the differences among these values.

12-5 CONCEPT ASSESSMENT

Explain why CCl_4 has a higher boiling point than CH_3Cl, despite the polarity of CH_3Cl.

12-3 Some Properties of Solids

We mentioned some properties of solids (for example, malleability, ductility) at the beginning of this text, and we will continue to consider additional properties. For now, we will comment on some properties that allow us to think of solids in relation to the other states of matter—liquids and gases.

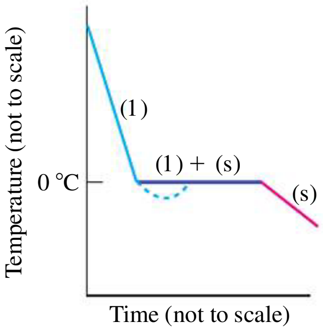
Melting, Melting Point, and Heat of Fusion

As a crystalline solid is heated, its atoms, ions, or molecules vibrate more vigorously. Eventually a temperature is reached at which these vibrations disrupt the ordered crystalline structure. The atoms, ions, or molecules can slip past one another, and the solid loses its definite shape and is converted to a liquid. This process is called **melting**, or fusion, and the temperature at which it occurs is the **melting point**. The reverse process, the conversion of a liquid to a solid, is called **freezing**, or solidification, and the temperature at which it occurs is the **freezing point**. The melting point of a solid and the freezing point of its liquid are identical. At this temperature, solid and liquid coexist in equilibrium.

If we add heat uniformly to a solid–liquid mixture at equilibrium, the temperature remains constant while the solid melts. Only when all the solid has melted does the temperature begin to rise. Conversely, if we remove heat uniformly from a solid–liquid mixture at equilibrium, the liquid freezes at a constant temperature. The quantity of heat required to melt a solid is the *enthalpy of fusion*, ΔH_{fus}. Some typical enthalpies of fusion, expressed in kilojoules per mole, are listed in Table 12.6. Perhaps the most familiar example of a melting (and freezing) point is that of water, 0 °C. This is the temperature at which liquid and solid water, in contact with air and under standard atmospheric pressure, are in equilibrium. The enthalpy of fusion of water is 6.01 kJ mol^{-1}, which we can express as

$$H_2O(s) \longrightarrow H_2O(l) \qquad \Delta H_{fus} = +6.01 \text{ kJ mol}^{-1} \qquad \textbf{(12.3)}$$

Here is an easy way to determine the freezing point of a liquid. Allow the liquid to cool, and measure the liquid temperature as it falls with time. When freezing begins, the temperature *remains constant* until all the liquid has frozen. Then the temperature is again free to fall as the solid cools. If we plot temperatures against time, we get a graph known as a *cooling curve*. Figure 12-23 is a



▲ FIGURE 12-23
Cooling curve for water
The broken-line portion represents the condition of supercooling that occasionally occurs.
(l) = liquid; (s) = solid.

TABLE 12.6 Some Enthalpies of Fusion

Substance	Melting Point, °C	ΔH_{fus}, kJ mol^{-1}
Mercury, Hg	−38.9	2.30
Sodium, Na	97.8	2.60
Methyl alcohol, CH_3OH	−97.7	3.21
Ethyl alcohol, CH_3CH_3COOH	−114	5.01
Water, H_2O	0.0	6.01

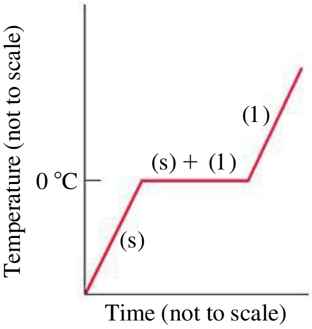
cooling curve for water. We can also run this process backward, that is, by starting with the solid and adding heat. Now the temperature remains constant while melting occurs. This temperature–time plot is called a *heating curve.* Generally speaking, the appearance of the heating curve is that of a cooling curve that has been flipped from left to right. A heating curve for water is sketched in Figure 12-24.

Often, an experimentally determined cooling curve does not look quite like the solid–line plot in Figure 12-23. The temperature may drop below the freezing point without any solid appearing. This condition is known as *supercooling.* For a crystalline solid to start forming from a liquid at the freezing point, the liquid must contain some small particles (for example, suspended dust particles) on which crystals can form. If a liquid contains a very limited number of particles on which crystals can grow, it may supercool for a time before freezing. When a supercooled liquid does begin to freeze, however, the temperature rises back to the normal freezing point while freezing is completed. We can always recognize supercooling through a slight dip in a cooling curve just before the horizontal portion.



▲ FIGURE 12-24
Heating curve for water
This curve traces the changes that occur as ice is heated from below the melting point to produce liquid water somewhat above the melting point.

◀ Examples of supercooled substances are water droplets in the sky. They remain liquid at temperatures well below the freezing point. When they find a bit of dust on which they can nucleate, the droplets spontaneously turn to ice.

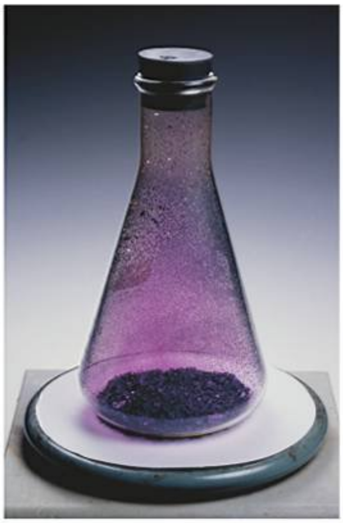
Sublimation

Like liquids, solids can also give off vapors, although because of the stronger intermolecular forces present, solids are generally not as volatile as liquids at a given temperature. The direct passage of molecules from the solid to the vapor state is called **sublimation**. The reverse process, the passage of molecules from the vapor to the solid state, is called **deposition**. When sublimation and deposition occur at equal rates, a dynamic equilibrium exists between a solid and its vapor. The vapor exerts a characteristic pressure called the *sublimation pressure.* A plot of sublimation pressure as a function of temperature is called a *sublimation curve.* The *enthalpy of sublimation* (ΔH_{sub}) is the quantity of heat needed to convert a solid to vapor. At the sublimation point, sublimation (solid $\longrightarrow$ vapor) is equivalent to melting (solid $\longrightarrow$ liquid) followed by vaporization (liquid $\longrightarrow$ vapor). This suggests the following relationship among ΔH_{fus}, ΔH_{vap}, and ΔH_{sub} at the melting point.

$$\Delta H_{sub} = \Delta H_{fus} + \Delta H_{vap} \qquad \textbf{(12.4)}$$

The value of ΔH_{sub} obtained with equation (12.4) can replace the enthalpy of vaporization in the Clausius–Clapeyron equation (12.2), so that sublimation pressures can be calculated as a function of temperature.

Two familiar solids with significant sublimation pressures are ice and dry ice (solid carbon dioxide). If you live in a cold climate, you are aware that snow may disappear from the ground even though the temperature may fail to rise above 0 °C. Under these conditions, the snow does not melt; it sublimes. The sublimation pressure of ice at 0 °C is 4.58 mmHg. That is, the solid ice has a vapor pressure of 4.58 mmHg at 0 °C. If the air is not already saturated with water vapor, the ice will sublime. The sublimation and deposition of iodine are pictured in Figure 12-25.

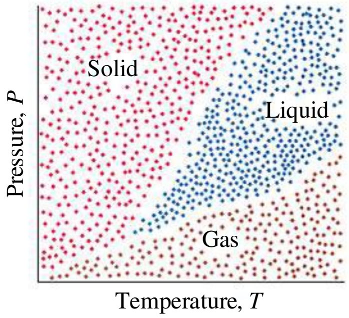


▲ FIGURE 12-25
Sublimation of iodine
Even at temperatures well below its melting point of 114 °C, solid iodine exhibits an appreciable sublimation pressure. Here, purple iodine vapor is produced at about 70 °C. Deposition of the vapor to solid iodine occurs on the colder walls of the flask.

12-6 CONCEPT ASSESSMENT

Recall the discussion of dew and frost formation (see the Focus On feature for Chapter 6, *Earth's Atmosphere*, at www.masteringchemistry.com). Do the surroundings absorb or lose heat when water vapor condenses to dew or frost? Is the quantity of heat per gram of $H_2O(g)$ condensed the same whether the condensate is dew or frost? Explain.

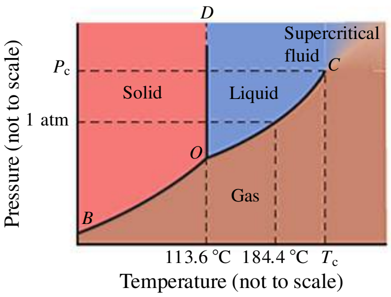
12-4 Phase Diagrams



▲ FIGURE 12-26
Temperature, pressure, and states of matter
The outline of a phase diagram is suggested by the distribution of points. The red points identify the temperatures and pressures at which solid is the stable phase; the blue points identify the temperatures and pressures at which liquid is the stable phase; and the brown points represent the temperatures and pressures at which gas is the stable phase. (See also Figures 12-27 and 12-28.)

Imagine constructing a pressure–temperature graph in which each point on the graph represents a condition under which a substance might be found. At low temperatures and high pressures, such as the red points in Figure 12-26, we expect the atoms, ions, or molecules of a substance to be in a close orderly arrangement—a solid. At high temperatures and low pressures—the brown points in Figure 12-26—we expect the gaseous state; and at intermediate temperatures and pressures, we expect a liquid (blue points in Figure 12-26).

Figure 12-26 is a **phase diagram**, a graphical representation of the conditions of temperature and pressure at which solids, liquids, and gases (vapors) exist, either as single phases, or states, of matter or as two or more phases in equilibrium with one another. The different regions of the diagram correspond to single phases, or states, of matter. Straight or curved lines where single-phase regions adjoin represent two phases in equilibrium.



▲ FIGURE 12-27
Phase diagram for iodine
Note that the melting point and triple point temperatures for iodine are essentially the same. Generally, large pressure increases are required to produce even small changes in solid–liquid equilibrium temperatures. The pressure and temperature axes on a phase diagram are generally not drawn to scale so that the significant features of the diagram can be more readily emphasized.

Iodine

One of the simplest phase diagrams is that of iodine shown in Figure 12-27. The curve *OC* is the vapor pressure curve of liquid iodine, and *C* is the critical point. *OB* is the sublimation curve of solid iodine. The nearly vertical line *OD* represents the effect of pressure on the melting point of iodine; it is called the *fusion curve.* The point *O* has a special significance. It defines the *unique* temperature and pressure at which the *three* states of matter, solid, liquid, and gas, coexist in equilibrium. It is called a **triple point**. For iodine, the triple point is at 113.6 °C and 91.6 mmHg. The normal melting point (113.6 °C) and the boiling point (184.4 °C) are the temperatures at which a line at $P = 1$ atm intersects the fusion and vapor pressure curves, respectively. Melting is essentially unaffected by pressure in the limited range from 91.6 mmHg to 1 atm, and the normal melting point and the triple point are at almost the same temperature.

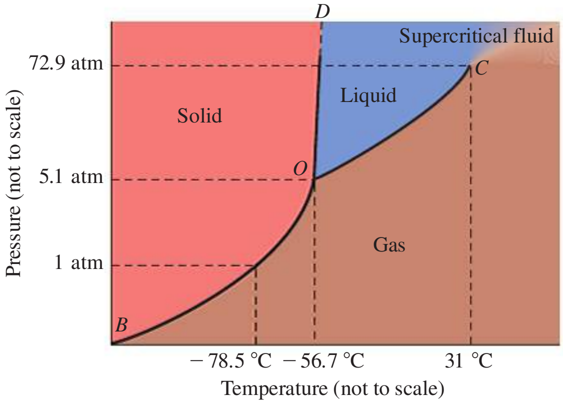
The sublimation curve for iodine in Figure 12-27 appears to be a continuation of the vapor pressure curve, but if the data are plotted to scale, a discontinuity is seen at the triple point *O*. Moreover, this must *always* be the case. If these two curves were continuous, then the lines representing the variation of ln P with $1/T$ (Fig. 12-20) would have the same slope—but this is not possible. The value of ΔH_{vap} determines the slope of the vapor pressure line (recall equation 12.1), whereas ΔH_{sub} determines the slope of the sublimation line. However, these two enthalpy changes can never be the same, because $\Delta H_{\text{sub}} = \Delta H_{\text{vap}} + \Delta H_{\text{fus}}$.

The extreme range of temperatures and pressures required for the entire phase diagram precludes plotting it to scale. This is why the axes are labeled "not to scale."

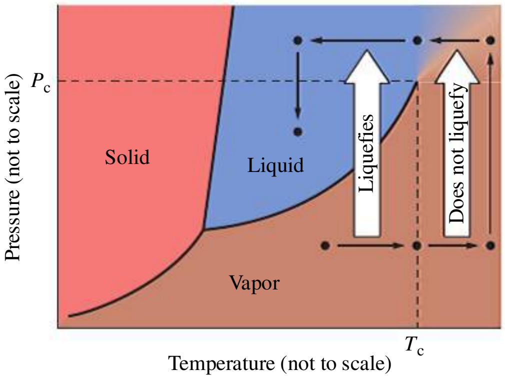
Carbon Dioxide

The case of carbon dioxide, shown in Figure 12-28, differs from that of iodine in one important respect—the pressure at the triple point *O* is greater than 1 atm. A line at $P = 1$ atm intersects the *sublimation curve,* not the vapor pressure curve. If solid CO_2 is heated in an open container, it sublimes away at a constant temperature of −78.5 °C. It *does not melt* at atmospheric pressure (and so is called "dry ice"). Because it maintains a low temperature and does not produce a liquid by melting, dry ice is widely used in freezing and preserving foods.

Liquid CO_2 can be obtained at pressures above 5.1 atm and it is most frequently encountered in CO_2 fire extinguishers. All three states of matter are involved in the action of these fire extinguishers. When the liquid CO_2 is released, most of it quickly vaporizes. The heat required for this vaporization is extracted from the remaining $CO_2(l)$, which has its temperature lowered to the point that it freezes and falls as a $CO_2(s)$ "snow." In turn, the $CO_2(s)$ quickly sublimes to $CO_2(g)$. All of this helps to quench a fire by displacing the air around the fire with a "blanket" of $CO_2(g)$ and by cooling the area somewhat.



▲ FIGURE 12-28
Phase diagram for carbon dioxide
Several aspects of this diagram are described in the text. An additional feature not shown here is the curvature of the fusion curve *OD* to the right at very high pressures, ultimately reaching temperatures above the critical temperature.



▲ FIGURE 12-29
Critical point and critical isotherm
Applying pressure to a gas at temperatures below the critical isotherm, T_c, causes a liquid to form with the appearance of a meniscus, a discontinuous phase change. Applying pressure above the critical isotherm simply increases the density of the supercritical fluid. In a path traced by the small arrows, gas changes to liquid without exhibiting a discontinuous phase transition.

Supercritical Fluids

Because the liquid and gaseous states become identical and indistinguishable at the critical point, it is difficult to know what to call the state of matter at temperatures and pressures above the critical point. For example, this state of matter has the high density of a liquid and the low viscosity of a gas. The term that is now commonly used is *supercritical fluid* (SCF). Above the critical temperature, no amount of pressure can liquefy a supercritical fluid. Consider the generic phase diagram in Figure 12-29. The path of dots starting with a vapor below the critical isotherm takes us to a low-density gas above the isotherm. When the pressure is greatly increased, we produce a supercritical fluid of much greater density. If, while the pressure exceeds the critical pressure, P_c, the temperature is reduced below the critical temperature, we obtain a liquid. Even with further reduction of pressure, the sample remains in the liquid phase. In following the path described, we have gone from a gas to a liquid without observing a liquid–gas interface. The only way to observe the liquid–vapor interface is to cross the phase boundary below the critical temperature. Note that in the present case we could observe the liquid–vapor interface by lowering the pressure on the liquid to a point on the vapor pressure curve.

Although we do not ordinarily think of liquids or solids as being soluble in gases, *volatile* liquids and solids are. The mole fraction solubility is simply the ratio of the vapor pressure (or the sublimation pressure) to the total gas pressure. And liquids and solids become much more soluble in a gas that is above its critical pressure and temperature, mostly because the density of the SCF is high and approaches that of a liquid. Molecules in supercritical fluids, being in much closer proximity than in ordinary gases, can exert strong attractive forces on the molecules of a liquid or solid solute. SCFs display solvent properties similar to ordinary liquid solvents. To vary the pressure of an SCF means to vary its density and also its solvent properties. Thus, a given SCF, such as carbon dioxide, can be made to behave like many different solvents.

Until recently, the principal method of decaffeinating coffee was to extract the caffeine with a solvent, such as methylene chloride (CH_2Cl_2). This solvent is objectionable because it is hazardous in the workplace and difficult to completely remove from the coffee. Now, supercritical fluid CO_2 is used. In one process, green coffee beans are brought into contact with CO_2 at about 90 °C and 160 to 220 atm. The caffeine content of the coffee is reduced from its

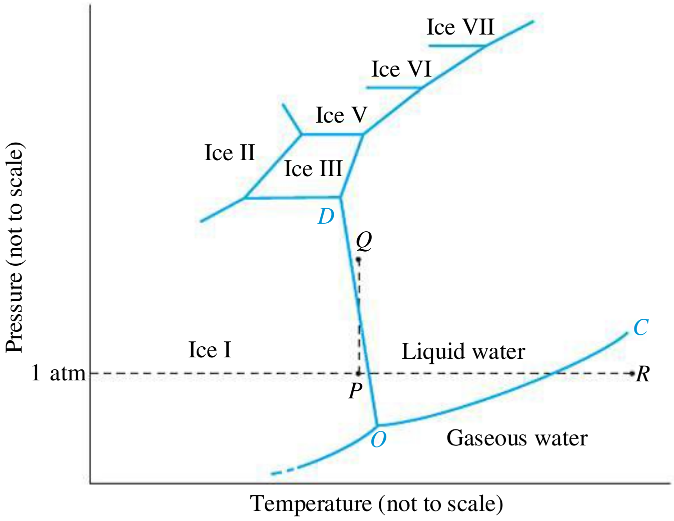
▲ **Decaffeinated coffee**
"Naturally" decaffeinated coffee is made through a process that uses supercritical fluid CO_2 as a solvent to dissolve the caffeine in green coffee beans. Afterward, the beans are roasted and sold to consumers.



▶ FIGURE 12-30
Phase diagram for water
Point *O*, the triple point, is at 0.0098 °C and 4.58 mmHg. (The normal melting point is at exactly 0 °C and 760 mmHg.) The critical point, *C*, is at 374.1 °C and 218.2 atm. At point *D* the temperature is −22.0 °C and the pressure is 2045 atm. The negative slope of the fusion curve, *OD* (greatly exaggerated here), and the significance of the broken straight lines are discussed in the text.

normal 1% to 3% to about 0.02%. When the temperature and pressure of the CO_2 are reduced, the caffeine precipitates and the CO_2 is recycled.

Water

▶ Since the L-S line in the phase diagram of water is negative, that means that ice floats. If ice did not float, then the polar seas would fill with ice that would never melt. Most solids are more dense than their liquid state. Water is, for us, a happy exception.

The phase diagram of water (Fig. 12-30) presents several new features. One is that the fusion curve *OD* has a *negative* slope; that is, it slopes toward the pressure axis. The melting point of ice *decreases* with an increase in pressure, and this is rather unusual behavior for a solid (bismuth and antimony also behave in this way). However, because large changes in pressure are required to produce even small decreases in the melting point, we do not commonly observe this melting behavior of ice. One example that has been given comes from ice-skating. Presumably, the pressure of the skate blades melts the ice, and the skater skims along on a thin lubricating film of liquid water. This explanation is unlikely, however, because the pressure of the blades doesn't produce a significant lowering of the melting point and certainly cannot explain the ability to skate on ice at temperatures much below the freezing point. (Recent experimental evidence suggests that molecules in a very thin surface layer on ice are mobile in the same way as in liquid water, and this mobility persists even at very low temperatures.)

Another feature illustrated in the phase diagram of water is **polymorphism**, the existence of a solid substance in more than one form. Ordinary ice, called ice I, exists under ordinary pressures. The other forms exist only at high pressures. Polymorphism is more the rule than the exception among solids. Where it occurs, a phase diagram has triple points in addition to the usual solid-liquid-vapor triple point. For example at point *D* in Figure 12-30, ice I, ice III, and liquid H_2O are in equilibrium at −22.0 °C and 2045 atm. Note that the fusion curves for the forms of ice other than ice I have *positive* slopes. Thus, the triple point with ice VI, ice VII, and liquid water is at 81.6 °C and 21,700 atm.

▶ An increase in pressure to 125 atm lowers the freezing point of water by only about 1 °C.

Phases and Phase Transitions

What's the difference between a phase and a state of matter? These terms tend to be used synonymously, but there is a small distinction between them. As we have already noted, there are just *three* states of matter: solid, liquid, and gas. A *phase* is any sample of matter with definite composition and uniform properties that is distinguishable from other phases with which it is in contact. Thus, we can describe liquid water in equilibrium with its vapor as a two-phase mixture. The liquid is one phase and the gas, or vapor, is the other. In this case, the phases (liquid and gas) are the same as the states of matter present (liquid and gas).

We can describe the equilibrium mixture at the triple point *D* in Figure 12-30 as a *three-phase* mixture, even though only *two* states of matter are present (solid and liquid). Two of the phases are in the solid state—the polymorphic forms ice I and ice III. For mixtures of two or more components, different phases may exist in the liquid state as well as in the solid state. For example, most mixtures of triethylamine, $N(CH_2CH_3)_3$, and water at 25 °C separate into two physically distinct liquid phases. One is a saturated solution of triethylamine in water and the other, a saturated solution of water in triethylamine. Because the pressure–temperature diagrams we have been describing can accommodate all the phases in a system, we call them *phase* diagrams. We call the crossing of a two-phase curve in a phase diagram a *phase transition*.

Listed below are six common names assigned to phase transitions.

melting $(s \longrightarrow l)$	freezing $(l \longrightarrow s)$
vaporization $(l \longrightarrow g)$	condensation $(g \longrightarrow l)$
sublimation $(s \longrightarrow g)$	deposition $(g \longrightarrow s)$

Following are two useful generalizations about the changes that occur when crossing a two-phase equilibrium curve in a phase diagram.

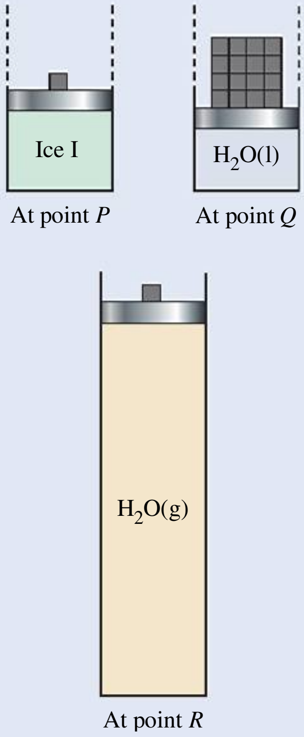
- From lower to higher temperatures along a *constant-pressure* line (an isobar), enthalpy *increases*. (Heat is absorbed.)
- From lower to higher pressures along a *constant-temperature* line (an isotherm), volume *decreases*. (The phase at the higher pressure has the higher density.)

The second generalization helps us to understand why a fusion curve usually has a positive slope. Typical behavior is for a solid to have a greater density than the corresponding liquid. Example 12-7 illustrates how we can use a phase diagram to describe the phase transitions that a substance can undergo.

◀ Because ice I is less dense than $H_2O(l)$, the fusion curve *OD* in Figure 12-30 has a negative slope.

EXAMPLE 12-7 Interpreting a Phase Diagram

A sample of ice is maintained at 1 atm and at a temperature represented by point *P* in Figure 12-30. Describe what happens when (a) the temperature is raised, at constant pressure, to point *R*, and (b) the pressure is raised, at constant temperature, to point *Q*. The sketches Figure 12-31 suggest the conditions at points *P*, *Q*, and *R*.



◀ FIGURE 12-31
Example 12-7 illustrated
A sample of pure water is confined in a cylinder by a freely moving piston surmounted by weights to establish the confining pressure. Sketched here are conditions at the points labeled *P*, *Q*, and *R* in Figure 12-30. The transition from point *P* to *Q* is accomplished by changing the pressure at constant temperature (isothermal). The transition from point *P* to *R* is accomplished by changing the temperature at constant pressure (isobaric).

Analyze

Recall that the lines separating the different phases represent coexistence lines. At these coexistence lines, the system is a mixture of both phases. On either side of those lines, the system is in that particular phase. Also recall that as the system moves from one phase to another at the coexistence lines, the temperature remains constant until all of one phase is converted to another.

Solve

(a) When the temperature reaches a point on the fusion curve *OD* (0 °C), ice begins to melt. The temperature remains constant as ice is converted to liquid. When melting is complete, the temperature

(continued)

again increases. No vapor appears in the cylinder until the temperature reaches 100 °C, at which point the vapor pressure is 1 atm. When all the liquid has vaporized, the temperature is again free to rise to a final value of *R*.

(b) Because solids are not very compressible, very little change occurs until the pressure reaches the point of intersection of the constant-temperature line *PQ* with the fusion curve *OD*. Here melting begins. A significant *decrease* in volume occurs (about 10%) as ice is converted to liquid water. After melting, additional pressure produces very little change because liquids are not very compressible.

Assess

Phase diagrams are very useful for understanding the conditions needed to observe the different phases of matter. We should now be able to use the phase diagram in Figure 12-30 to determine the pressure required to observe sublimation instead of melting.

PRACTICE EXAMPLE A: With as much detail as possible, describe the phase changes that would occur if a sample of water represented by point *R* in Figure 12-30 were brought first to point *P* and then to point *Q*.

PRACTICE EXAMPLE B: Draw a sketch showing the condition prevailing along the line *PR* when 1.00 mol of water has been brought to the point where exactly one-half of it has vaporized. Compare this to the condition at point *R* in Figure 12-31, assuming that this is also based on 1.00 mol of water. For example, is the volume of the system the same as that in Figure 12-31? If not, is it larger or smaller, and by how much? Assume that the temperature at point *R* is the same as the critical temperature of water and that water vapor behaves as an ideal gas.

12-7 CONCEPT ASSESSMENT

One method of restoring water-damaged books after a fire is extinguished in a library is by "freeze drying" them in evacuated chambers. Describe how this method might work.

12-5 Network Covalent Solids and Ionic Solids

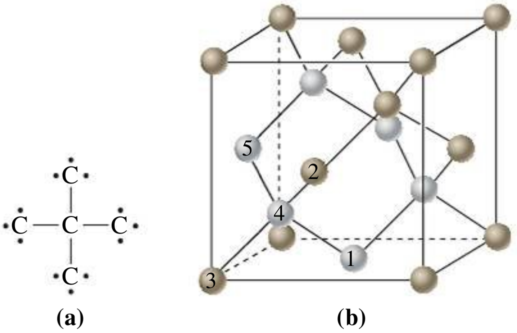
In most covalent substances, intermolecular forces are quite weak compared with the bonds between atoms within molecules. This is why covalent substances of low molecular mass (those with weak dispersion forces) are generally gaseous at room temperature. Others, usually of somewhat higher molecular masses (with stronger dispersion forces), are liquids. Still others are solids with moderately low melting points. An example of such a trend are the room-temperature states at 1 atm pressure of chlorine (a gas), bromine (a liquid), and iodine (a solid).

Network Covalent Solids

In a few substances, known as **network covalent solids**, covalent bonds extend throughout a crystalline solid. In these cases, the entire crystal is held together by strong forces. Consider, for example, two of the allotropic forms in which pure carbon occurs—diamond and graphite.

Diamond Figure 12-32 shows one way that carbon atoms can bond one to another in a very extensive array or crystal. The two-dimensional Lewis

▶ Another silicon-containing network covalent solid is ordinary silica—silicon dioxide, SiO_2.



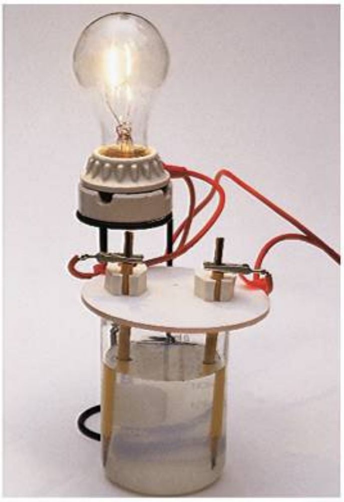
▶ FIGURE 12-32
The diamond structure
(a) A portion of the Lewis structure, **(b)** The crystal structure shows each carbon atom bonded to four others in a tetrahedral fashion. The segment of the entire crystal shown here is called a unit cell.

KEEP IN MIND

that four bonds directed from a central atom to the corners of a tetrahedron correspond to the sp^3 hybridization scheme.

structure (Fig. 12-32a) is useful only in suggesting that the bonding scheme involves ever-increasing numbers of C atoms leading to a giant molecule. It does not give any insight into the three-dimensional structure of the molecule. For this, we need the portion of the crystal shown in Figure 12-32(b). Each atom is bonded to four others. Atoms 1, 2, and 3 lie in a plane, with atom 4 above the plane. Atoms 1, 2, 3, and 5 define a tetrahedron with atom 4 at its center. When viewed from a particular direction, a nonplanar hexagonal arrangement of carbon atoms (gray) is also seen.

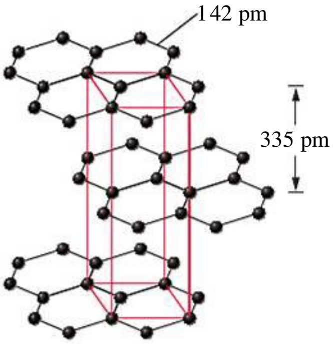
If silicon atoms are substituted for half the carbon atoms in this structure, the resulting structure is that of silicon carbide (carborundum). Both diamond and silicon carbide are extremely hard, and this accounts for their extensive use as abrasives. In fact, diamond is the hardest substance known. To scratch or break diamond or silicon carbide crystals, covalent bonds must be broken. These two materials are also nonconductors of electricity and do not melt or sublime except at very high temperatures. SiC sublimes at 2700 °C, and diamond melts above 3500 °C.



▲ **Graphite conducts electricity** Delocalized electons in graphite allow the conduction of electricity. In the photo, pencil "lead,"a mixture of graphite and clay, is used as electodes to complete the circuit.The beaker contains a solution of ions that carry the current between the pencil electrodes.

Graphite Carbon atoms can bond together to produce a solid with properties very different from those of diamond. In graphite, bonding involves the orbital set $sp^2 + p$. The three sp^2 orbitals are directed in a plane at angles of 120 °C, and the p orbitals overlap in the manner described for carbon atoms in benzene, C_6H_6 (see Figure 11-29). Thus, the p electrons are delocalized—that is, not restricted to the region between two C atoms but shared among many C atoms within a plane of C atoms. This type of bonding produces the crystal structure shown in Figure 12-33. Each carbon atom forms strong covalent bonds with three neighboring carbon atoms in the same plane, giving rise to layers of carbon atoms in a hexagonal arrangement. Bonding within layers is strong, but the intermolecular forces between layers are the much weaker van der Waals forces. We can see this through bond distances. The C—C bond distance within a layer is 142 pm (compared with 139 pm in benzene); between layers, it is 335 pm.

Its unique crystal structure gives graphite some distinctive properties. Because bonding between layers is weak, the layers can glide over one another rather easily. As a result, graphite is a good lubricant, either in dry form or in an oil suspension.* If a mild pressure is applied to a piece of graphite, layers of the graphite flake off; this is what happens when we use a graphite pencil. Also, because the p electrons are delocalized, they migrate through the planes of carbon atoms when an electric field is applied; graphite conducts electricity. An important use of graphite is as electrodes in batteries and in industrial electrolysis. Diamond is not an electrical conductor because all its valence electrons are localized or permanently fixed into single covalent bonds.



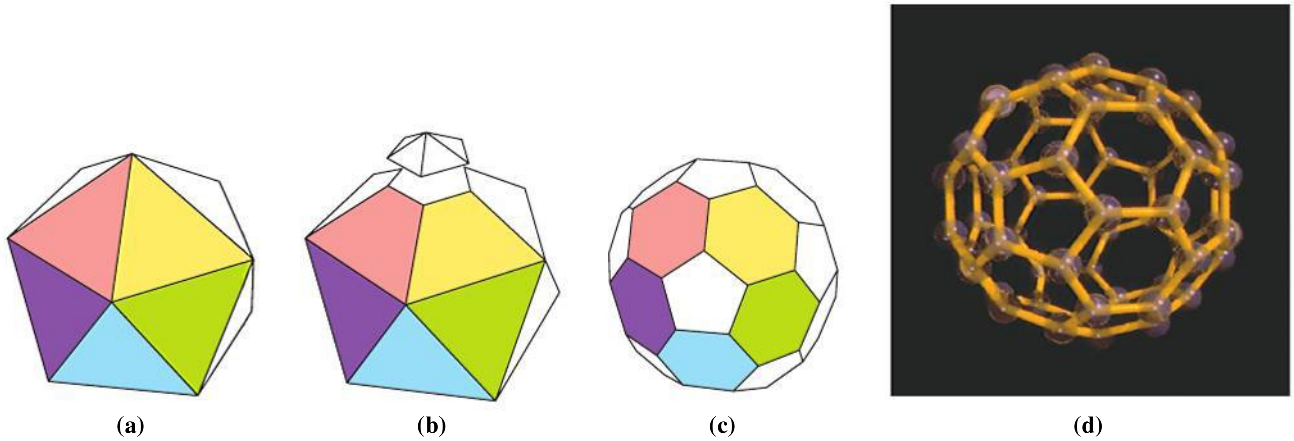
▲ FIGURE 12-33
The graphite structure

Other Allotropes of Carbon

In 1985, the first of what is now known to be an extensive series of allotropes of carbon was discovered. In experiments designed to mimic conditions found near red-giant stars, a number of carbon-containing molecules were discovered and characterized through mass spectroscopy. The strongest peak in the mass spectrum came at 720 u, corresponding to the molecule C_{60}. For a time, proposing a plausible structure for this molecule proved to be a challenge. Neither diamond- nor graphite-type structures could account for a molecule with 60 carbon atoms because "dangling" bonds would remain at the edges of the structures. The structure that was finally proposed, and confirmed by X-ray crystallography, is that of a *truncated icosahedron*—a three-dimensional figure composed of 12 pentagonal and 20 hexagonal faces, with a carbon atom at each of its 60 vertices (Fig. 12-34). This figure resembles a soccer ball and

---

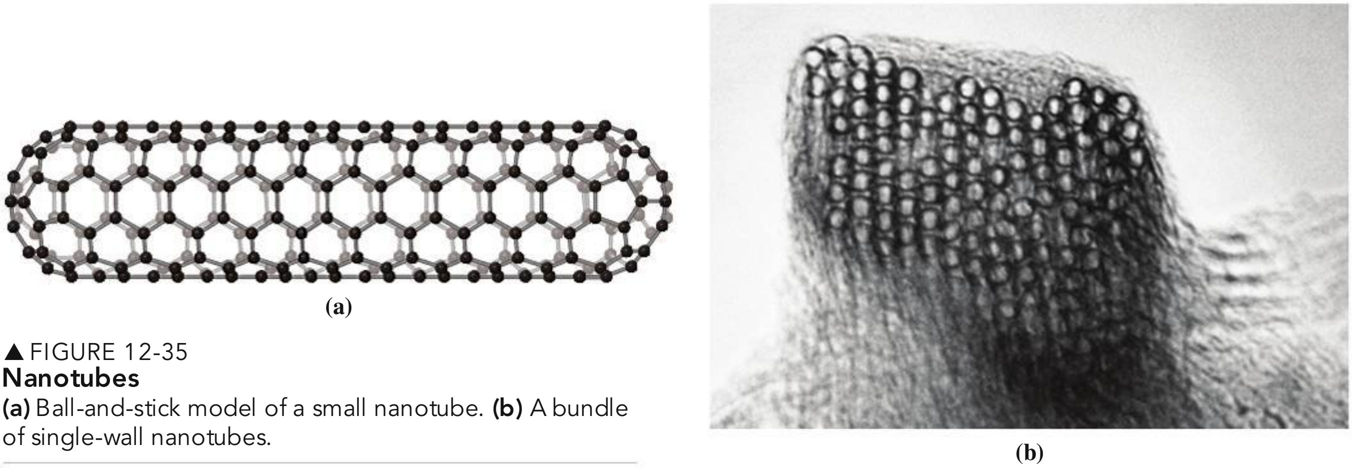
*The lubricating properties of graphite also appear to depend on the presence of molecules between the layers of carbon atoms. When graphite is strongly heated in a vacuum it becomes a much poorer lubricant.



▲ FIGURE 12-34
Fullerenes
(a) An icosahedron, a shape formed by 20 equilateral triangles. Five triangles meet at each of the 12 vertices. **(b)** Truncating or cutting off a vertex reveals a new pentagonal face. **(c)** The truncated icosahedron. Twelve pentagons have replaced the original 12 vertices, and the 20 equilateral triangles have been replaced by 20 hexagons. **(d)** The C_{60} molecule.

also certain geodesic domes. In fact, the resemblance to the geodesic dome led first to the proposed name "buckminsterfullerenes," then simply, *fullerenes,* and finally the colloquial expression "buckyballs." (The geodesic dome is an architectural form pioneered by R. Buckminster Fuller.) Since 1985, many other fullerenes have been discovered, including C_{70}, C_{74}, and C_{82}. Fullerenes can also form compounds, some by attaching atoms or groups of atoms to their surfaces, others by encasing an atom inside the fullerene structure. To date, several thousand fullerene compounds have been prepared.

Research on fullerenes has led to the discovery of a related type of carbon allotrope—*nanotubes.* A nanotube can be thought of as a two-dimensional array of hexagonal rings of carbon atoms, which is called a graphene sheet. An analogous macroscopic structure is a sheet of chicken wire. Now imagine rolling the graphene sheet into a cylinder (something that a section cut from a roll of chicken wire seems to do so naturally). Finally, cap off each end of the cylindrical graphene sheet with half of a fullerene (Fig. 12-35). The diameters of these tubes are of the order of a few nanometers (hence the name *nano*tube). Their lengths can vary from several nanometers to a micrometer or more. Nanotubes possess



▲ FIGURE 12-35
Nanotubes
(a) Ball-and-stick model of a small nanotube. **(b)** A bundle of single-wall nanotubes.

unusual electronic and mechanical properties that offer the promise of some applications in the macroscopic world and probably many more in the submicroscopic world of *nanotechnology*. For example, nanotubes might one day be used to form the molecular wires of nanoscale electronic devices.

Ionic Solids

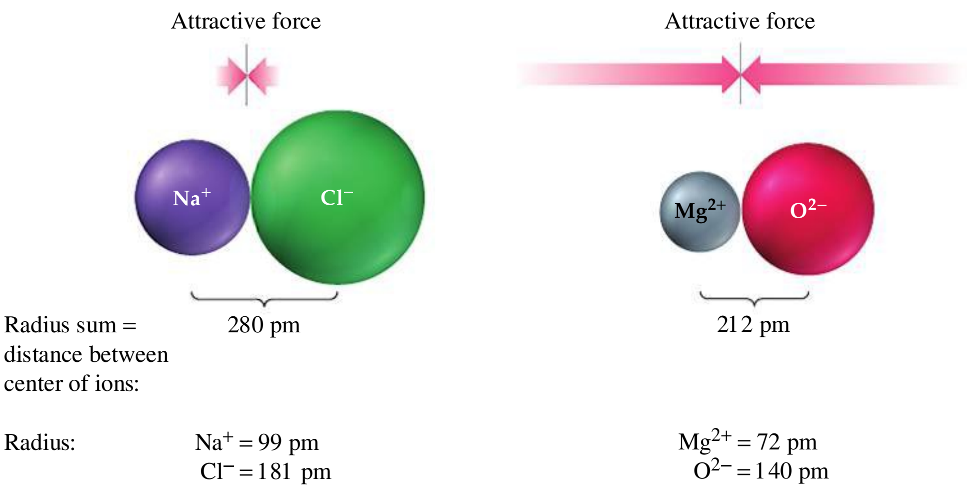
When predicting properties of an ionic solid, we often face this question: How difficult is it to break up an ionic crystal and separate its ions? This question is addressed by the *lattice energy* of a crystal. Let us define **lattice energy** as the energy given off when separated *gaseous* ions—positive and negative—come together to form *one mole* of a *solid* ionic compound. Lattice energies can be useful in making predictions about the melting points and water solubilities of ionic compounds. We will examine how to calculate lattice energies in Section 12-9. At times, however, we need to make only *qualitative* comparisons of *interionic forces*, and the following generalization works quite well.

> The attractive force between a pair of oppositely charged ions increases with increased charge on the ions and with decreased ionic sizes.

This idea is based on Coulomb's law (Appendix B) and illustrated in Figure 12-36.

For most ionic compounds, lattice energies are great enough that ions do not readily detach themselves from the crystal and pass into the gaseous state. Ionic solids do not sublime at ordinary temperatures. We can melt ionic solids by supplying enough thermal energy to disrupt the crystalline lattice. In general, the higher the lattice energy of an ionic compound, the higher is its melting point.

The energy required to break up an ionic crystal when it dissolves results from the interaction of ions in the crystal with molecules of the solvent. The extent to which an ionic solid dissolves in a solvent, however, depends only in part on the lattice energy of the ionic solid. As a rough rule, though, the lower the lattice energy, the greater the quantity of an ionic solid that can be dissolved in a given quantity of solvent.



▲ FIGURE 12-36
Interionic forces of attraction
Because of the higher charges on the ions and the closer proximity of their centers, the interionic attractive force between Mg^{2+} and O^{2-} is about seven times as great as between Na^+ and Cl^-.

EXAMPLE 12-8 Predicting Physical Properties of Ionic Compounds

Which has the higher melting point, KI or CaO?

Analyze

Trends in melting points, just as we observed for boiling points, depend on intermolecular forces. For ionic compounds the melting points are dependent on the interionic forces, which are related to Coulomb's law.

Solve

Ca^{2+} and O^{2-} are more highly charged than K^+ and I^-. Also, Ca^{2+} is smaller than K^+, and O^{2-} is smaller than I^-. We would expect the interionic forces in crystalline CaO to be much larger than in KI. CaO should have the higher melting point. (The observed melting points are 677 °C for KI and 2590 °C for CaO.)

Assess

We see that two factors contribute to the interionic forces in this problem. The first is the charge and the second is the radius of each ion.

PRACTICE EXAMPLE A: Cite one ionic compound that you would expect to have a lower melting point than KI and one with a higher melting point than CaO.

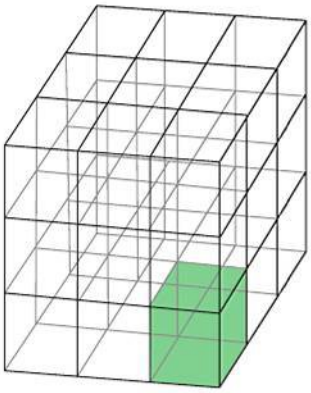
PRACTICE EXAMPLE B: Which would you expect to have the greater solubility in water, NaI or $MgCl_2$? Explain.

12-6 Crystal Structures

Crystals, solid structures having plane surfaces, sharp edges, and regular geometric shapes, have aroused interest from earliest times, whether as ice, rock salt, quartz, or gemstones. Only in relatively recent times have we come to a fundamental understanding of the crystalline state. This understanding started with the invention of the optical microscope and was greatly expanded following the discovery of X-rays. The key idea, now supported by countless experiments, is that the regularity observed in crystals at the macroscopic level is due to an underlying regular pattern in the arrangement of atoms, ions, or molecules.

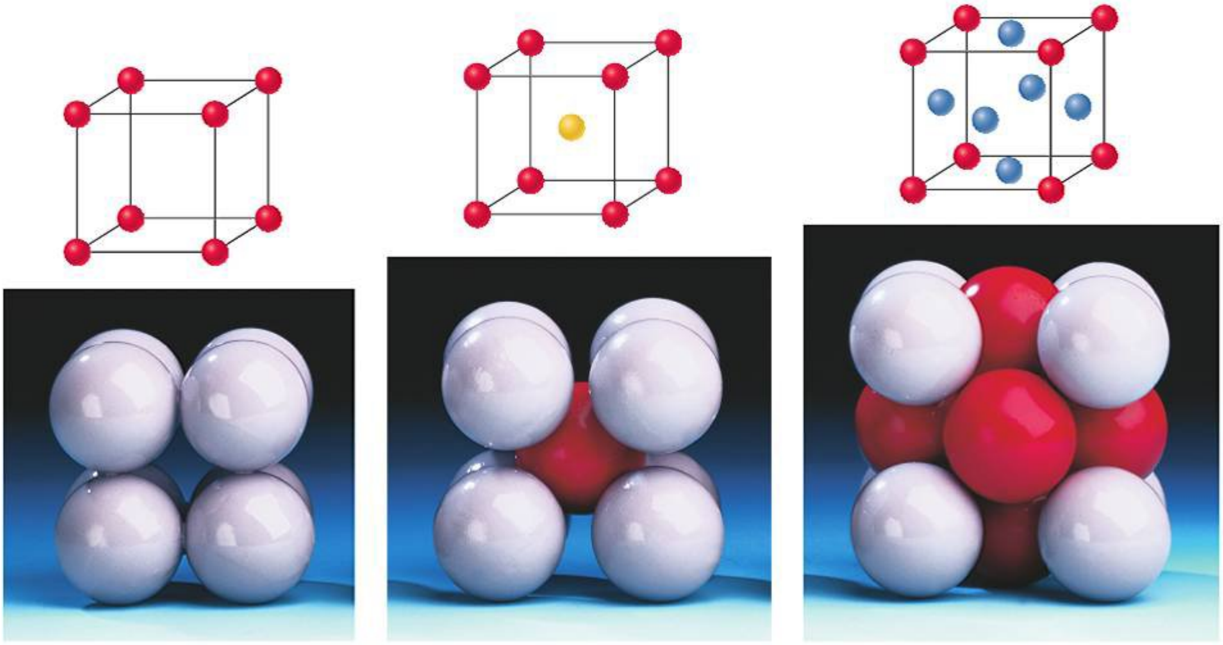
Crystal Lattices

You can probably think of a number of situations in which you have had to deal with repeating patterns in one or two dimensions. These might include projects like stringing beads to make a necklace, wallpapering a room, or creating a design with floor tiles. The structures of crystals, however, must be described through *three*-dimensional patterns. These patterns are outlined against a framework called a *lattice*, comprising the intersections of three sets of parallel planes. Figure 12-37 shows the special case for a lattice in which the planes are equidistant and mutually perpendicular (intersecting at 90° angles). This is called a *cubic* lattice, and it can be used to describe a number of crystals. For other crystals, the appropriate lattice may involve planes that are not equidistant or that intersect at angles other than 90°. In all, there are seven possibilities for crystal lattices, but we will emphasize only the cubic lattice.



▲ FIGURE 12-37
The cubic lattice
One parallelepiped formed by the intersection of mutually perpendicular planes is shaded in green—it is a cube. An endless lattice can be generated by simple displacements of the green cube in the three perpendicular directions (that is, left and right, up and down, and forward and backward).

Lattice planes intersect to produce three-dimensional figures having six faces arranged in three sets of parallel planes. These figures are called *parallelepipeds*. In Figure 12-37, the parallelepipeds are cubes. A parallelepiped called the **unit cell** can be used to generate the entire lattice by replicating it along the three perpendicular directions. (Consider a two-dimensional analogy: A single floor tile is like a unit cell and, wherever the first tile is placed, the entire floor can be covered by adding identical tiles in the two perpendicular directions from the initial one.) Where possible, we arrange the three-dimensional space lattice so that the centers of the structural particles of the crystal (atoms, ions, or molecules) are situated at lattice points. If a unit cell has structural particles only at its corners, it is called a *primitive* or simple unit cell, because it is the simplest unit cell we



Simple cubic

Body-centered cubic

Face-centered cubic

▲ FIGURE 12-38

Unit cells in the cubic crystal system

In the line-and-ball drawings in the top row, only the centers of spheres (atoms) are shown at their respective positions in the unit cells. The space-filling models in the bottom row show contacts between spheres (atoms). In the simple cubic cell, spheres come into contact along each edge. In the body-centered cubic (bcc) cell, contact of the spheres is along the cube diagonal. In the face-centered cubic (fcc) cell, contact is along the diagonal of each face. The spheres shown here are identical atoms; color is used only for emphasis.

can consider. But some unit cells have more structural particles than those found at its corners. In the **body-centered cubic (bcc)** structure, there is a structural particle at the center of the cube as well as at each corner of the unit cell. In a **face-centered cubic (fcc)** structure, there is a structural particle at the center of each face as well as at each corner. These unit cells are shown in Figure 12-38.

Closest Packed Structures

Unlike boxes, which can be stacked to fill all space, when spheres are stacked together, there must always be some unfilled space. In some arrangements, however, the spheres come into as close contact as possible, and the volume of the holes, or voids, is at a minimum. These arrangements are known as closest packed structures and are the basis of a number of crystal structures.

To analyze the closest packed structures in Figure 12-39(a), imagine one layer of spheres, layer A (red), in which each sphere is in contact with six others arranged in a hexagonal fashion around it. Among the spheres, there are holes. The hole between three spheres resembling a triangle is called a *trigonal hole* (Fig. 12-39b). Once the first sphere is placed in the next layer, layer B (yellow), the entire pattern for that layer is fixed. Again, there are holes in layer B, but the holes are of two different types. *Tetrahedral holes* fall directly over *spheres* in layer A, and *octahedral holes* fall directly over *holes* in layer A (Fig. 12-39b).

There are two possibilities for C, the third layer (Fig. 12-39a). In one arrangement, called **hexagonal closest packed (hcp)**, all the tetrahedral holes are covered. Layer C is identical to layer A, and the structure begins to repeat itself. In the other arrangement, called **cubic closest packed**, all the octahedral holes are covered. The spheres in layer C (blue) are out of line with those in layer A. Only when the fourth layer is added does the structure begin to repeat itself.

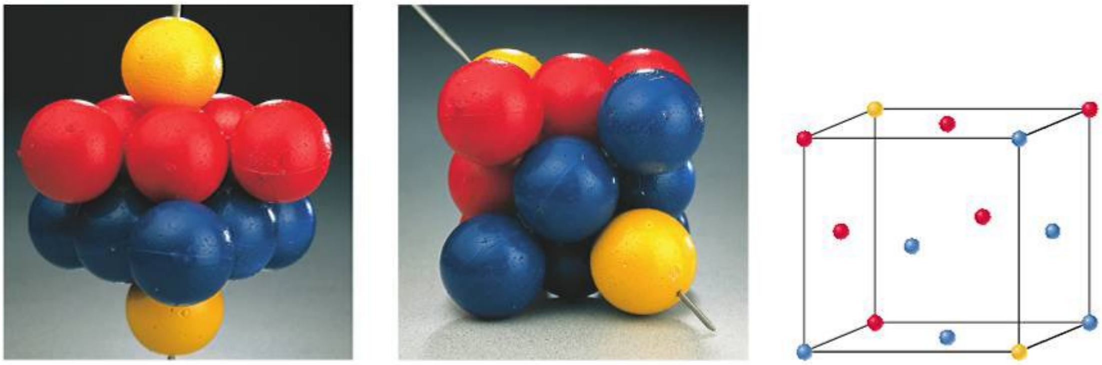
(a) Spheres in layer A are red. Those in layer B are yellow, and in layer C, blue. **(b)** The holes in closest packed structures. The trigonal hole is formed by three spheres in one of the layers. The tetrahedral hole is formed when a sphere in the upper layer sits in the dimple of the lower layer. The octahedral hole is formed between two groups of three spheres in two layers.

Study Figure 12-40 and you will see that the cubic closest packed structure has a face-centered cubic unit cell. The unit cell of the hexagonal closest packed structure is shown in Figure 12-41. In both the hcp and fcc structures, holes account for only 25.96% of the total volume. Another possibility in which spheres are closely packed but not in a closest packed arrangement has a body-centered cubic unit cell. In this structure, holes account for 31.98% of



▲ FIGURE 12-40

A face-centered cubic unit cell for the cubic closest packing of spheres
The 14 spheres on the left are extracted from a larger array of spheres in a cubic closest packed structure. The two middle layers each have six atoms; the top and bottom layers, one. Rotation of the group of 14 spheres reveals the fcc unit cell (right).

TABLE 12.6 Four Ways of Packing Identical Spheres in Cubic System

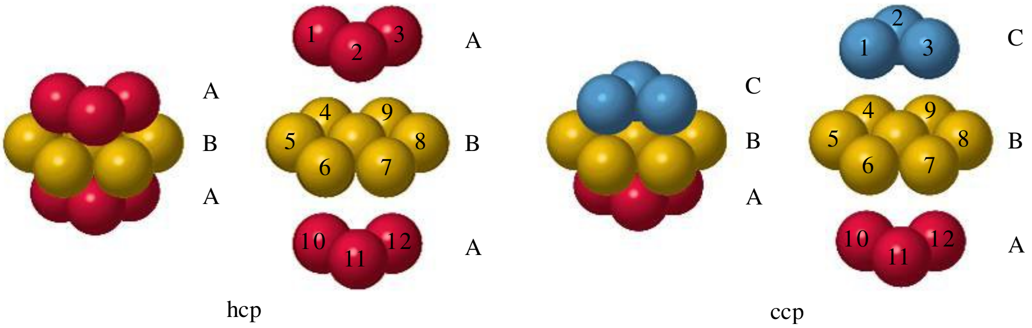
Unit Cell	Coordination Number	Atoms per Unit Cell	Volume Occupied, %	Examples
Simple cubic	6	1	52	Po
Body-centered cubic (bcc)	8	2	68	Fe, Na, K, W
Hexagonal closest packed (hcp)	12	2	74	Cd, Mg, Ti, Zn
Face-centered cubic (fcc)	12	4	74	Ag, Cu, Pb

Note: Face-centered cubic (fcc) is equivalent to cubic closest packed (ccp).

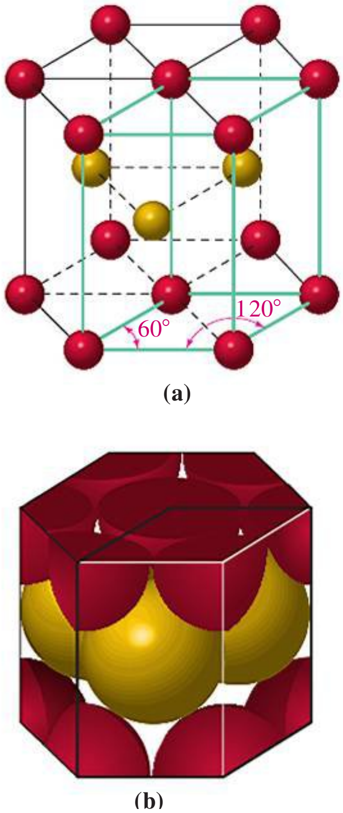
the total volume. The best examples of crystal structures based on the packing of spheres are found among the metals. Some examples are listed in Table 12.6.

Coordination Number and Number of Atoms per Unit Cell

In crystals with atoms as their structural units, each atom is in contact with several others. For example, can you see in Figure 12-38 that the center atom in the bcc unit cell is in contact with each corner atom? The number of atoms with which a given atom is in contact is called its *coordination number*. For the bcc structure, this is 8; for the fcc and hcp structures, the coordination number is 12. The easiest way to visualize the coordination number 12 is from the layering of spheres described in Figure 12-39. Each sphere is in contact with *six* others in the same layer, *three* in the layer above, and *three* in the layer below.



▲ **Illustrating the coordination number for the hcp and ccp structures**



▲ FIGURE 12-41

The hexagonal closest packed (hcp) crystal structure
(a) A unit cell is highlighted in heavy green lines. The atoms that are part of that cell are joined in solid lines. Note that the unit cell is a parallelepiped but not a cube. Three adjoining unit cells are depicted. The highlighted unit cell and broken-line regions together show the layering (ABA) described in Figure 12-39. **(b)** The hexagonal prism showing parts of the shared spheres at the corners and the single sphere at the center of the unit cell.

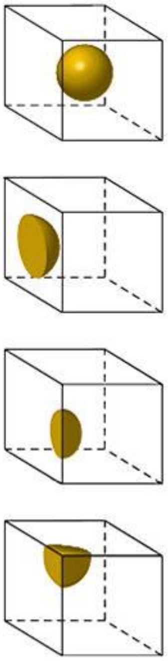
▲ FIGURE 12-42
Apportioning atoms among cubic unit cells
(a) Eight unit cells are outlined. Attention is directed to the blue-shaded unit cell. For clarity, only the centers of two atoms are pictured. The atom in the center of the blue cell belongs entirely to that cell. The corner atom is seen to be shared by all eight unit cells. **(b)** The shared spheres of a body-centered unit cell. **(c)** The shared spheres of a face-centered unit cell. **(d)** The shared spheres of a simple cubic unit cell. The spheres shown here are identical atoms; color is used only for emphasis.



▲ How spheres are shared between or among unit cells. For a sphere in the middle of the unit cell, there is no sharing; on a face 1/2 of the sphere is in the unit cell; at an edge only 1/4 of the sphere is in the unit cell; and in a corner only 1/8 is contained within the unit cell.

Although it takes nine atoms to draw the bcc unit cell, it is wrong to conclude that the unit cell consists of nine atoms. As shown in Figure 12-42(a), only the center atom belongs *entirely* to the bcc unit cell. The other atoms are shared with other unit cells. The corner atoms are shared among eight adjoining unit cells. Only one-eighth of each corner atom should be thought of as belonging entirely to a given unit cell (Fig. 12-42b). Thus, the eight corner atoms collectively contribute the equivalent of *one* atom to the unit cell. The total number of atoms in a bcc unit cell, then, is *two* $[\text{that is, } 1 + (8 \times \frac{1}{8})]$. For the hcp unit cell of Figure 12-41, we also get *two* atoms per unit cell if we use the correct counting procedure. The corner atoms account for $\frac{1}{8} \times 8 = 1$ atom, and the central atom belongs entirely to the unit cell. In the fcc unit cell, the corner atoms account for $\frac{1}{8} \times 8 = 1$ atom, and those in the center of the faces for $\frac{1}{2} \times 6 = 3$ atoms. The fcc unit cell contains *four* atoms (Fig. 12-42c). The simple cubic unit cell contains only *one* atom per unit cell (Fig. 12-42d).

12-2 ARE YOU WONDERING...

How to calculate the volume of the holes in a structure?

To illustrate this, consider the bcc structure. The ratio of the occupied volume to the unit cell volume is

$$f_{\text{v}} = \frac{\text{volume of spheres in unit cell}}{\text{volume of unit cell}}$$

If the radius of the atom is r, the volume of a sphere is $(4/3)\pi r^3$, and as shown in Figure 12-45 on page 536 the cube edge l is $r(4/\sqrt{3})$. Based on two complete spheres in the unit cell, we have

$$f_{\text{v}} = \frac{2 \times (4/3)\pi r^3}{[r(4/\sqrt{3})]^3} = 0.6802$$

Thus, 68.02% of the unit cell is occupied and 31.98% of the unit cell is empty. Note also that this percentage of empty space is the same regardless of the radius of the sphere.

X-Ray Diffraction

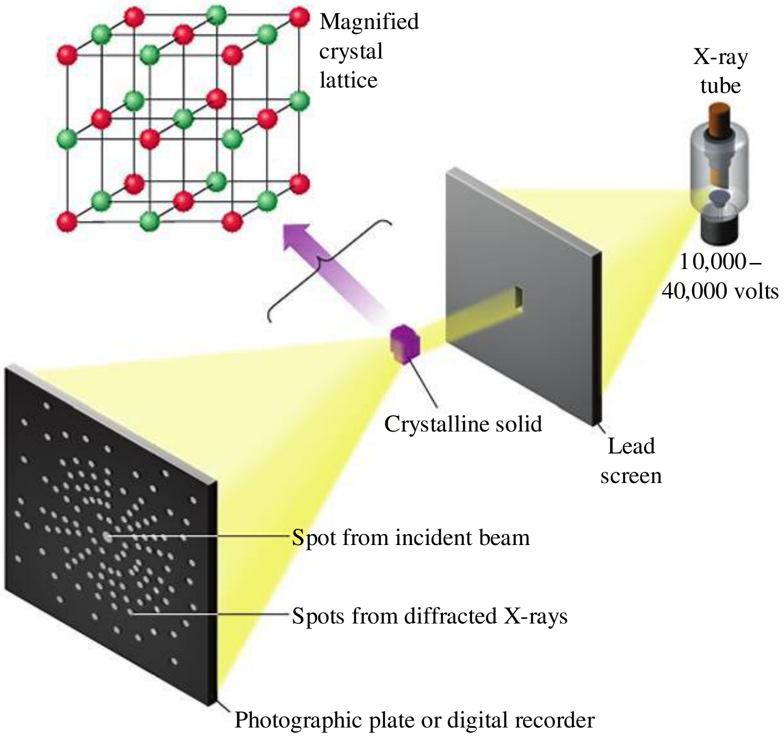
We can see macroscopic objects by using visible light and our eyes. To "see" how atoms, ions, or molecules are arranged in a crystal requires light of much shorter wavelength. When a beam of X-rays encounters atoms, the X-rays interact with electrons in the atoms and the original beam is scattered in all directions. The pattern of this scattered radiation is related to the distribution of electronic charge in the atoms and/or molecules. The scattered X-rays can produce a visible pattern, as on a photographic film, and it is then possible to infer the microscopic structure of the substance from this visible pattern. How successful we are in making inferences depends on the amount of the scattered radiation recovered, that is, on how much "information" is gathered. The power of the X-ray diffraction method has been greatly increased by the use of high-speed computers to process vast amounts of X-ray data.

◀ The X-ray diffraction method was originated by Max von Laue (Nobel Prize, 1914) but carried further by the Braggs. William Lawrence Bragg was only 25 years old when he and his father, William Henry Bragg, won the Nobel Prize in 1915.

Figure 12-43 suggests a method of scattering X-rays from a crystal. X-ray data can be explained by a geometric analysis proposed by W. H. Bragg and W. L. Bragg in 1912 and illustrated in Figure 12-44. The figure shows two rays in a monochromatic (single-wavelength) X-ray beam, labeled *a* and *b*. Wave *a* is diffracted, or scattered, by one plane of atoms or ions in a crystal and wave *b* from the next plane below. Wave *b* travels a greater distance than wave *a*. The additional distance is $2d \sin\theta$. The intensity of the scattered radiation will be greatest if waves *a* and *b* reinforce each other, that is, if their crests and troughs line up. To satisfy this requirement, the additional distance traveled by wave *b* must be an integral multiple of the wavelength of the X-rays.

$$n\lambda = 2d\sin\theta \qquad \textbf{(12.5)}$$

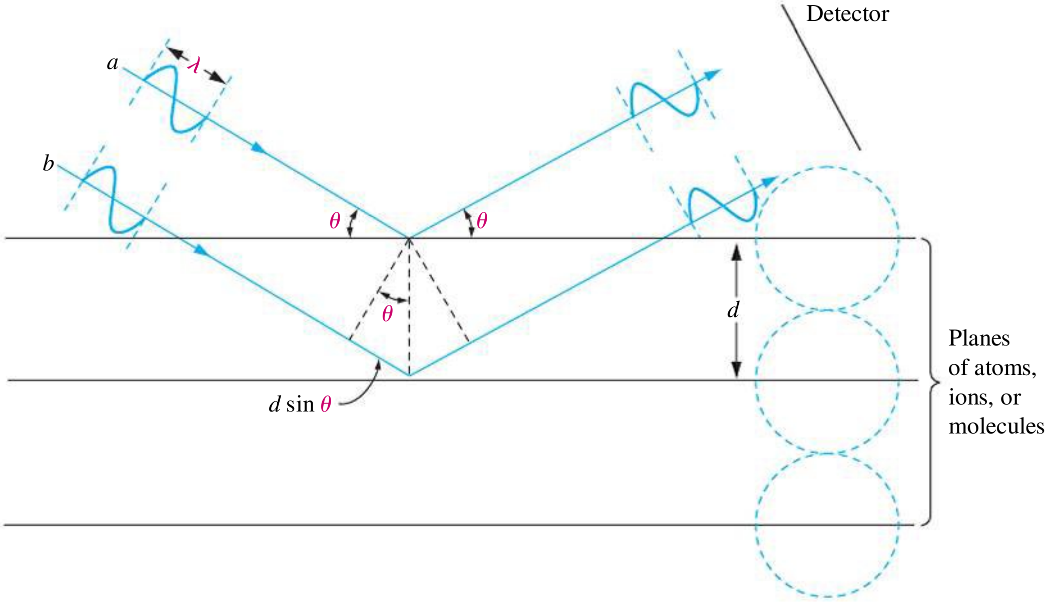
From the measured angle θ yielding the maxmum intensity for the scattered X-rays, and the X-ray wavelength (λ), we can calulate the spacing (d) between



▲ FIGURE 12-43

Diffraction of X-rays by a crystal

In X-ray diffraction, the scattering is usually from no more than 20 planes deep in a crystal. The size of the single crystal is to have enough of the surface available for diffraction, yet the diffraction is dominated by a few of the surface planes.



▲ FIGURE 12-44
Determination of crystal structure by X-ray diffraction
The two triangles outlined by dashed lines are identical. The hypotenuse of each triangle is equal to the interatomic distance, *d*. The side opposite the angle θ thus has a length of $d \sin\theta$. Wave *b* travels farther than wave *a* by the distance $2d \sin\theta$.

atomic planes. With different orientations of the crystal, we can determine atomic spacings and electron densities for different directions through the crystal, in short, the crystal structure.

Once a crystal structure is known, certain other properties can be determined by calculation. Example 12-9 shows the determination of a metallic

EXAMPLE 12-9 Using X-Ray Data to Determine an Atomic Radius

At room remperature, iron crystallizes in a bcc structure. By X-ray diffraction, the edge of the cubic cell corresponding to Figure 12-45 is found to be 287 pm. What is the radius of an iron atom?

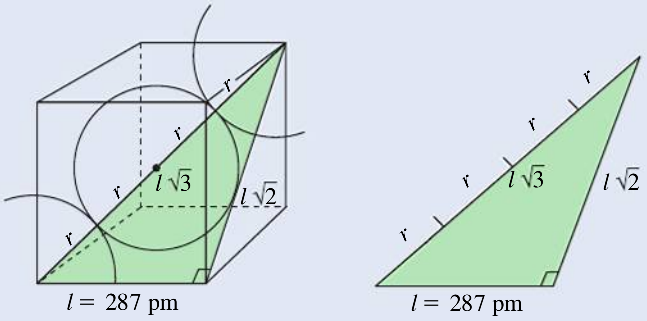
Analyze

Nine atoms are associated with a bcc unit cell. One atom is located at each of the eight corners of the cube and one at the center. The three atoms along a diagonal through the cube are in contact. The length of the cube diagonal (the distance from the farthest upper-right corner to the nearest lower-left corner) is four times the atomic radius. Also shown in Figure 12-45 is the fact the diagonal of a cube is equal to $\sqrt{3} \times l$. The length of an edge, *l*, is what is given.

Solve

Setting the length of the cube diagonal, in terms of atomic radii, equal to the expression relating the diagonal to the cube, we have

$$4r = l\sqrt{3}$$



▲ FIGURE 12-45
Determination of the atomic radius of iron—Example 12-9 illustrated
The right triangle must conform to the Pythagorean formula $a^2 + b^2 = c^2$. That is, with l as an edge of the cube, $(l)^2 + (l\sqrt{2})^2 = (l\sqrt{3})^2$, or $(l)^2 + 2(l)^2 = 3(l)^2$.

which is used to solve for the atomic radius of an iron atom:

$$r = \frac{\sqrt{3} \times 287 \text{ pm}}{4} = \frac{1.732 \times 287 \text{ pm}}{4} = 124 \text{ pm}$$

Assess

We see that it is important to know the atomic arrangement for each basic unit cell and to know that atoms at the corners are shared between unit cells.

PRACTICE EXAMPLE A: Potassium crystallizes in the bcc structure. What is the length of the unit cell in this structure? Use the metallic radius of potassium given in Figure 9-9.

PRACTICE EXAMPLE B: Aluminum crystallizes in an fcc structure. Given that the atomic radius of Al is 143.1 pm, what is the volume of a unit cell?

radius, and Example 12-10 estimates the density of a crystalline solid. For both of these calculations, we need to sketch, or in some way visualize, a unit cell of the crystal. In particular, we need to see which atoms are in direct contact.

EXAMPLE 12-10 Relating Density to Crystal Structure Data

Use data from Example 12-9, together with the molar mass of Fe and the Avogadro constant, to calculate the density of iron.

Analyze

To calculate the density, we need the mass of the unit cell (in grams) and its volume (in cm^3). From Table 12.6, we find that there are *two* Fe atoms per bcc unit cell, which we can use to calculate the mass of the unit cell. In Example 12-9, we saw that the length of a unit cell is $l = 287 \text{ pm} = 287 \times 10^{-12} \text{ m} = 2.87 \times 10^{-8} \text{ cm}$, which we can use to find the density of iron.

Solve

We need the mass of these two atoms, and the key to getting this is a conversion factor based on the fact that $1 \text{ mol Fe} = 6.022 \times 10^{23} \text{ Fe atoms} = 55.85 \text{ g Fe}$.

$$m = 2 \text{ Fe atoms} \times \frac{55.85 \text{ g Fe}}{6.022 \times 10^{23} \text{ Fe atoms}} = 1.855 \times 10^{-22} \text{ g Fe}$$

The volume of the unit cell is $V = l^3 = (2.87 \times 10^{-8})^3 \text{ cm}^3$. Density is the ratio of mass to volume.

$$\text{density of Fe} = \frac{m}{V} = \frac{1.855 \times 10^{-22} \text{ g Fe}}{2.36 \times 10^{-23} \text{ cm}^3} = 7.86 \text{ g Fe cm}^{-3}$$

Assess

The use of crystal structure data is another way we can determine the density of materials. This method is especially useful when we are studying new compounds or materials of which we have only a small quantity. The type of unit cell adopted by a metal can be deduced by using the experimental density and experimentally determined cell edge length.

PRACTICE EXAMPLE A: Use the result of Practice Example 12-9A, the molar mass of K and the Avogadro constant to calculate the density of potassium.

PRACTICE EXAMPLE B: Use the result of Practice Example 12-9B, the molar mass of Al and its density (2.6984 g cm^{-3}) to evaluate the Avogadro constant, N_A.

[*Hint:* From the volume of a unit cell and the density of Al, you can determine the mass of a unit cell. Knowing the number of Al atoms in the fcc unit cell, you can determine the mass per Al atom.]

12-8 CONCEPT ASSESSMENT

Suppose a first-order diffraction is observed at an angle θ for a particular plane of atoms by using X-rays of wavelength λ. In order to observe a second-order diffraction from the same plane of atoms at the same angle θ, the wavelength of the X-rays must be a multiple of λ. What is that multiple?

KEEP IN MIND

that cations almost always have smaller radii than anions. This was discussed in Chapter 9.

Ionic Crystal Structures

If we try to apply the packing-of-spheres model to an ionic crystal, we run into two complications: (1) Some of the ions are positively charged and some are negatively charged, and (2) the cations and anions are of different sizes. What we can expect, however, is that oppositely charged ions will come into close proximity. Generally we think of them as being in contact. Like-charged ions, because of mutual repulsions, are not in direct contact. We can think of some ionic crystals as a fairly closely packed arrangement of ions of one type with holes filled by ions of the opposite charge. The relative sizes of cations and anions are important in establishing a particular packing arrangement.

A common arrangement in binary ionic solids is the face-centered cubic arrangement. Very often one of the ions, usually the anion, can be viewed as adopting the face-centered cubic structure while the cation occupies one of the holes between the closest-packed spheres. The three types of holes of the cubic closest packed structure—trigonal, tetrahedral, and octahedral—are shown in Figure 12-46. The size of the holes is related to the radius, R, of the anions used to form the structure. Figure 12-47 shows a cross section through an octahedral hole. The radius of the cation, r, that can just fit into the hole can be found by using the Pythagorean formula, as follows.

$$(2R)^2 + (2R)^2 = (2R + 2r)^2$$

$$2\sqrt{2}R = 2R + 2r$$

$$(2\sqrt{2} - 2)R = 2r$$

$$(\sqrt{2} - 1)R = r$$

$$r = 0.414\,R$$

Similar calculations can be used for tetrahedral and trigonal holes, for which $r = 0.225\,R$ and $r = 0.155\,R$, respectively. These calculations show that in the cubic closest packed structure, the octahedral hole is bigger than the tetrahedral hole.
